Qualified individuals should submit CV to: **Dr. E. Albert Reece, Chairman, Temple University School of Medicine, Department of OB/GYN/RS, Broad and Ontario Streets, Philadelphia, PA 19140.**

Temple University is an equal opportunity/ affirmative action employer.

UNIVERSITY

Choose
TEMPLE

The University of Michigan Department of Obstetrics and Gynecology, Chair

The University of Michigan is seeking an academic leader to chair its Department of Obstetrics and Gynecology. Qualifications include: an M.D. degree and Board Certification in Obstetrics and Gynecology; national recognition as a leader in Obstetrics and Gynecology; a record of scholarly accomplishment sufficient to justify a tenured faculty appointment; ability to provide direction to the teaching, research and clinical programs of an academic department in a large and complex medical center; commitment to excellence in educational programs; clinical expertise in the field; demonstrated administrative skills and substantial management experience in a medical school and/or teaching hospital setting. To respnd, please send a CV **by April 1, 1992** to: Obstetrics and Gynecology Search Committee c/o Ms. Jeanne Kin, Staff Associate, Medical Administration, M7330 Medical Science Building I, University of Michigan Medical School, Ann Arbor, MI 48109-0624. The University of Michigan is a Non-Discriminatory/Affirmative Action Employer. Women and minority candidates are encouraged to apply.

State University of New York
Health Science Center
Syracuse

MATERNAL-FETAL MEDICINE SUBSPECIALIST

The Department of Obstetrics and Gynecology of the SUNY Health Science Center at Syracuse is actively recruiting a fifth full-time Perinatologist for its Division of Maternal-Fetal Medicine.

The teaching hospital serves as the only Tertiary Care Center for the Regional Perinatal Program encompassing the 15 counties of Central New York with a population of 2.3 million.

Excellent opportunity to participate in teaching in a University based setting and collaborate in ongoing research in clinical Perinatology, Ultrasound, and Prenatal Diagnosis.

TOP SALARY, ATTRACTIVE BENEFITS PACKAGE, AND PROTECTED RESEARCH TIME.

Board eligibility/certification in Maternal-Fetal Medicine is required.

Interested candidates should send curriculum vitae to:

Robert K. Silvermar, M.D.
Division of Maternal-Fetal Medicine
SUNY Health Science Center at Syracuse
Perinatal Center
725 Irving Avenue, Suite 115
Syracuse, NY 13210
(315) 470-7196

SUNY Health Science Center is an equal opportunity, affirmative action employer.

THE DEPARTMENT OF OBSTETRICS AND GYNECOLOGY
UNIVERSITY OF WISCONSIN MEDICAL SCHOOL

is seeking applicants for two (2) full-time faculty positions for a new women's health center and academic program at its Milwaukee Clinical Campus.

Sinai Samaritan Medical Center has recently consolidated its obstetrical and gynecological services in a redesigned facility in downtown Milwaukee. The department supports a residency program, the largest perinatal service in Wisconsin (5500 deliveries), consultative ultrasound, genetic and infectious disease programs, and reproductive/endocrine services (including an IVF program). The department is affiliated with Planned Parenthood of Wisconsin and St. Luke's Medical Center in Milwaukee.

Qualifications include a board candidacy or certification in obstetrics and gynecology and a commitment to teaching residents, medical students, and clinical research. Qualifications for the two positions for GENERAL OB/GYN can take into consideration special individual interests. Special expertise of interest for the department are:

—STATEWIDE FAMILY PLANNING
(Part-time medical director, Planned Parenthood)
—OPERATIVE LAPAROSCOPY, HYSTEROSCOPY
—UROGYNECOLOGY
—OB/GYN ULTRASOUND

Private practice opportunities are also available in an associated offsite multispecialty clinic and all faculty members participate in a group practice at the institution. Contact:

Chester B. Martin, M.D.
Chairman
Department of Obstetrics and Gynecology
University of Wisconsin Medical Schl.
600 Highland Avenue, H4/654 CSC
Madison, WI 53792

Fredrik F. Broekhuizen, M.D.

OBSTETRICIAN/ GYNECOLOGIST

Large two person OB-GYN group-Park Ave. So. office, seeking dedicated BC/BE associate leading toward partnership. Large volume of obstetrics, specializing in high risk, very supportive of natural childbirth. Office colposcopy, ultrasound, fetal monitoring.

Send C.V. TO:

Marc Sklar M.D.
461 Park Ave. So.
New York, N.Y. 10016

OB/GYN

St. Elizabeth Medical Center is offering an excellent opportunity to a bright and talented OB/GYN physician. Our JCAHO facility in Northern Kentucky is ideally located close to the Cincinnati area. This opportunity will offer a teaching environment, possibilities for clinical research and hands on practice. We are a Level II facility handling an average of 3000 deliveries per year. If you are tired of private practice and working from 8-5 sounds good (on call one night per week), this is the position for you.

For more information please contact our Physician Services Director:

Joni Yeager
St. Elizabeth Medical Center
401 E. 20th Street
Covington, Kentucky 41014
(606) 292-4023

FACULTY POSITIONS
ST. JOHN'S MERCY MEDICAL CENTER
ST. LOUIS, MISSOURI
DEPARTMENT OF OBSTETRICS AND GYNECOLOGY

DIRECTOR OF ENDOSCOPIC PROCEDURES

Immediate opening for Director of Outpatient Surgery for the Department of Obstetrics and Gynecology. Candidates will be qualified to train residents in endoscopy procedures (laparoscopy, hysteroscopy, pelviscopy and use of KTP laser); general surgeons in the use of laparoscopic equipment and KTP laser; and orthopedic surgeons in the use of the KTP laser. Physician will assist in many of the above procedures and will provide verification of training to QA committees in the Department of Obstetrics and Gynecology. Private practice in specialty or subspecialty is also an option.

GYNECOLOGIC ONCOLOGIST

A BC/BE gynecologic oncologist is sought to expand services within the Department. This division provides chemotherapy, immunotherapy, surgery (both radical and nonradical) and radiation therapy. Resident education is a major component of this position. The new St. John's Mercy Cancer Care Center provides a regional patient base for the Division of Gynecology–Oncology. Research credentials a definite plus.

ST. JOHN'S MERCY MEDICAL CENTER

Is an 859 bed community, not for profit, teaching hospital with a fully accredited residency program and one of the midwest's largest obstetrical services. These positions offer an outstanding academic and professional environment with excellent compensation and benefits. Confidential inquiries may be directed to James Blythe, M.D., Chairman or write to Phil Gilbert, Administration, St. John's Mercy Medical Center, 615 South New Ballas Road, St. Louis, MO 63141. You may also call Phil Gilbert at 314-569-6116.

Director of Perinatology

Due to expansion of the scope of the oldest and most prestigious family practice residency program in the south, we are seeking a BE/BC Perinatologist for the faculty/staff. With 36 residents, this progressive program's philosophy is to provide solid training in obstetrics. The position will be multi-faceted with aspects of patient care, teaching, and private consultation, and carries the opportunity for an academic affiliation with the Medical College of Georgia. There is a dedicated antenatal testing unit. The hospital is a 417-bed tertiary care facility with Level III NICU and 2 BC Neonatologists. Approximately 4000 births are facilitated each year, with 10% deemed high risk. Enjoy the luxury of excelling in your area of expertise with good call coverage from a large group of obstetricians who handle high risk patients as part of their daily practice. Highly competitive compensation package is offered. Just 90 minutes from Atlanta, this is the second largest city in Georgia, with a population of 250,000 and a 38 county referral base. To explore this opportunity, please contact:

Joyce Campbell
Physician Services of America
2000 Warrington Way, Suite 250, Louisville, KY 40222
(800) 626-1857, ext. 238

THE HEALTH CENTER FOR WOMEN

St. Paul-Ramsey Medical Center
Ramsey Clinic

The Health Center for Women at St. Paul-Ramsey Medical Center and Ramsey Clinic is seeking out a physician specializing in obstetrics and gynecology to join the multi-disciplinary team at the Center. The Health Center for Women is a new approach to health care and was designed exclusively for women. Candidates should be board certified/eligible and possess excellent interpersonal skills. The Twin Cities of Minneapolis and St. Paul is considered one of the country's cleanest, safest and most enjoyable metropolitan areas! For more information, kindly forward your curriculum vitae to: **Loriese A. Stoll, Director of Professional Services, Ramsey Clinic, 640 Jackson Street, St. Paul, Minnesota 55101-2595, (612) 221-3067.**

DRUG ABUSE IS CHILD ABUSE

Approximately 80% of the offspring of heroin-dependent women who receive no prenatal care experience serious medical problems such as intracranial hemorrhages and respiratory distress syndrome .

Neonates exposed to cocaine in utero have been documented to experience neurobehavioral abnormalities. They tend to be irritable and easily overstimulated.

The effects of cocaine abuse have been directly linked to certain congenital anomalies in infants, including intestinal atresia, limb reductions, and brain disruptions. These infants are also at a greater risk for congenital heart, urinary tract, and genitourinary defects.

The use of amphetamines during pregnancy may increase the occurrence of cardiovascular defects in the offspring.

If your patients are abusing drugs, tell them the facts, counsel them, recommend treatment programs...help them.

Each peach tablet contains 1 mg norethindrone and 0.035 mg ethinyl estradiol. Each green tablet in 28-day regimen contains inert ingredients.

IMPORTANT NOTE—This information is a BRIEF SUMMARY of the complete prescribing information provided with the product and therefore should not be used as the basis for prescribing the product. This summary was prepared by deleting from the complete prescribing information certain text, tables and references. The physician should be thoroughly familiar with the complete prescribing information before prescribing the product.

INDICATIONS AND USAGE: PREVENTION OF PREGNANCY.

CONTRAINDICATIONS: Oral contraceptives should not be used in women who currently have the following conditions: 1. Thrombophlebitis or thromboembolic disorders. 2. A past history of deep vein thrombophlebitis or thromboembolic disorders. 3. Cerebral vascular or coronary artery disease. 4. Known or suspected carcinoma of the breast. 5. Carcinoma of the endometrium or other known or suspected estrogen-dependent neoplasia. 6. Undiagnosed abnormal genital bleeding. 7. Cholestatic jaundice of pregnancy or jaundice with prior pill use. 8. Hepatic adenomas or carcinomas. 9. Known or suspected pregnancy.

WARNINGS

Cigarette smoking increases the risk of serious cardiovascular side effects from oral contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia, and gallbladder disease, although the risk of serious morbidity or mortality is very small in healthy women without underlying risk factors. The risk of morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemias, obesity and diabetes. Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks. The information contained in this brief summary is principally based on studies carried out in patients who used oral contraceptives with higher formulations of estrogens and progestogens than those in common use today. The effect of long term use of the oral contraceptives with lower formulations of both estrogens and progestogens remains to be determined. Throughout this brief summary epidemiological studies reported are of two types: retrospective or case control studies and prospective or cohort studies. Case control studies provide a measure of the relative risk of a disease, namely a *ratio* of the incidence of a disease among oral contraceptive users to that among nonusers. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide a measure of attributable risk, which is the *difference* in the incidence of disease between oral contraceptive users and nonusers. The attributable risk does provide information about the actual occurrence of a disease in the population. For further information, the reader is referred to a text on epidemiological methods. 1. THROMBOEMBOLIC DISORDERS AND OTHER VASCULAR PROBLEMS. a. Myocardial Infarction. An increased risk of myocardial infarction has been associated with oral contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary artery disease such as hypertension, hypercholesterolemia, morbid obesity, and diabetes. The relative risk of heart attack for current oral contraceptive users has been estimated to be two to six. The risk is very low under the age of 30. Smoking in combination with oral contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women in their mid-thirties or older with smoking accounting for the majority of excess cases. Mortality rates associated with circulatory disease have been shown to increase substantially in smokers, especially in those 35 years of age and older among women who use oral contraceptives. Oral contraceptives may compound the effects of well-known risk factors, such as hypertension, diabetes, hyperlipidemias, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and cause glucose intolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see section 9 in WARNINGS). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors. b. Thromboembolism. An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to non-users to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. Cohort studies have shown the relative risk to be somewhat lower, about 3 for new cases and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease associated with oral contraceptives is not related to length of use and disappears after pill use is stopped. A two- to four-fold increase in relative risk of post-operative thromboembolic complications has been reported with the use of oral contraceptives. The relative risk of venous thrombosis in women who have predisposing conditions is twice that of women without such medical conditions. If feasible, oral contraceptives should be discontinued at least four weeks prior to and for two weeks after elective surgery of a type associated with an increase in risk of thromboembolism and during and following prolonged immobilization. Since the immediate postpartum period is also associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than four weeks after delivery in women who elect not to breast feed. c. Cerebrovascular diseases. Oral contraceptives have been shown to increase both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes), although, in general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and non-users, for both types of strokes, and smoking interacted to increase the risk of stroke. In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for nonsmokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 7.6 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk is also greater in older women. d. Dose-related risk of vascular disease from oral contraceptives. A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high density lipoproteins (HDL) has been reported with many progestational agents. A decline in serum high density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the activity of the progestogen used in the contraceptive. The activity and amount of both hormones should be considered in the choice of an oral contraceptive. Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral contraceptive agents should be started on preparations containing 0.035 mg or less of estrogen. e. Persistence of risk of vascular disease. There are two studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40-49 years who had used oral contraceptives for five or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. However, both studies were performed with oral contraceptive formulations containing 50 micrograms or higher of estrogens. 2. ESTIMATES OF MORTALITY FROM CONTRACEPTIVE USE. One study gathered data from a variety of sources which have estimated the mortality rate associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is low and below that associated with childbirth. However, smokers 35 and older and non-smokers 40 and older who use oral contraceptives have a significant increase in mortality higher than those using other methods of birth control. These facts must be weighed in conjunction with failure rates for other methods and the risk associated with subsequent pregnancy. 3. CARCINOMA OF THE REPRODUCTIVE ORGANS. Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. While there are conflicting reports most studies suggest that use of oral contraceptives is not associated with an overall increase in the risk of developing breast cancer. Some studies have reported an increased relative risk of developing breast cancer, particularly at a younger age. This increased relative risk appears to be related to duration of use. Some studies suggest that oral contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors. 4. HEPATIC NEOPLASIA. Benign hepatic adenomas are associated with oral contraceptive use, although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases/100,000 for users, a risk that increases after four or more years of use especially with oral contraceptives of higher dose. Rupture of benign, hepatic adenomas may cause death through intra-abdominal hemorrhage. Studies from Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral contraceptive users. However, these cancers are rare in the U.S. and the attributable risk (the excess incidence) of liver cancers in oral contraceptive users approaches less than one per million users. 5. OCULAR LESIONS. There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia, papilledema, or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately. 6. ORAL CONTRACEPTIVE USE BEFORE OR DURING EARLY PREGNANCY. Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. The majority of recent studies also do not indicate a teratogenic effect, particularly in so far as cardiac anomalies and limb reduction defects are concerned, when taken inadvertently during early pregnancy. The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion. It is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing oral contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral contraceptive use should be discontinued until pregnancy is ruled out. 7. GALLBLADDER DISEASE. Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral contraceptive users may be minimal. The recent findings of minimal risk may be related to the use of oral contraceptive formulations containing lower hormonal doses of estrogens and progestogens. 8. CARBOHYDRATE AND LIPID METABOLIC EFFECTS. Oral contraceptives have been shown to cause a decrease in glucose tolerance in a significant percentage of users. This effect has been shown to be directly related to estrogen dose. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the non-diabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects prediabetic and diabetic women in particular should be carefully monitored while taking oral contraceptives. A small proportion of women will have persistent hypertriglyceridemia while on the pill. As discussed earlier (see WARNINGS 1a and 1d), changes in serum triglycerides and lipoprotein levels have been reported in oral contraceptive users. 9. ELEVATED BLOOD PRESSURE. An increase in blood pressure has been reported in women taking oral contraceptives, and this increase is more likely in older oral contraceptive users and with extended duration of use. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing progestational activity. Women with a history of hypertension or hypertension-related diseases, or renal disease, should be encouraged to use another method of contraception. If women elect to use oral contraceptives, they should be monitored closely and if significant elevation of blood pressure occurs, oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives, and there is no difference in the occurrence of hypertension between former and never users. 10. HEADACHE. The onset or exacerbation of migraine or development of headache with a new pattern which is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause. 11. BLEEDING IRREGULARITIES. Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first three months of use. Non-hormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out. Some women may encounter post-pill amenorrhea or oligomenorrhea, especially when such a condition was preexistent. 12. ECTOPIC PREGNANCY. Ectopic as well as intrauterine pregnancy may occur in contraceptive failures. **PRECAUTIONS:** 1. PHYSICAL EXAMINATION AND FOLLOW UP. A complete medical history and physical examination should be taken prior to the initiation or reinstitution of oral contraceptives and at least annually during use of oral contraceptives. These physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, including cervical cytology, and relevant laboratory tests. In case of undiagnosed persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be conducted to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care. 2. LIPID DISORDERS. Women who are being treated for hyperlipidemias should be followed closely if they elect to use oral contraceptives. Some progestogens may elevate LDL levels and may render the control of hyperlipidemias more difficult. 3. LIVER FUNCTION. If jaundice develops in any woman receiving such drugs, the medication should be discontinued. Steroid hormones may be poorly metabolized in patients with impaired liver function. 4. FLUID RETENTION. Oral contraceptives may cause some degree of fluid retention. They should be prescribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention. 5. EMOTIONAL DISORDERS. Women with a history of depression should be carefully observed and the drug discontinued if depression recurs to a serious degree. 6. CONTACT LENSES. Contact lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist. 7. DRUG INTERACTIONS. Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar association, though less marked, has been suggested with barbiturates, phenylbutazone, phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines. 8. INTERACTIONS WITH LABORATORY TESTS. Certain endocrine and liver function tests and blood components may be affected by oral contraceptives: a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3, increased norepinephrine-induced platelet aggregability. b. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radio-immunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG, free T4 concentration is unaltered. c. Other binding proteins may be elevated in serum. d. Sex-binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged. e. Triglycerides may be increased. f. Glucose tolerance may be decreased. g. Serum folate levels may be depressed by oral contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives. 9. CARCINOGENESIS. See WARNINGS section. 10. PREGNANCY. Pregnancy Category X. See CONTRAINDICATIONS and WARNINGS sections. 11. NURSING MOTHERS. Small amounts of oral contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child. **INFORMATION FOR THE PATIENT: See Patient Package Insert. ADVERSE REACTIONS:** An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see WARNINGS section). Thrombophlebitis and venous thrombosis with or without embolism. Arterial thromboembolism. Pulmonary embolism. Myocardial infarction. Cerebral hemorrhage. Cerebral thrombosis. Hypertension. Gallbladder disease. Hepatic adenomas or benign liver tumors. The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug-related: Nausea. Vomiting. Gastrointestinal symptoms (such as abdominal cramps and bloating). Breakthrough bleeding. Spotting. Change in menstrual flow. Amenorrhea. Temporary infertility after discontinuation of treatment. Edema. Melasma which may persist. Breast changes: tenderness, enlargement, secretion. Change in weight (increase or decrease). Change in cervical erosion and secretion. Diminution in lactation when given immediately postpartum. Cholestatic jaundice. Migraine. Rash (allergic). Mental depression. Reduced tolerance to carbohydrates. Vaginal candidiasis. Change in corneal curvature (steepening). Intolerance to contact lenses. The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted: Pre-menstrual syndrome. Cataracts. Changes in appetite. Cystitis-like syndrome. Headache. Nervousness. Dizziness. Hirsutism. Loss of scalp hair. Erythema multiform, Erythema nodosum. Hemorrhagic eruption. Vaginitis. Porphyria. Impaired renal function. Hemolytic uremic syndrome. Acne. Changes in libido. Colitis. **OVERDOSAGE:** Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea and withdrawal bleeding may occur in females.

IN THE MANAGEMENT OF ENDOMETRIOSIS

enough is enough

Power to suppress estradiol to levels that result in effective relief

- Lowers serum estradiol to near menopausal levels within approximately 1 month, and maintains those levels throughout the 6-month course of therapy.*
- 92% of patients (n = 143) were symptom-free or had only mild symptoms following a 6-month course of therapy.
- Retreatment cannot be recommended since safety data for retreatment are not currently available.

*Pregnancy should be ruled out before therapy with SYNAREL is initiated, and patients should be advised to use a nonhormonal method of contraception when taking SYNAREL.
†There is a small loss in bone density with 6-month treatment, some of which may not be reversible. During one treatment period the bone loss should not be important. ‡Gonadotropin-releasing hormone analog. Please see brief summary of prescribing information on next page.

Control in the management of hypoestrogenic and therapeutic effects

- A small impact on bone,† as well as a predictable and manageable hypoestrogenic profile.
- Lets you terminate treatment immediately should that be required for any reason, unlike the depot form of GnRH‡ therapy.

BRIEF SUMMARY

SYNAREL® Nasal Solution contains nafarelin acetate (2 mg/mL, expressed as nafarelin base), benzalkonium chloride, glacial acetic acid, sodium hydroxide or hydrochloric acid, sorbitol, and purified water.

INDICATIONS AND USAGE: For management of endometriosis. Experience is limited to women 18 years and older treated for 6 months.

CONTRAINDICATIONS: Hypersensitivity to GnRH, GnRH agonist analogs or any excipients in SYNAREL; undiagnosed abnormal vaginal bleeding; pregnancy or possibility of pregnancy while taking the drug because SYNAREL may cause fetal harm when administered to a pregnant woman. If SYNAREL is used during pregnancy or if the patient becomes pregnant while taking this drug, she should be apprised of the potential hazard to the fetus; use in women who are breast feeding.

WARNINGS: Safe use in pregnancy has not been established clinically. Before starting treatment pregnancy must be excluded.

When used regularly at the recommended dose, SYNAREL usually inhibits ovulation and stops menstruation. Contraception is not insured, particularly if patients miss successive doses. Therefore, patients should use nonhormonal contraception. Advise patients to see their physician if they believe they may be pregnant. If a patient becomes pregnant during treatment, discontinue the drug; apprise patient of the potential risk to the fetus.

PRECAUTIONS General: Ovarian cysts have been reported in the first 2 months of therapy. These may resolve spontaneously or may require drug discontinuation or surgery.

Information for Patients: 1. Since menstruation should stop with SYNAREL, the patient should notify her physician if regular menstruation persists. If patient is compliant and menstruation persists to second month, consider doubling the dose. Counsel noncompliant patients on importance of taking SYNAREL regularly. 2. Patients should not use SYNAREL if pregnant, breast feeding, have undiagnosed abnormal vaginal bleeding, or are allergic to any of its ingredients. 3. Safe use in pregnancy has not been established. Therefore, a nonhormonal method of contraception should be used during treatment. If a patient becomes pregnant during treatment, she should discontinue the drug and consult her physician. 4. Adverse events occurring most frequently in clinical studies are associated with hypoestrogenism. Nasal irritation occurred in about 10% of patients. 5. Induced hypoestrogenic state results in a small loss in bone density over a 6-month treatment course. Some of this loss may not be reversible. During one six-month treatment period, this should not be important. In patients with major risk factors for decreased bone mineral content, i.e., chronic alcohol and/or tobacco use, strong family history of osteoporosis, or chronic use of drugs that can reduce bone mass such as anticonvulsants or corticosteroids, SYNAREL may pose additional risk. In these patients risks and benefits must be weighed carefully. Repeated courses of treatment with GnRH analogs are not advisable in patients with major risk factors for loss of bone mineral content. 6. Patients with intercurrent rhinitis should consult their physician for use of a topical nasal decongestant. If a topical nasal decongestant is required during treatment, it must be used at least 30 minutes after SYNAREL dosing to decrease the possibility of reducing drug absorption. 7. Retreatment cannot be recommended since safety data beyond 6 months are not available.

Drug Interactions: No pharmacokinetic-based drug-drug interaction studies have been conducted. Nafarelin acetate is a peptide primarily degraded by peptidase and not by cytochrome P-450 enzymes, and is only about 80% bound to plasma proteins at 4°C; therefore drug interactions would not be expected to occur.

Drug/Laboratory Test Interactions: SYNAREL in therapeutic doses suppresses the pituitary-gonadal system. Normal function is usually restored 4-8 weeks after treatment is discontinued. Therefore, diagnostic tests of pituitary gonadotropic and gonadal functions during treatment and up to 4-8 weeks after discontinuation of SYNAREL may be misleading.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Carcinogenicity studies were conducted in rats and mice at intramuscular doses up to 110 times and 560 times the maximum recommended human intranasal dose, respectively. These multiples of the human dose are based on the relative bioavailability of the drug by the two routes of administration. As with other GnRH agonists, nafarelin acetate given to laboratory rodents at high doses for prolonged periods induced hyperplasia and/or neoplasia of endocrine organs. At 24 months, there was an increase in the incidence of pituitary tumors (adenoma/carcinoma) in high-dose female rats and a dose-related increase in male rats. There was an increase in pancreatic islet cell adenomas in both sexes, and in benign testicular and ovarian tumors in the treated groups. There was a dose-related increase in benign adrenal medullary tumors in treated female rats. In mice, there was a dose-related increase in Harderian gland tumors in males and an increase in pituitary adenomas in high dose females. No metastases of these tumors were observed. It is known that tumorigenicity in rodents is particularly sensitive to hormonal stimulation.

Mutagenicity studies using bacterial, yeast, and mammalian systems provided no evidence of mutagenic potential.

Reproduction studies in male and female rats have shown full reversibility of fertility suppression when treatment was discontinued after continuous administration for up to 6 months.

Pregnancy, Teratogenic Effects: *Pregnancy Category X.* Intramuscular SYNAREL was administered to rats throughout gestation at about 0.5, 2, and 7 times the maximum recommended human intranasal dose based on the relative bioavailability by the two routes of administration. An increase in major fetal abnormalities was seen in 4/80 fetuses at the highest dose. A similar study at the same doses in rats and studies in mice and rabbits at doses up to 600 μg/kg/day and 0.18 μg/kg/day, respectively, failed to demonstrate an increase in fetal abnormalities after administration throughout gestation. In rats and rabbits, there was a dose-related increase in fetal mortality and a decrease in fetal weight with the highest dose.

Nursing Mothers: It is not known whether SYNAREL is excreted in human milk. Because many drugs are excreted in human milk, and because the effects of SYNAREL on lactation and/or the breastfed child have not been determined, SYNAREL should not be used by nursing mothers.

Pediatric Use: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS: The most frequently reported adverse reactions were those related to hypoestrogenism. In controlled studies comparing SYNAREL (400 μg/day) and danazol (600 or 800 mg/day), the following adverse reactions were most frequently reported and thought to be drug-related.

Hypoestrogenic: hot flashes (SYNAREL 90%, danazol 69%), decreased libido (22%, 7%), vaginal dryness (19%, 7%), headaches (19%, 21%), emotional lability (15%, 18%), insomnia (8%, 4%); **Androgenic:** acne (13%, 20%), myalgia (10%, 23%), reduced breast size (10%, 16%), edema (8%, 23%), seborrhea (8%, 17%), weight gain (8%, 28%), hirsutism (2%, 6%), increased libido (1%, 6%); **Local:** nasal irritation (10%, 3%); **Miscellaneous:** depression (2%, 5%), weight loss (1%, 3%).

Less than 1% of patients experienced paresthesia, palpitations, chloasma, maculopapular rash, eye pain, urticaria, asthenia, lactation, breast engorgement, and arthralgia. In clinical trials, immediate hypersensitivity thought to be possibly or probably related to nafarelin occurred in 3 (0.2%) of 1509 healthy subjects or patients.

Changes in Bone Density: After 6 months' treatment vertebral trabecular bone density and total vertebral bone mass, measured by quantitative computed tomography (QCT), decreased by an average of 8.7% and 4.3%, respectively, compared to pretreatment levels. There was partial recovery of bone density post-treatment; the average trabecular bone density and total bone mass were 4.9% and 3.3% less than pretreatment levels, respectively. Total vertebral bone mass measured by dual photon absorptiometry (DPA), decreased by a mean of 5.9% at end of treatment. Mean total vertebral mass, re-examined by DPA 6 months post-treatment, was 1.4% below pretreatment levels. There was little, if any, decrease in the mineral content in compact bone of the distal radius and second metacarpal. Use for longer than the recommended 6 months or in presence of other known risk factors for decreased bone mineral content may cause additional bone loss.

Changes in Laboratory Values: *Plasma enzymes.* During clinical trials SGOT and SGPT levels were more than twice the upper limit of normal in only one patient each. There was no other evidence of abnormal liver function and levels returned to normal after treatment was stopped.

Lipids. At enrollment and at end of treatment, 9% of patients on SYNAREL 400 μg/day and 2% on danazol had total cholesterol values above 250 mg/dL.

Of those with pretreatment cholesterol values below 250 mg/dL, 6% on SYNAREL and 18% on danazol had post-treatment values above 250 mg/dL.

Mean (± SEM) pretreatment values for total cholesterol from all patients were 191.8 (4.3) mg/dL in the SYNAREL group and 193.1 (4.6) mg/dL in the danazol group. At the end of treatment, mean values from all patients were 204.5 (4.8) mg/dL in the SYNAREL group and 207.7 (5.1) mg/dL in the danazol group. These increases from pretreatment values were significant ($p < 0.05$) in both groups.

Triglycerides were increased above the upper limit of 150 mg/dL in 12% of the patients on SYNAREL and in 7% of the patients on danazol.

At the end of treatment, no patients on SYNAREL had abnormally low HDL cholesterol fractions (< 30 mg/dL) compared with 43% of patients on danazol. No patients on SYNAREL had abnormally high LDL cholesterol fractions (> 190 mg/dL) compared with 15% of those on danazol. There was no increase in the LDL/HDL ratio in patients on SYNAREL, but approximately a 2-fold increase in the LDL/HDL ratio in patients on danazol.

Other changes. In comparative studies, the following changes were seen in approximately 10% to 15% of patients. SYNAREL was associated with elevations of plasma phosphorous and eosinophil counts, and decreases in serum calcium and WBC counts. Danazol therapy was associated with an increase of hematocrit and WBC.

OVERDOSAGE: At present there is no clinical evidence of adverse effects following overdosage of GnRH analogs.

New 2nd Edition!

COMPREHENSIVE GYNECOLOGY

Arthur L. Herbst, M.D.; Daniel R. Mishell, Jr., M.D.; Morton A. Stenchever, M.D.; and William Droegemueller, M.D.

The broad scope of this authoritative text covers the most recent advances in the field for residents and practitioners.

- Each chapter begins with a list of key terms and definitions and ends with a list of key points.
- Features increased coverage of perimenopausal and postmenopausal topics and improved coverage of dysfunctional uterine bleeding.

December 1991. Approx. 1,184 pages, 129 ills. (Book Code: 06244)

Also available: **COMPREHENSIVE GYNECOLOGY REVIEW, 2nd Edition** by Holzman, et al. A perfect supplement for Residents preparing for the boards.

December 1991. Approx. 320 pages, 123 ills. (Book Code: 02279)

CEFOTAN® IM/IV

(cefotetan disodium)

Available in 1-gram and 2-gram vials

For Intravenous or Intramuscular Use
PLEASE SEE FULL PRESCRIBING INFORMATION FOR A COMPLETE DESCRIPTION.
A BRIEF SUMMARY FOLLOWS.

INDICATIONS AND USAGE
TREATMENT

CEFOTAN is indicated for the therapeutic treatment of the following infections when caused by susceptible strains of the designated organisms:

Urinary Tract Infections caused by *E. coli, Klebsiella* species (including *K. pneumoniae*), *Proteus mirabilis,* and *Proteus* sp (which may include the organisms now called *Proteus vulgaris, Providencia rettgeri,* and *Morganella morganii*).

Lower Respiratory Tract Infections caused by *Streptococcus pneumoniae* (formerly *D. pneumoniae*), *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Haemophilus influenzae* (including ampicillin-resistant strains), *Klebsiella* species (including *K. pneumoniae*), *E. coli, Proteus mirabilis,* and *Serratia marcescens**.

Skin and Skin Structure Infections due to *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis, Streptococcus pyogenes, Streptococcus* species (excluding enterococci), *Escherichia coli, Klebsiella pneumoniae, Peptococcus niger**, *Peptostreptococcus* species.

Gynecologic Infections caused by *Staphylococcus aureus* (including penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis, Streptococcus* species (excluding enterococci), *Streptococcus agalactiae, E. coli, Proteus mirabilis, Neisseria gonorrhoeae,* Bacteroides species (excluding *B. distasonis, B. ovatus, B. thetaiotaomicron*), *Fusobacterium* species*, and gram-positive anaerobic cocci (including *Peptococcus niger* and *Peptostreptococcus* species).

Cefotetan, like other cephalosporins, has no activity against *Chlamydia trachomatis.* Therefore, when cephalosporins are used in the treatment of pelvic inflammatory disease, and *C. trachomatis* is one of the suspected pathogens, appropriate antichlamydial coverage should be added.

Intra-abdominal Infections caused by *E. coli, Klebsiella* species (including *K. pneumoniae*), *Streptococcus species* (excluding enterococci), *Bacteroides* species (excluding *B. distasonis, B. ovatus, B. thetaiotaomicron*) and *Clostridium* species*.

Bone and Joint Infections caused by *Staphylococcus aureus**.

*Efficacy for this organism in this organ system was studied in fewer than ten infections.

Specimens for bacteriological examination should be obtained in order to isolate and identify causative organisms and to determine their susceptibilities to cefotetan. Therapy may be instituted before results of susceptibility studies are known; however, once these results become available, the antibiotic treatment should be adjusted accordingly.

In cases of confirmed or suspected gram-positive or gram-negative sepsis or in patients with other serious infections in which the causative organism has not been identified, it is possible to use CEFOTAN concomitantly with an aminoglycoside. Cefotetan combinations with aminoglycosides have been shown to be synergistic *in vitro* against many Enterobacteriaceae and also some other gram-negative bacteria. The dosage recommended in the labeling of both antibiotics may be given and depends on the severity of the infection and the patient's condition.

NOTE: If CEFOTAN and an aminoglycoside are used concomitantly, renal function should be carefully monitored, especially if higher dosages of the aminoglycoside are to be administered or if therapy is prolonged, because of the potential nephrotoxicity and ototoxicity of aminoglycosidic antibiotics. Although, to date, nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

PROPHYLAXIS

The preoperative administration of CEFOTAN may reduce the incidence of certain postoperative infections in patients undergoing surgical procedures that are classified as clean contaminated or potentially contaminated (e.g., cesarean section, abdominal or vaginal hysterectomy, transurethral surgery, biliary tract surgery, and gastrointestinal surgery).

The prophylactic dose of CEFOTAN should be administered 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, CEFOTAN should be administered intravenously after the clamping of the umbilical cord.

If there are signs and symptoms of infection, specimens for culture should be obtained for identification of the causative organism so that appropriate therapeutic measures may be initiated.

CONTRAINDICATIONS

CEFOTAN is contraindicated in patients with known allergy to the cephalosporin group of antibiotics.

WARNINGS

BEFORE THERAPY WITH CEFOTAN IS INSTITUTED, CAREFUL INQUIRY SHOULD BE MADE TO DETERMINE WHETHER THE PATIENT HAS HAD PREVIOUS HYPERSENSITIVITY REACTIONS TO CEFOTETAN DISODIUM, CEPHALOSPORINS, PENICILLINS, OR OTHER DRUGS. IF THIS PRODUCT IS TO BE GIVEN TO PENICILLIN-SENSITIVE PATIENTS, CAUTION SHOULD BE EXERCISED BECAUSE CROSS-HYPERSENSITIVITY AMONG BETA-LACTAM ANTIBIOTICS HAS BEEN CLEARLY DOCUMENTED AND MAY OCCUR IN UP TO 10% OF PATIENTS WITH A HISTORY OF PENICILLIN ALLERGY. IF AN ALLERGIC REACTION TO CEFOTAN OCCURS, DISCONTINUE THE DRUG. SERIOUS ACUTE HYPERSENSITIVITY REACTIONS MAY REQUIRE TREATMENT WITH EPINEPHRINE AND OTHER EMERGENCY MEASURES, INCLUDING OXYGEN, INTRAVENOUS FLUIDS, INTRAVENOUS ANTIHISTAMINES, CORTICOSTEROIDS, PRESSOR AMINES AND AIRWAY MANAGEMENT, AS CLINICALLY INDICATED.

Pseudomembranous colitis has been reported with nearly all antibacterial agents, including cefotetan, and may range from mild to life-threatening. Onset of pseudomembranous colitis symptoms may occur during or after antibiotic treatment or surgical prophylaxis. Therefore, it is important to consider this diagnosis in patients who present with diarrhea subsequent to the administration of antibacterial agents.

Treatment with antibacterial agents alters the normal flora of the colon and may permit overgrowth of clostridia. Studies indicate that a toxin produced by *Clostridium difficile* is a primary cause of "antibiotic-associated colitis."

After the diagnosis of pseudomembranous colitis has been established, therapeutic measures should be initiated. Mild cases of pseudomembranous colitis usually respond to discontinuation of the drug alone. In moderate to severe cases, consideration should be given to management with fluids and electrolytes, protein supplementation, and treatment with an oral antibacterial drug effective against *Clostridium difficile.*

In common with many other broad-spectrum antibiotics, CEFOTAN may be associated with a fall in prothrombin activity and, possibly, subsequent bleeding. Those at increased risk include patients with renal or hepatobiliary impairment or poor nutritional state, the elderly, and patients with cancer. Prothrombin time should be monitored and exogenous vitamin K administered as indicated.

PRECAUTIONS

General: As with other broad-spectrum antibiotics, prolonged use of CEFOTAN may result in overgrowth of nonsusceptible organisms. Careful observation of the patient is essential. If superinfection does occur during therapy, appropriate measures should be taken.

CEFOTAN should be used with caution in individuals with a history of gastrointestinal disease, particularly colitis.

Information for Patients: As with some other cephalosporins, a disulfiram-like reaction characterized by flushing, sweating, headache, and tachycardia may occur when alcohol (beer, wine, etc.) is ingested within 72 hours after CEFOTAN administration. Patients should be cautioned about the ingestion of alcoholic beverages following the administration of CEFOTAN.

Drug Interactions: Although to date nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

Drug/Laboratory Test Interactions: The administration of CEFOTAN may result in a false-positive reaction for glucose in the urine using Clinitest®†, Benedict's solution, or Fehling's solution. It is recommended that glucose tests based on enzymatic glucose oxidase be used.

As with other cephalosporins, high concentrations of cefotetan may interfere with measurement of serum and urine creatinine levels by Jaffe reaction and produce false increases in the levels of creatinine reported.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Although long-term studies in animals have not been performed to evaluate carcinogenic potential, no mutagenic potential of cefotetan was found in standard laboratory tests.

Cefotetan has adverse effects on the testes of prepubertal rats. Subcutaneous administration of 500 mg/kg/day (approximately 8-16 times the usual adult human dose) on days 6-35 of life (thought to be developmentally analogous to late childhood and prepuberty in humans) resulted in reduced testicular weight and seminiferous tubule degeneration in 10 of 10 animals. Affected cells included spermatogonia and spermatocytes; Sertoli and Leydig cells were unaffected. Incidence and severity of lesions were dose-dependent; at 120 mg/kg/day (approximately 2-4 times the usual human dose) only 1 of 10 treated animals was affected, and the degree of degeneration was mild.

Similar lesions have been observed in experiments of comparable design with other methylthiotetrazole-containing antibiotics and impaired fertility has been reported, particularly at high dose levels. No testicular effects were observed in 7-week-old rats treated with up to 1000 mg/kg/day SC for 5 weeks, or in infant dogs (3 weeks old) that received up to 300 mg/kg/day IV for 5 weeks. The relevance of these findings to humans is unknown.

Pregnancy: Teratogenic Effects. Pregnancy Category B: Reproduction studies have been performed in rats and monkeys at doses up to 20 times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to cefotetan. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproductive studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Nursing Mothers: Cefotetan is excreted in human milk in very low concentrations. Caution should be exercised when cefotetan is administered to a nursing woman.

Pediatric Use: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS

In clinical studies, the following adverse effects were considered related to CEFOTAN therapy. Those appearing in italics have been reported during postmarketing experience.

Gastrointestinal symptoms occurred in 1.5% of patients; the most frequent were diarrhea (1 in 80) and nausea (1 in 700); *pseudomembranous colitis.* Onset of pseudomembranous colitis symptoms may occur during or after antibiotic treatment or surgical prophylaxis. (See WARNINGS.)

Hematologic laboratory abnormalities occurred in 1.4% of patients and included eosinophilia (1 in 200), positive direct Coombs' test (1 in 250), and thrombocytosis (1 in 300); *agranulocytosis, hemolytic anemia, leukopenia, thrombocytopenia,* and *prolonged prothrombin time.*

Hepatic enzyme elevations occurred in 1.2% of patients and included a rise in SGPT (1 in 150), SGOT (1 in 300), alkaline phosphatase (1 in 700), and LDH (1 in 700).

Hypersensitivity reactions were reported in 1.2% of patients and included rash (1 in 150) and itching (1 in 700); *anaphylactic reactions.*

Local effects were reported in less than 1.0% of patients and included phlebitis at the site of injection (1 in 300), and discomfort (1 in 500).

Miscellaneous: *Fever*

In addition to the adverse reactions listed above which have been observed in patients treated with cefotetan, the following adverse reactions and altered laboratory tests have been reported for cephalosporin-class antibiotics: urticaria, pruritis, Stevens-Johnson syndrome, erythema multiforme, toxic epidermal necrolysis, vomiting, abdominal pain, colitis, superinfection, vaginitis including vaginal candidiasis, renal dysfunction, toxic nephropathy, hepatic dysfunction including cholestasis, aplastic anemia, hemorrhage, increased BUN, increased creatinine, elevated bilirubin, pancytopenia, and neutropenia.

Several cephalosporins have been implicated in triggering seizures, particularly in patients with renal impairment when the dosage was not reduced (see DOSAGE AND ADMINISTRATION and OVERDOSAGE). If seizures associated with drug therapy occur, the drug should be discontinued. Anticonvulsant therapy can be given if clinically indicated.

DOSAGE AND ADMINISTRATION
TREATMENT

The usual adult dosage is 1 or 2 grams of CEFOTAN administered intravenously or intramuscularly every 12 hours for 5 to 10 days. Proper dosage and route of administration should be determined by the condition of the patient, severity of the infection, and susceptibility of the causative organism.

GENERAL GUIDELINES FOR DOSAGE OF CEFOTAN

Type of Infection	Daily Dose	Frequency and Route
Urinary Tract	1-4 grams	500 mg every 12 hours IV or IM 1 or 2 g every 24 hours IV or IM 1 or 2 g every 12 hours IV or IM
Skin & Skin Structure		
Mild-Moderate[a]	2 grams	2 g every 24 hours IV 1 g every 12 hours IV or IM
Severe	4 grams	2 g every 12 hours IV
Other Sites	2-4 grams	1 or 2 g every 12 hours IV or IM
Severe	4 grams	2 g every 12 hours IV
Life-Threatening	6 grams[b]	3 g every 12 hours IV

[a] *K. pneumoniae* skin and skin structure infections should be treated with 1 or 2 grams every 12 hours IV or IM.

[b] Maximum daily dosage should not exceed 6 grams.

If *C. trachomatis* is a suspected pathogen in gynecologic infections, appropriate antichlamydial coverage should be added, since cefotetan has no activity against this organism.

PROPHYLAXIS

To prevent postoperative infection in clean contaminated or potentially contaminated surgery in adults, the recommended dosage is 1 or 2 g of CEFOTAN administered once, intravenously, 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, the dose should be administered as soon as the umbilical cord is clamped.

IMPAIRED RENAL FUNCTION

When renal function is impaired, a reduced dosage schedule must be employed. See FULL PRESCRIBING INFORMATION for a complete description.

NOTE: Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration whenever solution and container permit.

Superficial laser vulvectomy. V. Surgical debulking is enhanced by adjuvant systemic interferon 815
Richard Reid, MD, Mitchell D. Greenberg, MD, David J. Pizzuti, MD, Katherine H. Omoto, MS, Lisa H. Rutledge, BA, and Whaijen Soo, MD, PhD
Detroit and Southfield, Michigan, and Nutley, New Jersey

In conjunction with surgical debulking by extended laser ablation, the use of adjuvant subcutaneous alpha interferon reduced the risk of early postoperative recurrence by about two thirds.

Therapeutic amniocentesis in the twin-twin transfusion syndrome appearing in the second trimester of pregnancy 820
N.J. Saunders, MD, R.J.M. Snijders, MSc, and K.H. Nicolaides, MD
London, England

Survival rate (37%) in 19 twin pregnancies with acute second-trimester polyhydramnios treated with amniocentesis was related to volume of amniotic fluid drained and intertwin disparity in size.

Immunohistochemical detection of the multi-drug-resistance marker P-glycoprotein in uterine cervical carcinomas and normal cervical tissue 825
José Schneider, PhD, Thomas Efferth, PhD, Jürgen Mattern, MD, Francisco-Javier Rodriguez-Escudero, PhD, and Manfred Volm, PhD
Bilbao, Spain, and Heidelberg, Germany

The multi-drug-resistance marker P-glycoprotein was detected by immunohistochemical examination in 10 of 11 uterine cervical carcinomas and all normal controls.

A randomized trial of prostaglandin E_2 in a controlled-release vaginal pessary for cervical ripening at term 830
Frank R. Witter, MD, Laura E. Rocco, MS, and Timothy R.B. Johnson, MD
Baltimore, Maryland

A new, controlled-release vaginal prostaglandin E_2 pessary has been shown to be efficacious for cervical ripening at term.

The resolution of chronic pelvic pain after normal laparoscopy findings 835
Philip N. Baker, DM, and E. Malcolm Symonds, MD
Nottingham, England

The symptoms of a majority of 60 patients with chronic pelvic pain resolved after laparoscopy without treatment.

Prostaglandin E_2 for induction of labor in patients with premature rupture of membranes at term 836
Deborah A. Ray, MD, and Thomas J. Garite, MD
Santa Clara and Orange, California

Prostaglandin E_2 can be used successfully to induce labor after premature rupture of membranes with lower maternal infectious morbidity and greater ease of administration, when compared with oxytocin.

Inviting all members of ACOG to
an interdisciplinary program

NEW PERSPECTIVES IN THE MANAGEMENT OF THE PREGNANT WOMAN WITH EPILEPSY

A Breakfast Symposium for Members of ACOG

Monday, April 27, and Tuesday, April 28

6:30–8:00 AM

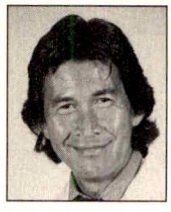
Registration and Breakfast beginning at 5:30 AM

Coliseum V
Caesar's Palace
Las Vegas, Nevada

Sponsored by the
Department of Continuing Education
in Health Sciences, UCLA Extension

Accreditation

As an organization accredited by ACCME to provide continuing medical education, the Department of Continuing Education in Health Sciences, UCLA Extension, certifies that this continuing medical education activity meets the criteria for 1.5 hours in Category I of the Physician's Recognition Award of the American Medical Association and the California Medical Association Certificate in Continuing Medical Education.



Registration

All members of the American College of Obstetricians and Gynecologists will receive an invitation and registration form by mail. Please complete and return that form as soon as possible. Space is limited and registrations will be accepted on a first-come, first-served basis. If, however, you do not preregister, you are welcome to do so immediately before the meeting on either Monday, April 27, or Tuesday, April 28.

Acknowledgment

This symposium is made possible through an educational grant from Parke-Davis, Division of Warner-Lambert Company.

The cavitational ultrasonic surgical aspirator for cytoreduction in advanced ovarian cancer 843

Peter G. Rose, MD

Worcester, Massachusetts

Over a 24-month period the cavitational ultrasonic surgical aspirator was used for cytoreduction in 48% of patients with advanced ovarian cancer.

Does oxytocin augmentation increase perinatal risk in primigravid labor? 847

David J. Cahill, MB, Peter C. Boylan, MAO, and Colm O'Herlihy, MD

Dublin, Ireland

Oxytocin augmentation of spontaneous labor in 14,119 nulliparous women did not increase the incidence of asphyxial perinatal death or neurologic abnormality among their infants.

The frequency of breech presentation by gestational age at birth: A large population-based study 851

Durlin E. Hickok, MD, MPH, Diane C. Gordon, MS, MPH, John A. Milberg, MPH, Michelle A. Williams, ScD, and Janet R. Daling, PhD

Seattle, Washington

Breech presentation was found to be less frequent at each gestational age from a study of birth records, when compared with prior studies that used antenatal ultrasonography.

Ovarian carcinoma of low malignant potential, infertility, and induction of ovulation—Is there a link? 853

Gary L. Goldberg, MD, and Carolyn D. Runowicz, MD

Bronx, New York

We report three cases of ovarian carcinoma of low malignant potential associated with infertility and ovulation induction in patients <35 years old.

Maternal and fetal cardiovascular responses to strenuous bicycle exercise 854

Marieke B. van Doorn, MD, Fred K. Lotgering, MD, PhD, Piet C. Struijk, BSc, Jan Pool, MD, PhD, and Henk C.S. Wallenburg, MD, PhD

Rotterdam, The Netherlands

Pregnancy does not markedly modulate the maternal electrocardiogram or blood pressure response to strenous bicycle exercise; prior exercise does not markedly affect fetal heart rate.

Is trichomoniasis often associated with bacterial vaginosis in pregnant adolescents? 859

Janine A. James, MD, Jessica L. Thomason, MD, Sheldon M. Gelbart, PhD, Peter Osypowski, MT(ASCP), Paul Kaiser, RN, CNM, and Lisa Hanson, RN, CNM

Milwaukee, Wisconsin

Pregnant adolescents with *Trichomonas vaginalis* often have signs and symptoms of bacterial vaginosis, but the two conditions can be differentiated.

Laparoscopic radical hysterectomy with paraaortic and pelvic node dissection 864

Camran R. Nezhat, MD, Matthew O. Burrell, MD, Farr R. Nezhat, MD, Benedict B. Benigno, MD, and Charles E. Welander, MD

Macon and Atlanta, Georgia

Laparoscopic radical hysterectomy and paraaortic and pelvic lymphadenectomy are reported.

Emergency room use of transvaginal ultrasonography by obstetrics and gynecology residents 866

Ilan Timor-Tritsch, MD, Susan Greenidge, MD, Dahlia Admon, MD, and M. Lynne Reuss, MD

New York, New York

The emergency use of transvaginal ultrasonography by obstetrics and gynecology residents shortened the time to establish a diagnosis in patients seen in the emergency room.

Ultrasonographic dating of pregnancy causes significant errors in Down syndrome risk assessment that may be minimized by use of biparietal diameter–based means 872

Timothy M. Reynolds, MB, ChB, Michael D. Penney, MD, and Howard Hughes, MSc

Cardiff and Newport, Wales

If ultrasonographically derived gestational week is used to define multiples of the median for Down syndrome risk assessment, the calculated risks may be incorrect.

Infarction of the uterus from subacute incomplete inversion 878

Mary S. Romo, MD, David A. Grimes, MD, and Philip O. Strassle, MD

Los Angeles, California

Intravenous administration of sodium fluorescein dye confirmed the intraoperative diagnosis of necrosis of the uterus, which led to the decision for hysterectomy.

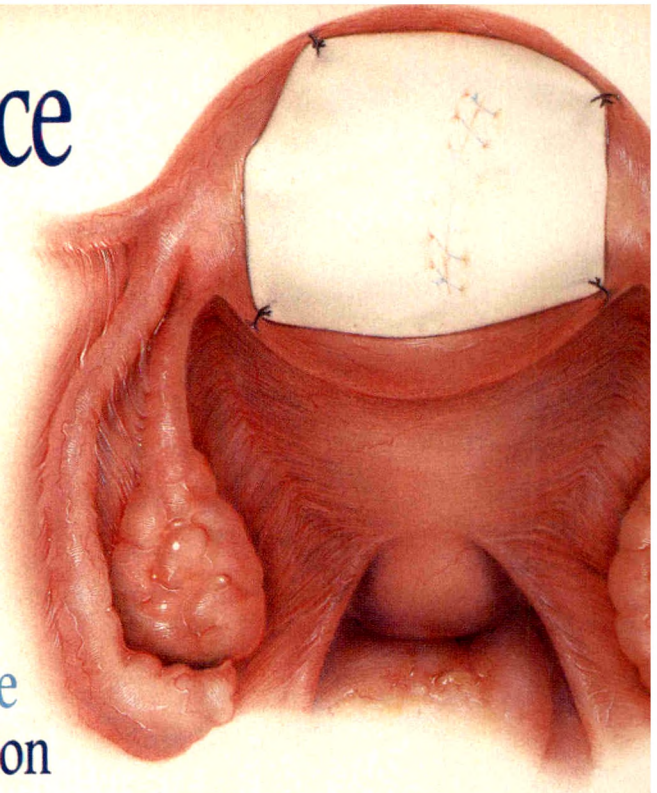
The primary application of three-dimensional ultrasonography in obstetrics 880

Hong-Chang Kuo, MD, Fong-Ming Chang, MD, Chun-Hsein Wu, MD, Bor-Lin Yao, MD, and Chi-Hong Liu, MD

Tainan, Taiwan

We suggest that three-dimensional ultrasonography provides more information for clinical diagnosis and understanding of the fetal anatomy than conventional two-dimensional ultrasonography has done.

Cellular immunity of patients with recurrent or refractory vulvovaginal moniliasis 887



Ignatius W. Fong, MD, Paul McCleary, MD, and Stanley Read, MD

Toronto, Ontario, Canada

Cellular immunity was studied in 73 patients with recurrent vaginal moniliasis and 37 healthy control subjects; most patients were found to have normal cellular immunity.

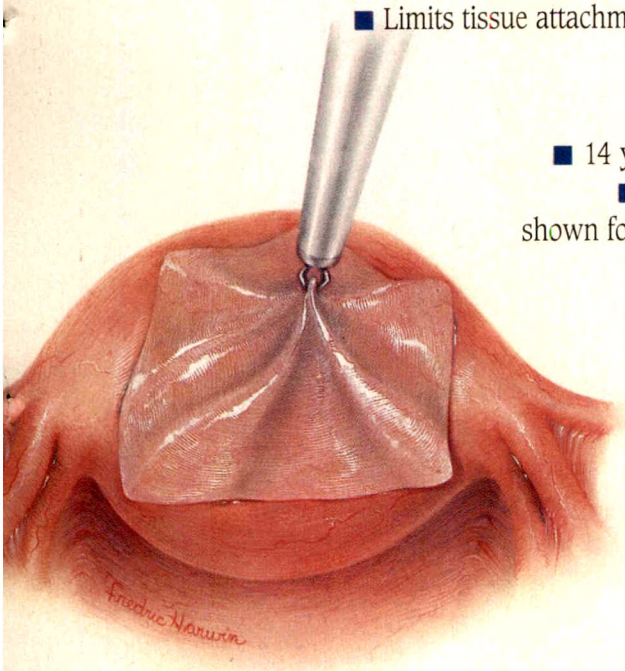
Invariant Performance in Peritoneal Reconstruction of Myomectomy Sites



...The GORE-TEX® Surgical Membrane
The Choice in Peritoneal Reconstruction

Incision sites for myomectomy can be a significant post-operative problem. Hemostatically difficult to control, they demand an adjuvant unaffected by the biological processes that occur following deperitonealization...The GORE-TEX Surgical Membrane.

Performance by Design

- Composed of the inert biomaterial, expanded polytetrafluoroethylene (e-PTFE)
- Limits tissue attachment with an extremely small pore size

Proven and Established

- Long record of safety and effectiveness
- 14 years of reliability demonstrated among cardiac surgeons
- Safety substantiated and invariant performance shown for myomectomy site protection in a multi-center clinical study

Convenient

- Configured for Peritoneal Reconstruction
- Packaged sterile and **can be resterilized**

To receive further information on the GORE-TEX Surgical Membrane or to consult an application specialist, call **1-800-437-8181**. For orders and overnight delivery, 24 hours a day, please call **1-800-528-8763**.

Validity of postnatal assessments of gestational age: A comparison of the method of Ballard et al. and early ultrasonography 891
Greg R. Alexander, MPH, ScD, Francois de Caunes, MD, MPH, Thomas C. Hulsey, MSPH, ScD, Mark E. Tompkins, PhD, and Marilee Allen, MD
Minneapolis, Minnesota, Guadeloupe, French West Indies, Charleston and Columbia, South Carolina, and Baltimore, Maryland

This study investigates the accuracy of postnatal gestational age assessments to predict preterm, term, postterm, and small-for-gestational-age infants with early ultrasonography used as the gold standard.

Diagnosis of cervical change in pregnancy by means of transvaginal ultrasonography 896
Gary M. Joffe, MD, Gerardo O. Del Valle, MD, Luis A. Izquierdo, MD, George J. Gilson, MD, James F. Smith, MD, Molly S. Chatterjee, MD, and Luis B. Curet, MD
Albuquerque, New Mexico

Endovaginal ultrasonographic assessment of the cervix may provide an objective basis for the diagnosis of cervical incompetence.

Contraceptive compliance with a levonorgestrel triphasic and a norethindrone monophasic oral contraceptive in adolescent patients 901
Elizabeth R. Woods, MD, MPH, Estherann Grace, MD, Kathryn Klein Havens, MD, James L. Merola, PhD, and S. Jean Emans, MD
Boston, Massachusetts

Contraceptive compliance for a levonorgestrel triphasic pill was compared with that for a norethindrone monophasic pill in adolescent patients at a clinic and in a private practice.

Prenatal ultrasonographic diagnosis of fetal scrotal inguinal hernia 907
Israel Meizner, MD, Arie Levy, MD, Miriam Katz, MD, Tzippi Simhon, and Marek Glezerman, MD
Beer-Sheva, Israel

A rare case of in utero ultrasonographic diagnosis of fetal scrotal inguinal hernia is presented.

Uterine and umbilical flow velocity waveforms in normotensive and hypertensive subjects during the angiotensin II sensitivity test 910
Risto U. Erkkola, MD, PhD, and Jouko P. Pirhonen, MD
Turku, Finland

The increase in the systolic/diastolic ratio in the uterine artery as a result of angiotensin II was similar in normotensive and hypertensive subjects, yet the recovery was slower in hypertensive ones.

Patterns of failure of bulky-barrel carcinomas of the cervix 916
Deborah L. Coleman, MD, Donald G. Gallup, MD, Hugh D. Wolcott, MD, Luther B. Otken, MD, and Richard J. Stock, MD
Augusta, Georgia, and Portsmouth, Virginia

An analysis of patients with bulky-barrel cervical lesions indicates recurrences are frequently outside the pelvis, and adjunctive chemotherapy may be beneficial to some patients who have hysterectomy after irradiation.

Contents

Normal fetal Doppler inferior vena cava, transtricuspid, and umbilical artery flow velocity waveforms between 11 and 16 weeks' gestation 921
Juriy W. Wladimiroff, MD, PhD, Tjeerd W.A. Huisman, MD, Patricia A. Stewart, PhD, and Th. Stijnen, PhD
Rotterdam, The Netherlands

At 11 to 16 weeks' gestation there is a reduction in fetal inferior vena cava retrograde flow that may be determined by rising cardiac compliance or ventricular relaxation rate.

Maternal glucose intolerance and the subcutaneous terbutaline pump 925
Connie Lindenbaum, MD, Jack Ludmir, MD, Frann B. Teplick, MSN, RNC, Arnold W. Cohen, MD, and Philip Samuels, MD
Philadelphia, Pennsylvania

Use of the subcutaneous terbutaline pump in the treatment of premature labor does not appear to increase the incidence of maternal glucose intolerance.

Hydrops fetalis associated with congenital myotonic dystrophy 929
Ashraf M. Afifi, MD, Asha Rijhsinghani Bhatia, MD, and Fabian Eyal, MD
Baltimore, Maryland

A case report of hydrops fetalis associated with congenital muscular dystrophy is presented; congenital muscular dystrophy can be associated with fetal hydrops and should be included among the various causes of nonimmune hydrops fetalis.

Vaginal injury resulting from sliding down a water chute 930
Jacob Niv, MD, Joseph B. Lessing, MD, Joseph Hartuv, MD, and M. Reuben Peyser, MD
Tel Aviv, Israel

This article provides a description of a woman who sustained a vaginal laceration after sliding down a water chute while using a vaginal tampon; the potential mechanism is discussed.

Fetal urine biochemistry in the assessment of obstructive uropathy 932
K.H. Nicolaides, MD, H.H. Cheng, MD, R.J.M. Snijders, MSc, and C.F. Moniz, MD
London, England

In 60 fetuses with obstructive uropathy the best predictors of renal function were the urinary concentrations of calcium and/or sodium.

Characteristics of three vaginal flora patterns assessed by Gram stain among pregnant women 938
Sharon L. Hillier, PhD, Marijane A. Krohn, PhD, Robert P. Nugent, PhD, and Ronald S. Gibbs, MD, for the Vaginal Infections and Prematurity Study Group
Seattle, Washington, Bethesda, Maryland, and Denver, Colorado

There are three vaginal flora patterns in pregnant women associated with different clinical and microbiologic characteristics.

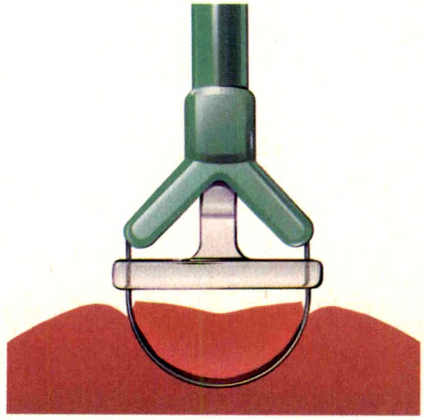
The Perfect Loop Excision Requires FINESSE™



The integrated system that provides smooth, precise loop excisions and efficient removal of odors and harmful particles.

By now you know that loop therapy is a safer and more efficient means of treating CIN and other dysplasias. But how important is the equipment you buy to perform Loop Excision of the Transformation Zone (LETZ)?

We think it's very important. That's why we've designed FINESSE™.

FINESSE combines the generator and smoke evacuator so it's easier to operate than other equipment. But more importantly, our controlled output circuitry delivers the precise power necessary for optimum cutting quality while eliminating the risk of thermal tissue damage.

FINESSE eliminates thermal damage with its controlled output circuitry. This means, unlike other ESUs, FINESSE delivers the proper power at initial contact, maximum depth and at the end of the excision—giving you a better histological specimen for examination.

As a leading manufacturer in loop electrosurgery technology, Utah Medical also provides a complete line of disposable loops as well as our procedure tray of disposables—LETZ SET™. Working together they're part of the FINESSE System. A system that's the perfect solution for your office.

Call our Customer Service Representative today to arrange a free demonstration. You'll see why the perfect excision requires FINESSE™.

Preterm premature rupture of membranes: Results of expectant management in patients with cervical cultures positive for group B streptococcus or *Neisseria gonorrhoeae* 945

George Larry Maxwell, MD, and William J. Watson, MD

Chapel Hill, North Carolina

In patients with preterm premature rupture of membranes and a positive cervical culture who are treated with prophylactic antibiotics, there is an increased risk of neonatal pneumonia.

Comparison of transdermal and oral estrogen-progestin replacement therapy: Effects on serum lipids and lipoproteins 950

David Crook, PhD, Michael P. Cust, MB, Kevin F. Gangar, MB, Melek Worthington, MSc, Timothy C. Hillard, BM, John C. Stevenson, MB, Malcolm I. Whitehead, MB, and Victor Wynn, MD

London, England

Transdermal administration of postmenopausal estrogen-progestin alters plasma lipoprotein risk factors for cardiovascular disease.

Oral contraceptive type and functional ovarian cysts 956

Stephan F. Lanes, PhD, Brenda Birmann, BA, Alexander M. Walker, MD, DrPH, and Suanne Singer, BA

Chestnut Hill and Boston, Massachusetts, and Augusta, Maine

The preventive effect of oral contraceptives on symptomatic functional ovarian cysts is greater for monophasic pills—especially high-dose pills—than for multiphasic pills.

Plasma endothelin levels in preeclampsia: Elevation and correlation with uric acid levels and renal impairment 962

Barbara A. Clark, MD, Lisa Halvorson, MD, Benjamin Sachs, MD, and Franklin H. Epstein, MD

Boston, Massachusetts

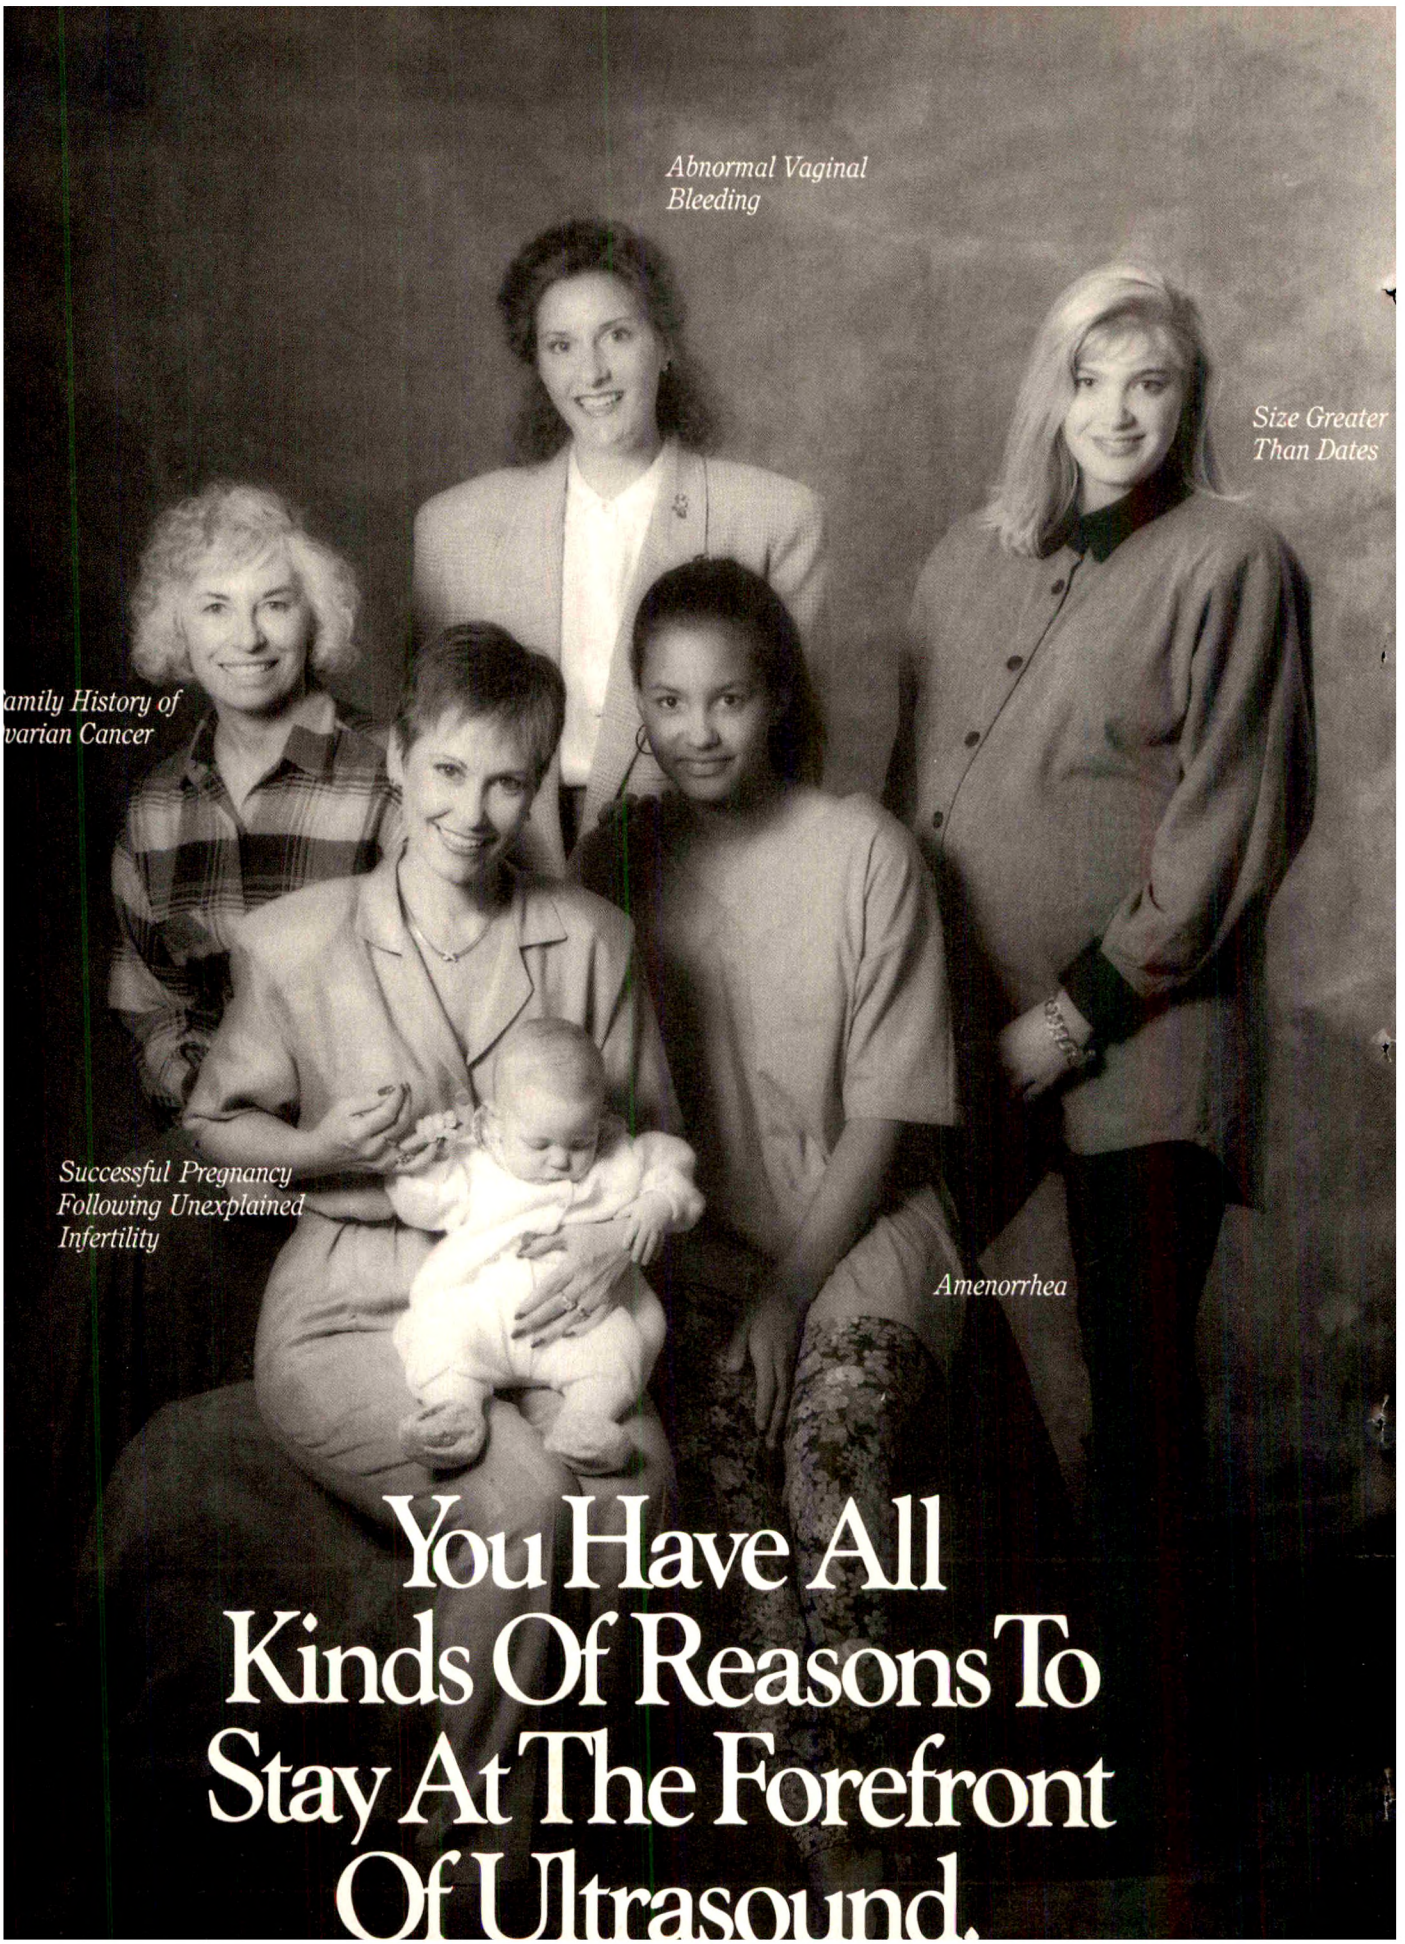
Plasma endothelin levels were elevated in women with preeclampsia as compared with normal pregnant and nonpregnant women and correlated closely with markers of disease severity.

Latex anaphylaxis in an obstetrics and gynecology physician 968

M. Dwight Chen, MD, Jeffrey S. Greenspoon, MD, and Toni L. Long, MD

Los Angeles, California

Latex anaphylaxis caused by surgical gloves occurred during an obstetric emergency and necessitated treatment of the physician.



Does amniotic fluid analysis reflect acid-base balance in fetal blood? 970

D.L. Economides, MD, P. Johnson, MA, and I.Z. MacKenzie, MD

Oxford, England

Sampling of human fetal umbilical blood and amniotic fluid in normal and red blood cell isoimmunized pregnancies failed to show significant correlations in acid-base values except between amniotic fluid and umbilical venous P_{CO_2}.

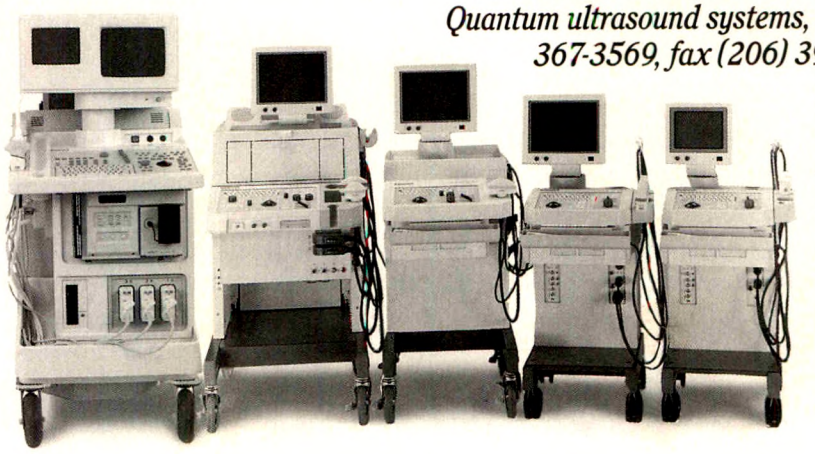
You Have All Kinds Of Reasons To Stay At The Forefront Of Ultrasound.

We Have The Technology To Keep You There.



In offices, clinics and hospitals worldwide, Siemens Quantum is changing the way doctors look at their patients.

Our imaging systems and state-of-the-art diagnostics are pushing the limits of ultrasound. Providing more and better information at every level. Performing more types of obstetric and gynecologic studies than ever before.

The Siemens Quantum alliance joins two powerful forces: Siemens, the world's largest medical imaging company, and Quantum, a pioneer and technological leader in ultrasound.

Together, we're committed to maintaining our leading edge. Which means keeping our systems—and our customers—at the forefront of diagnostic imaging.

The Siemens SONOLINE® SI-200 & 250 are versatile, affordable, compact and easy to use.

And they come with the most advanced, multi-frequency, patient-friendly endovaginal probe on the market.

The Siemens SONOLINE® SI-450 offers superb image quality and a comprehensive set of reports and measurement packages. For complete transabdominal, endovaginal and spectral Doppler capabilities, there's no better equipment for the price.

The Quantum 2000 is a high-performance, high-end, all-purpose system that's unsurpassed for high-definition gray scale and ultra-sensitive color flow. Its advanced technology lets you see subtle differences in tissue, accurately image the tiniest flows, and detect even the smallest details at depth.

To receive more information on Siemens Quantum ultrasound systems, call 1-800-367-3569, fax (206) 391-9161, or write us at 1040 12th Ave. N.W., Issaquah, WA 98027.

The clinical significance of thrombocytosis in women presenting with a pelvic mass 974
Eva Chalas, MD, Marie Welshinger, MD, William Engellener, MD, John Chumas, MD, Robert Barbieri, MD, and William J. Mann, MD
Stony Brook, New York

Preoperative thrombocytosis (platelet count >400,000/μl), in addition to an elevated serum CA 125 level, has a high positive predictive value (95%) for gynecologic malignancy in patients presenting with a pelvic mass.

Unexplained elevated maternal serum α-fetoprotein is not predictive of adverse perinatal outcome in an indigent urban population 978
Owen P. Phillips, MD, Joe Leigh Simpson, MD, Cynthia D. Morgan, RNC, MS, Richard N. Andersen, PhD, Lee P. Shulman, MD, Carole M. Meyers, MD, Baha Sibai, MD, David C. Shaver, MD, Elizabeth A. Tolley, PhD, and Sherman Elias, MD
Memphis, Tennessee

In an obstetric population already identified as high risk, an unexplained elevated maternal serum α-fetoprotein level does not appear to offer additional predictive value for adverse perinatal outcome.

Pelvic inflammatory disease: Trends in hospitalizations and office visits, 1979 through 1988 983
Robert T. Rolfs, MD, Edward I. Galaid, MD, MPH, and Akbar A. Zaidi, MS
Atlanta, Georgia

From 1979 to 1988 in the United States, hospitalizations for acute pelvic inflammatory disease decreased by 36% while office visits remained stable.

BASIC SCIENCE SECTION

Mimicking low amniotic pressure by chronic pharyngeal drainage does not impair lung development in fetal sheep 991
Nicholas M. Fisk, MB, Michael J. Parkes, DPhil, Peter J. Moore, PhD, Mark A. Hanson, DPhil, Jonathan Wigglesworth, MD, and Charles H. Rodeck, DSc
Reading and London, England

In sheep, mimicking the reduced amniotic pressure found in oligohydramnios without altering amniotic fluid volume did not impair fetal lung growth.

Stimulation of ovarian tumor cell proliferation with monocyte products including interleukin-1, interleukin-6, and tumor necrosis factor-α 997
Shu Wu, MD, Kerry Rodabaugh, MD, Otoniel Martinez-Maza, PhD, Joanna M. Watson, PhD, David S. Silberstein, MD, Cinda M. Boyer, PhD, William P. Peters, MD, J. Brice Weinberg, MD, Jonathan S. Berek, MD, and Robert C. Bast, Jr., MD
Durham, North Carolina, Los Angeles, California, and Boston, Massachusetts

Growth of ovarian tumor cells could be stimulated by monocyte products including interleukin-1, interleukin-6, and tumor necrosis factor-α.

Effects of chronic maternal anemia on systemic and uteroplacental oxygenation in near-term pregnant sheep 1007

Ellen Herget Delpapa, MD, Daniel I. Edelstone, MD, J. Ross Milley, MD, and Michael Balsan, MD
Pittsburgh, Pennsylvania

Maternal anemia of 6 days' duration leads to increases in both tissue perfusion and oxygen extraction, ensuring that maternal tissues receive adequate oxygen supplies.

Analysis of peripheral blood of pregnant women for the presence of fetal Y chromosome–specific ZFY gene deoxyribonucleic acid sequences 1013

Shu-Min Kao, BS, Gu-Ching Tang, MS, T'sang-T'ang Hsieh, MD, Kung-Chia Young, MS, Han-Chow Wang, MD, and Chia C. Pao, PhD
Taipei and Tainan, Taiwan

Deoxyribonucleic acid sequences of ZFY (zinc-finger-Y) gene on human Y chromosomes were detected in peripheral blood of pregnant women who bore male fetuses by an in vitro enzymatic deoxyribonucleic acid amplification method.

Make researching easier with the Ten-Year Cumulative Index (1978-1987) to the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY

The Ten-Year Cumulative Index is a complete guide to more than 30,000 pages of original articles, case reports, letters, and editorials published in the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY from 1978 through 1987 (volumes 130 to 157). Numbering more than 800 pages, the Cumulative Index includes both a subject and an author index. This hard-cover volume is $64.50 ($69.00 international). Prices include shipping. *Payment must accompany all orders and must be in U.S. funds, drawn on a U.S. bank.*

Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318 USA; phone (314) 453-4394. In the U.S., call toll-free: 1-800-325-4177, ext. 4394. Please allow six weeks for delivery.

The JOURNAL is abstracted and/or indexed in *Index Medicus, Science Citation Index, Current Contents/Clinical Medicine, Current Contents/Life Sciences, Excerpta Medica, BRS Colleague,* and MEDLINE.

Authorization to photocopy items for internal or personal use is granted by Mosby–Year Book, Inc., for libraries and other users registered with the Copyright Clearance Center (CCC) Transactional Reporting Service, provided that 10¢ per page per copy is paid directly to CCC, 27 Congress St., Salem, MA 01970; phone (508)744-3350. You think it's good medicine.

She thinks it's wonderful.

Thanks to you and Premarin®, she could make these years the best years of her life

Hot flashes–Now part of the past for millions of women

Premarin® can dramatically reduce the incidence of hot flashes, night sweats, and related sleep disturbances.

Osteoporosis–No longer part of the future for many women

Premarin® is the first estrogen product proven to prevent postmenopausal osteoporosis in women at risk. And it's the *only* estrogen product proven in studies to reduce the risk of osteoporosis-related fractures by as much as 62%.[1]

Contraindications

Estrogens should not be used in women (or men) with any of the following conditions: known or suspected 1) pregnancy, 2) breast cancer, 3) estrogen-dependent neoplasia, 4) undiagnosed abnormal genital bleeding, 5) active thrombophlebitis or thromboembolic disorders.

Note: Estrogens have been reported to increase the risk of endometrial carcinoma in postmenopausal women.

Nothing else is

PREMARIN®

(conjugated estrogens tablets)

The appearance of this tablet is a trademark of Wyeth-Ayerst Laboratories.

Please see brief summary of prescribing information on last page of this advertisement.

BRIEF SUMMARY *(FOR FULL PRESCRIBING INFORMATION AND PATIENT INFORMATION, SEE PACKAGE CIRCULARS.)*

PREMARIN® Brand of conjugated estrogens tablets, USP
PREMARIN® Brand of conjugated estrogens Vaginal Cream, in a nonliquefying base

1. ESTROGENS HAVE BEEN REPORTED TO INCREASE THE RISK OF ENDOMETRIAL CARCINOMA. Close clinical surveillance of all women taking estrogens is important. Adequate diagnostic measures including endometrial sampling when indicated should be undertaken to rule out malignancy in all cases of undiagnosed persistent or recurring abnormal vaginal bleeding. There is currently no evidence that "natural" estrogens are more or less hazardous than "synthetic" estrogens at equiestrogenic doses.
2. ESTROGENS SHOULD NOT BE USED DURING PREGNANCY.
Estrogen therapy during pregnancy is associated with an increased risk of congenital defects in the reproductive organs of the male and female fetus, an increased risk of vaginal adenosis, squamous-cell dysplasia of the uterine cervix, and vaginal cancer in the female later in life. The 1985 DES Task Force concluded that women who used DES during their pregnancies may subsequently experience an increased risk of breast cancer. However, a causal relationship is still unproven, and the observed level of risk is similar to that for a number of other breast cancer risk factors.
There is no indication for estrogen therapy during pregnancy. Estrogens are ineffective for the prevention or treatment of threatened or habitual abortion.

DESCRIPTION: PREMARIN (conjugated estrogens, USP) contains a mixture of estrogens, obtained exclusively from natural sources, blended to represent the average composition of material derived from pregnant mares' urine. It contains estrone, equilin, and 17α-dihydroequilin, together with smaller amounts of 17α-estradiol, equilenin, and 17α-dihydroequilenin as salts of their sulfate esters. Tablets are available in 0.3 mg, 0.625 mg, 0.9 mg, 1.25 mg, and 2.5 mg strengths of conjugated estrogens. Cream is available as 0.625 mg conjugated estrogens per gram.

INDICATIONS AND USAGE: Moderate-to-severe vasomotor symptoms associated with the menopause. (There is no evidence that estrogens are effective for nervous symptoms or depression which might occur during menopause and they should not be used to treat these conditions.) Prevention and management of osteoporosis (abnormally low bone mass). Atrophic vaginitis. Atrophic urethritis. Hypoestrogenism due to hypogonadism, castration or primary ovarian failure.

PREMARIN (conjugated estrogens) Vaginal Cream is indicated in the treatment of atrophic vaginitis and kraurosis vulvae.

PREMARIN HAS NOT BEEN SHOWN TO BE EFFECTIVE FOR ANY PURPOSE DURING PREGNANCY AND ITS USE MAY CAUSE SEVERE HARM TO THE FETUS (SEE BOXED WARNING).

CONTRAINDICATIONS: Estrogens should not be used in women (or men) with any of the following conditions: 1. Known or suspected pregnancy (see Boxed Warning). 2. Known or suspected cancer of the breast except in appropriately selected patients being treated for metastatic disease. 3. Known or suspected estrogen-dependent neoplasia. 4. Undiagnosed abnormal genital bleeding. 5. Active thrombophlebitis or thromboembolic disorders. 6. Estrogen replacement therapy has not been reported to increase the risk of thrombophlebitis and/or thromboembolic disease. However, there is insufficient information regarding women who have had previous thromboembolic disease.

PREMARIN Tablets and Vaginal Cream should not be used in patients hypersensitive to their ingredients.

WARNINGS: Some studies suggest a possible increased incidence of breast cancer in women taking higher doses of estrogen for prolonged time periods. The majority of studies have not shown an association with usual estrogen replacement doses. Endometrial cancer risk among estrogen users was about 4-fold or greater than in non-users, and appears dependent on treatment duration and estrogen dose. In patients on combined estrogen-progestin therapy, this risk appears to be decreased. (See PRECAUTIONS below.)

Estrogen therapy during pregnancy is associated with an increased risk of fetal congenital reproductive tract disorders.

A 2.5-fold increase in the risk of surgically confirmed gall bladder disease in women receiving postmenopausal estrogens has been reported.

Large doses of estrogen such as those used to treat prostate and breast cancer have been shown to increase the risk of non-fatal myocardial infarction, pulmonary embolism, and thrombophlebitis in men. This cannot necessarily be extrapolated to women. However, to avoid theoretical cardiovascular risk caused by high estrogen doses, the doses for estrogen replacement therapy should not exceed the recommended dose.

Blood pressure should be monitored with estrogen use, especially if high doses are used.

Estrogens may lead to severe hypercalcemia in patients with breast cancer and bone metastases.

PRECAUTIONS: The addition of a progestin for 7 or more days of a cycle of estrogen administration reportedly lowers the incidence of endometrial hyperplasia. Studies of endometrium suggest that 10 to 13 days of progestin are needed to provide maximal endometrial maturation and elimination of hyperplastic changes. Additional risks, such as adverse effects on carbohydrate and lipid metabolism, may be associated with the inclusion of progestin in estrogen replacement regimens. The choice of progestin and dosage may be important in minimizing these adverse effects.

Physical examination and a complete medical and family history should be taken prior to the initiation of any estrogen therapy with special reference to blood pressure, breasts, abdomen, and pelvic organs, and should include a Papanicolaou smear. As a general rule, estrogen should not be prescribed for longer than one year without another physical examination being performed. Conditions influenced by fluid retention, such as asthma, epilepsy, migraine, and cardiac or renal dysfunction, require careful observation. Certain patients may develop manifestations of excessive estrogenic stimulation, such as abnormal or excessive uterine bleeding and mastodynia. Pre-existing uterine leiomyomata may increase in size during estrogen use. Estrogens should be used with care in patients with impaired liver function, renal insufficiency, or metabolic bone diseases associated with hypercalcemia.

The following drug/laboratory test interactions have been reported, some only with estrogen-progestin combinations (oral contraceptives):

1. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3; increased norepinephrine-induced platelet aggregability.
2. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by T_4 levels determined by column or by radioimmunoassay. Free T_3 resin uptake is decreased, reflecting the elevated TBG; free T_4 concentration is unaltered.
3. Impaired glucose tolerance.
4. Reduced response to metyrapone test.
5. Reduced serum folate concentration.

MUTAGENESIS AND CARCINOGENESIS: Long-term, continuous administration of natural and synthetic estrogens in certain animal species increases the frequency of carcinomas of the breast, cervix, vagina, and liver.

PREGNANCY CATEGORY X: Estrogens should not be used during pregnancy. See **CONTRAINDICATIONS** and Boxed Warning.

NURSING MOTHERS: As a general principle, the administration of any drug to nursing mothers should be done only when clearly necessary since many drugs are excreted in human milk.

ADVERSE REACTIONS: The following have been reported with estrogenic therapy: changes in vaginal bleeding pattern and abnormal withdrawal bleeding or flow, breakthrough bleeding, spotting, increase in size of uterine fibromyomata, vaginal candidiasis, change in amount of cervical secretion; tenderness or enlargement of breasts; nausea, vomiting, abdominal cramps, bloating, cholestatic jaundice; chloasma or melasma that may persist when drug is discontinued, erythema multiforme, erythema nodosum, hemorrhagic eruption, loss of scalp hair, hirsutism; steepening of corneal curvature, intolerance to contact lenses; headache, migraine, dizziness, mental depression, chorea; increase or decrease in weight; reduced carbohydrate tolerance; aggravation of porphyria; edema; changes in libido.

ACUTE OVERDOSAGE: May cause nausea and vomiting.

DOSAGE AND ADMINISTRATION:

PREMARIN® Brand of conjugated estrogens tablets, USP

1. *Given cyclically for short-term use only.* For treatment of moderate-to-severe vasomotor symptoms, atrophic vaginitis, or atrophic urethritis associated with the menopause (0.3 mg to 1.25 mg or more daily). The lowest dose that will control symptoms should be chosen and medication should be discontinued as promptly as possible. Administration should be cyclic (eg, three weeks on and one week off). Attempts to discontinue or taper medication should be made at three- to six-month intervals.
2. *Given cyclically:* Hypoestrogenism. Osteoporosis.

Hypoestrogenism due to: Female hypogonadism—2.5 mg to 7.5 mg daily in divided doses for 20 days followed by 10 day rest period. If bleeding does not occur by the end of this period, the same dosage schedule is repeated. Female castration or primary ovarian failure—1.25 mg daily, cyclically. Adjust upward or downward according to response of the patient. For maintenance, adjust dosage to lowest level that will provide effective control.

Osteoporosis—0.625 mg daily. Administration should be cyclic (eg, three weeks on and one week off).

PREMARIN® Brand of conjugated estrogens Vaginal Cream

Given cyclically for short-term use only. For treatment of atrophic vaginitis or kraurosis vulvae.

The lowest dose that will control symptoms should be chosen and medication should be discontinued as promptly as possible.

Attempts to discontinue or taper medication should be made at three- to six-month intervals.

Usual dosage range: 2 g to 4 g daily, intravaginally, depending on the severity of the condition.

Patients with an intact uterus who are treated with either PREMARIN Tablets or Vaginal Cream should be monitored for signs of endometrial cancer and appropriate measures taken to rule out malignancy in the event of persistent or recurring abnormal vaginal bleeding.

Revised August 21, 1989

THE DEPARTMENT OF OBSTETRICS AND GYNECOLOGY UNIVERSITY OF WISCONSIN MEDICAL SCHOOL

is seeking applicants for two (2) full-time faculty positions for a new women's health center and academic program at its Milwaukee Clinical Campus.

Sinai Samaritan Medical Center has recently consolidated its obstetrical and gynecological services in a redesigned facility in downtown Milwaukee. The department supports a residency program, the largest perinatal service in Wisconsin (5500 deliveries), consultative ultrasound, genetic and infectious disease programs, and reproductive/endocrine services (including an IVF program). The department is affiliated with Planned Parenthood of Wisconsin and St. Luke's Medical Center in Milwaukee.

Qualifications include a board candidacy or certification in obstetrics and gynecology and a commitment to teaching residents, medical students, and clinical research. Qualifications for the two positions for GENERAL OB/GYN can take into consideration special individual interests. Special expertise of interest for the department are:

—STATEWIDE FAMILY PLANNING
(Part-time medical director, Planned Parenthood)
—OPERATIVE LAPAROSCOPY, HYSTEROSCOPY
—UROGYNECOLOGY
—OB/GYN ULTRASOUND

Private practice opportunities are also available in an associated offsite multispecialty clinic and all faculty members participate in a group practice at the institution. Contact:

The University of Wisconsin Medical School is an equal opportunity employer

---

One full-time position is available in the Department of Obstetrics and Gynecology, University of California, Davis, Medical Center, Sacramento, as a perinatologist on the Maternal/Fetal Medicine Service with concurrent appointments to the faculty of the University of California, Davis, School of Medicine. Applicants should be Board eligible or certified in Obstetrics and Gynecology and must have successfully completed subspecialty training in Maternal/Fetal Medicine with subsequent Specialty Board eligibility and/or certification in Maternal Fetal Medicine. Applicants must possess or be eligible for medical licensure in the State of California. Applicants must demonstrate experience and competence in teaching effectiveness and research related activities or potential for such activities. Applicants must demonstrate experience in prenatal diagnosis, ultrasound and genetics.

Responsibilities of this position include direction and responsibility for research activities in the division, both inpatient and outpatient case management, surgery and procedures specific to high risk obstetrics, participation in teaching activities with residents, interns and medical students, development and/or participation in research activities and involvement in University and Hospital committees.

Send curriculum vitae and five references to:

R. Jeffrey Chang, M.D.
Chairman, Department of Obstetrics and Gynecology
University of California, Davis, Medical Center
1621 Alhambra Boulevard, Suite 2500
Sacramento, California 95816

The final date for receipt of applications is May 31, 1992.

The University of California, Davis is an equal opportunity, affirmative action employer.

THE DEPARTMENT OF OBSTETRICS & GYNECOLOGY at the University of Missouri-Columbia is recruiting for a full-time, tenure-track specialist in Gynecologic Oncology to direct the expansion and development of clinical and research activities in gynecologic oncology. Candidates should be Board Certified or active candidates in Obstetrics and Gynecology, and active candidates or Board certified in Gynecologic Oncology. Rank and salary commensurate with qualifications and experience. Applicants should contact Dr. James W. Daly, M.D., Chairman, Department of Obstetrics and Gynecology, University of Missouri-Columbia, Columbia, Missouri 65212 or phone (314) 882-6361. The University of Missouri is an Equal Opportunity/Affirmative Action Employer.

Gynecologic Oncologist

Columbia University

The Department of Obstetrics and Gynecology is seeking an additional Gynecologic Oncologist whose clinical duties will include instruction of residents and students, supervision of inpatient/outpatient care, and development of private practice. Research opportunities are available and encouraged. Candidates must be Board Certified or Board Eligible in Gynecologic Oncology. Salary will be commensurate with training, academic level and experience.

Please apply in writing to: Daniel H. Smith, M.D., Director of the Division of GYN/Oncology, College of Physicians and Surgeons, Columbia University, 630 West 168th Street, New York, NY 10032. Columbia University is an equal opportunity employer.

INFORMATION FOR AUTHORS

Editorial policies

The requirements for manuscripts submitted to the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY conform to the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" established by the International Committee of Medical Journal Editors (N Engl J Med 1991;324:424-8). Certain requirements unique to our JOURNAL are provided in Information for Authors, published in each issue of the JOURNAL.

Manuscript submission. Manuscripts should be submitted to one of the two Editors in Chief as follows:

1. **Dr. Zuspan**—manuscripts from the eastern and southeastern United States and from England, Israel, and Italy, manuscripts written for Clinical Opinion and Current Development, Letters to the Editors, and all manuscripts presented before one of the official sponsoring societies, except the Society for Gynecologic Investigation. *Manuscripts from The Society of Perinatal Obstetricians should be submitted to Dr. J. Peter Van Dorsten, P.O. Box 34, MCV Station, Richmond, VA 23298.*
2. **Dr. Quilligan**—manuscripts from states west of Pennsylvania, West Virginia, Kentucky, Tennessee, and Mississippi; manuscripts from Hawaii, Alaska, Canada, and abroad (except England, Israel, and Italy). Dr. Quilligan is responsible for manuscripts from the Society for Gynecologic Investigation. *Manuscripts from the Society for Gynecologic Investigation should be submitted to Dr. Roger A. Lobo, Women's Hospital, 1240 North Mission Road, Room 1M2, Los Angeles, CA 90033.*

Author's suggested reviewers. When authors submit their manuscripts, they must provide the names and addresses of at least three reviewers for consideration by the Editors.

Copyright statement. The specified copyright statement that follows the Information for Authors in each issue of the JOURNAL must be completed, signed by all authors, and submitted with the manuscript. If not completed in full, it will be returned to the author for completion. The copyright statement and checklist form may be torn from the JOURNAL or photocopied for submission.

Checklist. The checklist that appears with the copyright statement in each issue of the JOURNAL must be fully completed by the author(s) and sent with each submitted manuscript. A more complete description of each item that must be checked is provided under the appropriate heading in the Information for Authors, which is published in each issue of the JOURNAL. *If the checklist is not completed in full, the deficiencies will be noted, and the form, as well as the manuscript when necessary, will be returned to the author for completion.*

Previous publication. If a report by the same author(s) or some of the same authors has been previously published in any medium that deals in any respect whatsoever with the same patients, same animals, same laboratory experiments, or same data, in part or in full, as those reported in the manuscript being submitted, two reprints of the article(s) or two copies of the manuscript, be it a full-length report or an abstract, must be submitted with the manuscript. Two copies of a new manuscript being prepared for possible publication also must be submitted. The author(s) should inform the Editor of the circumstances, similarities, and differences of the reports. This requirement also applies to the submission of a manuscript in which a few different patients, animals, laboratory experiments, or data were added to those reported in a previous publication or in a submitted or accepted manuscript. Articles previously published in another language will not be considered.

Human and nonhuman experimentation. It is assumed by the Editors that manuscripts emanating from a particular institution are submitted with the approval of the

requisite authority. Human experimentation that requires local institutional approval must have this approval *before the experiment is started* and approval must be so indicated in the *Material and Methods* section of the submitted manuscript. Reports of experiments on nonhuman animals or other species must *state in the* Material and Methods *section of the manuscript* that the guidelines for the care and use of the animals *approved by the local institution* were followed. The type of nonhuman animals or other species used in an investigation must be named in the title, abstract, key words, and *Material and Methods* section of the manuscript.

Authorship. For manuscripts with two or more authors, each author must qualify by having participated actively and sufficiently in the study that is being performed and reported. The inclusion of each author in the authorship list of a report is based only (1) on substantial contributions to (a) concept and design, or analysis and interpretation of data and (b) drafting the manuscript or revising it critically for important intellectual content; and (2) on final approval by each author of the version of the manuscript. Conditions 1 (a and b) and 2 must both be met. Others contributing to the work should be recognized separately in an Acknowledgment. *In the covering letter that accompanies the submitted manuscript, it must be confirmed that all authors fulfilled both conditions.*

Conflict of interest. Authors are expected to inform the Editor, in a letter accompanying the submitted manuscript, of any commercial association that might pose a conflict of interest, such as ownership, stock holdings, equity interests and consultant activities, or patent-licensing situations. Such information is confidential, is not given to the consultants, and does not play a part in the decision of the quality or timeliness of the manuscript. If the manuscript is accepted, the author and the Editor will determine how best to release the information. The usual and customary listing of sources of support and institutional affiliations on the title page is proper and does not imply a conflict of interest; only where there is a possible conflict of interest is the author(s) expected to inform the Editor.

Disclaimer. Statements and opinions expressed in articles and communications herein are those of the author(s) and not necessarily those of the Editor(s) or Publisher, and the Editor(s) and Publisher disclaim any responsibility or liability for such material. Neither the Editor(s) nor the Publisher guarantees, warrants, or endorses any product or service advertised in this publication, nor do they guarantee any claim made by the manufacturer of such product or service.

General requirements for preparation of manuscripts

The original and two good-quality photocopies of the manuscript and three sets of black-and-white glossy prints of illustrations are required. See "Color figures" and "Computer-generated figures" for special requirements. Manuscripts must be submitted in English.

Manuscripts must be typed double-spaced on one side only of 22 × 28 cm (8½ × 11 inch) white bond paper with 1-inch margins at top, bottom, and sides. Number pages consecutively in the upper right-hand corner in the following order: title page, condensation, abstract, body of text, acknowledgments, references, figure legends, and tables.

Title page. The title page (page 1) should contain in sequence the title (concise and suitable for indexing purposes); author line with first name, middle initial, and last name of each author and each author's highest academic degree (both MD and PhD are acceptable, but honors degrees are not permitted); city(ies), state(s) in which the study was conducted; divisional, or departmental, and institutional affiliations at the time the study was performed; source(s) of financial support; presented line, if applicable; disclaimers, if any; name, address, business and home telephone numbers, and fax number of author to whom requests for reprints should be addressed (if reprints will not be available, it should be so stated); and name, address, business and home telephone numbers, and fax number of author responsible for correspondence concerning the manuscript if different from author to whom reprint requests are addressed. *At the bottom of the title page supply a short title for the running head not exceeding 52 characters (including word spaces).*

Condensation. On page 2 of the manuscript provide a brief, concise condensation, typed double-spaced, that will appear with the title in publication of the Contents pages of the JOURNAL. It should be a single sentence, limited to a maximum of 25 words, delineating the essential point(s) made in the manuscript.

Abstract page including key words/phrases. On manuscript page 3, type the abstract, double-spaced, with the required margins and headed by the title of the article and name(s) of author(s). Below the abstract, list 3 to 5 *key words or short phrases* for indexing purposes.

A structured abstract is required for certain types of articles and a *standard abstract format* is required for other types of articles; therefore the author(s) should select and prepare the appropriate abstract to be used in the submitted manuscript. This applies to both independently submitted and society manuscripts.

Structured abstract. A structured abstract, limited to 150 words, is to be used for regular articles, society articles, and Current Investigation articles; excluded are Clinical Opinion, Current Development, case report, and brief communication articles. The structured abstract is to contain the following major headings: *Objective(s); Study Design; Results;* and *Conclusion(s).* The *Objective(s)* reflects the purpose of the study, that is, the hypothesis that is being tested. The *Study Design* should include the setting for the study, the subjects (number and type), the treatment or intervention, and the type of statistical analysis. The *Results* include the outcome of the study and statistical significance if appropriate. The *Conclusion(s)* states the significance of the results.

Standard abstract. The standard abstract format is required for Clinical Opinion, Current Development, case report, and brief communication articles. The standard abstracts for Clinical Opinion and Current Development articles are to be 50 to 150 words and standard abstracts for case reports and brief communications are limited to 50 words. Even though the formal names of these four types of articles are not used, an author should determine his/her type of manuscript and prepare the appropriate standard abstract, regardless of whether it is to be submitted independently or as a part of a society's transactions.

Text. Do not hesitate to write your manuscript in the first person and active voice if they are more appropriate to the information you wish to convey. The passive voice is generally more effective for describing techniques or observations, since the emphasis is on the "action" rather than on the person performing the action.

Only standard abbreviations are to be used. Consult the

Estimating length of manuscripts

With the exception of Current Development articles, the length of text material (introduction through *Comment* section) in regular manuscripts accepted for publication normally ranges from 750 to 4200 words (an average of 2000 words). A text of 4200 words or more can seldom be accepted, especially if tables and figures are included. The average manuscript of 2000 words of text with abstract, 3 tables with captions, 2 figures with legends, and references makes a 5.7-page article in the JOURNAL. The 2000 words of text alone makes approximately 8 pages of manuscript typed double-spaced with the required 1-inch margins (approximately 250 words per page). A table or figure that occupies both columns of half a JOURNAL page is equivalent to approximately 500 words in manuscript. Thus, if a greater number of illustrations and tables is used, the length of the text should be adjusted accordingly.

Council of Biology Editors Style Manual or the AMA's *Manual of Style.* Abbreviations in the title are not acceptable. They should be avoided, if possible, in the abstract. In the text they should be kept to a practical minimum. The full term for which an abbreviation stands should precede its first use in the text unless it is a standard unit of measurement.

Either the generic, chemical, or proprietary names of drugs may be used. If the generic or chemical name is used, authors may, if they desire, insert the proprietary name in parentheses after the first mention in the text, with the name of the manufacturer and city and state.

Regular articles are customarily organized into the following sections: an introduction and headings that identify *Material and Methods*, *Results*, and *Comment*. Authors may wish to summarize their findings in a short paragraph at the end of the *Comment* section. This format may not be appropriate for some types of articles.

In the introduction, state concisely the purpose and rationale for the study and cite only the most pertinent references as background.

In the *Material and Methods* section describe briefly (but in sufficient detail to permit other workers to repeat the study) the plan, the patients, experimental animals or other species, material, and controls, the methods and procedures utilized, and the statistical method(s) employed.

In the *Results* section present the detailed findings. Include mentions of all tables and/or figures. Figures and tables should supplement, not duplicate, the text; presentation of data in either one or the other will suffice. Emphasize only your important observations; do not compare your observations with those of others. Such comparisons and comments are reserved for the *Comment* section.

In the *Comment* section state the importance and significance of your findings but do not repeat the details given in the *Results* section. Limit your opinions to those strictly indicated by the facts in your report. Compare your findings with those of others. No new data should be presented in this section.

Acknowledgments. Acknowledge only persons who have made substantive contributions to the study.

References. A reasonable number (25) is allowed, except in case reports and brief communications (limited to 2) and in manuscripts for the Current Development section (for which there is no limit). Number references consecutively in the order in which they are mentioned in the text. Use the format of the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" (Vancouver style) (N Engl J Med 1991;324:424-8). Journal titles should conform to abbreviations used in *Cumulated Index Medicus.*

Examples (if six or fewer authors, list all; if seven or more authors, list three then et al.):

JOURNAL: Flamm BL, Dunnett C, Fischermann E, Quilligan EJ. Vaginal delivery following cesarean section: use of oxytocin augmentation and epidural anesthesia with internal tocodynamic and internal fetal monitoring. AM J OBSTET GYNECOL 1984;148:759-63.

BOOKS: Ledger WJ. Dystocia and prolonged labor. In: Wilson JR, Carrington ER, eds. Obstetrics and gynecology. St. Louis: CV Mosby, 1987 vol 8:474-93.

Personal communications and unpublished data, if essential, may be used but not as numbered references. If they are used, they are to be referred to, within parentheses, at the appropriate location in the text. If used, the author(s) must obtain written and signed permission for their use from the individual being quoted. *This signed permission must accompany the manuscript when it is submitted to the Editor.* Published abstracts can be used as numbered references; however, reference to the complete published article is preferred.

Figures. The term *figure* includes all types of illustrations such as graphs, diagrams, photographs, flow charts, and line drawings. A reasonable number of figures will be reproduced without charge, but special arrangements must be made with the Editors for color figures at an additional charge to the author. The quoted charge is per page of color, and as many as eight color figures can be included on one page if the color balance is appropriate.

Figures must be cited consecutively in the text in Arabic numerals and identified with a gummed label on the back of the figure with author(s) name(s), title of article, figure number, and top marked clearly. Consistency in size within the article is strongly preferred. Any special instructions regarding sizing should be clearly noted. Do not use paper clips or mar the surface of figures in any way. Figures will be returned only on request by the author.

For *black-and-white figures,* submit three sets of 3 × 4 inch (minimum) to 5 × 7 inch (maximum) unmounted, glossy prints. All lettering must be done with commercially available paste-on letters (or numbers) or by a professional; typed or freehand lettering is not acceptable. All lettering must be in proportion to the drawing, graph, or photograph. Original drawings, appropriately done in black India ink, roentgenograms, and other material must be submitted as glossy prints with good black-and-white contrast.

For *color figures* submit original transparencies and two sets of unmounted prints on glossy (smooth surface) paper. Polaroid prints are not acceptable. Color transparencies must have a color balance (consistency in lighting and film speed) that is acceptable to the author and Editors before acceptance for publication. Please note that 35 mm transparencies are enlarged to twice their original size. If it is important to deviate from this standard, please so indicate when the material is submitted. The top, first author's last name, and figure number must be indicated on the front of each transparency and the back of each print.

Computer-generated figures must be legible and clearly printed in jet black ink on heavy coated paper with either a glossy or dull finish. Any patterns or shadings must be dark enough for reproduction and must be distinguishable from each other. Lines, symbols, and letters should be both smooth and complete. The legend should not appear on the figure. On the back of each figure the name of the first author and the figure number should be given and the top indicated. Three original individual laser or plotter prints are to be submitted *unmounted* with the manuscript. Laser prints should be full size at 300 dots per inch (DPI) or greater full-page resolution; multiple illustrations on a page cannot be accepted. Dot matrix prints and photographic halftones are not acceptable. *Color figures* are acceptable, but special arrangements must be made with the Editors. The colors used must be dark enough and of sufficient contrast for reproduction. With the exception of fluorescent colors, all colors can be reproduced in four-color figures.The preparation and submitting of color prints should follow the preceding guidelines for black-and-white computer-generated illustrations.

Legends to figures. Legends for all figures must be typed together in numeric order double-spaced on one sheet of paper (or more if necessary) separate from the text of the manuscript. This page must be numbered in sequence after the references. Titles should be included in the legend, not on the print. Original magnifications should be provided. If a figure has been taken from copyrighted material, the legend must give full credit to the original source.

Tables. Tables should be typed on separate sheets of paper, one table to a page, and included at the end of the text. They should be numbered in Roman numerals. Each table must be cited in sequence at an appropriate point in the text. Titles should be brief yet indicate clearly the purpose or content of each table, and each column should be precisely defined by headings. Abbreviations and special designations should be explained in a footnote to the table. If a table or any part thereof has been taken from copyrighted material, a footnote to the table must give full credit to the original source. Arrangements must be made with the Editors for elaborate tables because of space limitations.

Permissions. Direct quotations, tables, or figures that have appeared in copyrighted material must be accompanied by written permission for their use from *the copyright owner and original author* along with complete reference information. Photographs of identifiable persons must be accompanied by signed releases. If not, all recognizable features must be masked.

Requirements for certain types of manuscripts

Case reports and brief clinical and basic science communications. Limit of 700 words, 2 references. Include *standard abstract format*, of 50 words maximum, 3 to 5 key words/phrases for indexing purposes, and short title. If tables and/or figures are used, an equivalent number of words must be deducted from the total (see "Estimating Length of Manuscript").

Current Investigation. Same requirements as for regular article. The abstract *must* follow the *structured format.*

Clinical Opinion. Limit of 3000 words. Include *standard abstract format* of 50 to 150 words, 3 to 5 key words/phrases, and short title. Submit to Dr. Zuspan.

Current Development. Limit of 6000 words. Include *standard abstract format* of 50 to 150 words, 3 to 5 key words/phrases, and short title. Submit to Dr. Zuspan.

Letters to the Editors. *Letters to the Editors* must be submitted in duplicate, typed double-spaced, and the text of the manuscript must be limited to a maximum of 400 words (excluding references, name[s] and address[es] of the signer[s], and the phrase "To the Editors"). The submitted *Letter to the Editors* must be accompanied by a signed copyright statement. If there are two or more signers of the *Letter to the Editors,* one of the authors may sign the copyright statement but must add to the statement the following: "I sign for and accept responsibility for releasing this letter on behalf of any and all cosigners." These requirements apply to all types of *Letters to the Editors.* Letters should be sent to Dr. Zuspan.

Two types of letters will be considered for publication. (1) A *Letter to the Editors* commenting on an article that has appeared in the JOURNAL should be brief and directly related to the published article. The editorial staff reserves the right to shorten letters if necessary and to make minor editorial alterations without reference to the writer. Letters may be published together with a reply from the original author. If the original author does not respond, a notation indicating "Response declined" will be published. As space for letters is limited, only a selection of letters submitted may be published. (2) A brief case presentation or a short report of a pertinent observation in the form of a *Letter to the Editors* will be considered for publication.

Announcements. Announcements of major meetings and other significant activities must be received at least 8 weeks before the desired month of publication. All announcements carry a charge of $60 U.S., and the fee must accompany the request to publish. Information will be limited to title of meeting, date, place, and an address to obtain further information. Send announcements and payment, payable to this JOURNAL, to Kay G. Goehler, Senior Manuscript Editor, Journal Editing, Mosby–Year Book, Inc., 11830 Westline Industrial Drive, St. Louis, MO 63146-3318.

Books. Books received will be listed in the JOURNAL. They should be sent to Dr. Zuspan. No books will be returned.

Reprints

The corresponding author will receive a price schedule and order form at the time of publication. Reprints in quantities must be ordered from the Publisher with the author's consent.

Business communications

Communications of a business nature and all advertising communications should be addressed to: Journal Publisher, Mosby–Year Book, Inc., 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, or call Journal Advertising Production Manager (1-800-325-4177, ext. 4306, or 314-453-4306).

CHECKLIST AND COPYRIGHT STATEMENT

Both the checklist and the copyright statement forms **must be completed** and sent with each submitted manuscript. If **not** completed, these forms will be returned to the author for completion.

These items appear in each monthly issue of the JOURNAL. A photocopy may be used. An exposition of the requirements given in the checklist is in the Information for Authors, which is published in each issue of the JOURNAL.

CHECKLIST

General

—The original and two copies of the manuscript are submitted.
—The completed checklist is enclosed. The assignment of copyright signed by **all** authors accompanies the manuscript.
—Human experimentation has been approved by the local institution as stated in the *Material and Methods* section.
—Guidelines for the care and use of *nonhuman* animals or *other species* approved by the institution have been followed as indicated in the *Material and Methods* section. *The species is named in the title, abstract, key words, and* Material and Methods *section.*
—The covering letter with essential information is with the manuscript.
—All elements of the manuscript are typed in English double-spaced on bond paper with 1-inch margins at top, bottom, and sides.
—All pages are numbered in the following order: title page, condensation, structured or standard abstract, body of the text, acknowledgments only of persons who have made substantive contributions to the study, references, legends, and tables.
—Signed, written permission from both the copyright holder and the original author for the use of tables, figures, or quotations previously published and their complete references are enclosed with the manuscript.
—Signed, written permission for the use of quotations of personal communications and unpublished data has been obtained from the person(s) being quoted and is enclosed.

Authorship

—In the covering letter that accompanies the submitted manuscript I/we have confirmed that all authors fulfilled both conditions required for authorship.

Conflict of interest

—In the covering letter that accompanies the submitted manuscript the commercial association of the author or of any coauthors that might pose a conflict of interest is described.

Previous publications

—Enclosed with the submitted manuscript are two reprints each of articles the author and/or some of the coauthors have previously published, have submitted for possible publication, or have in manuscript form dealing with same patients, same animals, same laboratory experiment, or same data, in part or in full, as those reported in the submitted manuscript. Further explanation is provided in the covering letter that accompanies the submitted manuscript.
—Similarities, differences and explanation are provided in the covering letter that accompanies the submitted manuscript.

Reviewers

—Names and addresses of three suggested reviewers are enclosed.

Title page

—These elements are given in the following sequence, and are typed double-spaced.
—Title.
—Author(s) name(s) and highest academic degree(s) are shown.
—City(ies), state(s), and country other than United States in which the study was conducted are given.
—The name(s) of the institution(s) section(s), division(s), department(s) in which the study was performed is provided and the institutional affiliation(s) of the author(s) at the time of the study is indicated.
—Acknowledgment of financial support is cited.
—Name, address, business and home telephone numbers, and fax number of author to whom requests for reprints are to be sent are included.
—If reprints will not be available, this has been stated on the title page.
—If the corresponding author is different from the author to whom reprint requests are to be sent, his/her name, address, business and home telephone numbers, and fax number have been added.
—At the bottom of the page, a running head not exceeding 52 characters (including word spaces) has been typed.

Condensation

—On a separate sheet of paper, page 2 of the manuscript, a single sentence limited to 25 words delineating the essential point(s) is typed double-spaced.

Abstract and key words or short phrases

—The abstract (structured or standard format) is typed double-spaced with required margins on page 3 headed by the title and author(s) name(s). Beneath the abstract 3 to 5 key words or short phrases are typed.
—A *structured abstract,* with 150 words or less, is submitted as required for regular articles, society regular-type articles, and Current Investigation articles. The abstract contains the four required major headings: Objective(s), Study Design, Results, and Conclusion(s), each with a brief adequate presentation.
—A *standard abstract* is submitted as required for Clinical Opinion and Current Development articles with 50 to 150 words and for case reports and brief communications articles with a maximum of 50 words, be they independent or society articles.

References

—Are typed double-spaced.

—Are numbered consecutively in the order they are cited in the text.

—The format of the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" is used. Examples shown in Information for Authors have been followed.

—Personal communications and unpublished observations are not used as numbered references but are mentioned in the text with the written approval of the person being quoted. The signed approval is enclosed.

Figures

—Each is numbered with an Arabic numeral and cited in numeric sequence in the text.

—Three sets of unmounted glossy prints for *black-and-white* figures are submitted, properly numbered, labeled, and *top indicated* on the back of each print.

—Three sets of original computer-generated figures printed on heavy coated paper with either a glossy or dull finish, unmounted, each one on a page, and properly labeled on the back and *top indicated* are submitted. None are dot matrix or photographic prints.

—Original transparencies of *color photographs* appropriately numbered and identified and *top indicated* are submitted along with two sets of unmounted prints on glossy paper, numbered and identified on the back.

Figure legends

—Are provided for each figure.

—Are numbered and typed together in numeric order on one sheet of paper (more if necessary). The page is numbered in sequence after the References page(s).

Tables

—Each table headed by a title and numbered in Roman numerals is typed double-spaced on a separate page.

—Tables are cited in numeric sequence in the text.

TRI-LEVLEN® 28 TRI-LEVLEN® 21

BRIEF SUMMARY

Tri-Levlen®—6 brown tablets, each containing 0.050 mg of levonorgestrel (d(-)-13 beta-ethyl-17-alpha-ethinyl-17-beta-hydroxygon-4-en-3-one), a totally synthetic progestogen, and 0.030 mg of ethinyl estradiol (19-nor-17α-pregna-1,3,5(10)-trien-20-yne-3, 17-diol); 5 white tablets, each containing 0.075 mg levonorgestrel and 0.040 mg ethinyl estradiol; 10 light-yellow tablets, each containing 0.125 mg levonorgestrel and 0.030 mg ethinyl estradiol (7 light-green tablets containing inert ingredients are included in the 28-day triphasic regimen).

Indications and Usage

Oral contraceptives are indicated for the prevention of pregnancy in women who elect to use this product as a method of contraception.

Contraindications

Oral contraceptives should not be used in women with any of the following conditions: thrombophlebitis or thromboembolic disorders, a past history of deep-vein thrombophlebitis or thromboembolic disorders, cerebral-vascular or coronary-artery disease, known or suspected carcinoma of the breast, carcinoma of the endometrium or other known or suspected estrogen-dependant neoplasia, undiagnosed abnormal genital bleeding, cholestatic jaundice of pregnancy or jaundice with prior pill use, hepatic adenomas or carcinomas, known or suspected pregnancy.

Warnings

Cigarette smoking increases the risk of serious cardiovascular side effects from oral-contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia, gallbladder disease, and hypertension, although the risk of serious morbidity or mortality is very small in healthy women without underlying risk factors. The risk of morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemias, obesity and diabetes. Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks. The information contained in this package insert is principally based on studies carried out in patients who used oral contraceptives with higher formulations of estrogens and progestogens than those in common use today. The effect of long-term use of the oral contraceptives with lower formulations of both estrogens and progestogens remains to be determined. Throughout this labeling, epidemiological studies reported are of two types: retrospective or case control studies and prospective or conort studies. Case control studies provide a measure of the relative risk of disease, namely, a ratio of the incidence of a disease among oral-contraceptive users to that among nonusers. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide a measure of attributable risk, which is the difference in the incidence of disease between oral-contraceptive users and nonusers. The attributable risk does provide information about the actual occurrence of a disease in the population. For further information, the reader is referred to a text on epidemiological methods.

1. *Thromboembolic Disorders and Other Vascular Problems*

a. *Myocardial Infarction.* An increased risk of myocardial infarction has been attributed to oral-contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary-artery disease such as hypertension, hypercholesterolemia, morbid obesity, and diabetes. The relative risk of heart attack for current oral-contraceptive users has been estimated to be two to six. The risk is very low under the age of 30. Smoking in combination with oral-contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women in their mid-thirties or older with smoking accounting for the majority of excess cases. Mortality rates associated with circulatory disease have been shown to increase substantially in smokers over the age of 35 and non-smokers over the age of 40 among women who use oral contraceptives. Oral contraceptives may compound the effects of well-known risk factors, such as hypertension, diabetes, hyperlipidemias, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and cause glucose intolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see section 9 in "Warnings"). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors.

b. *Thromboembolism.* An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to nonusers to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep-vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. Cohort studies have shown the relative risk to be somewhat lower, about 3 for new cases and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease due to oral contraceptives is not related to length of use and disappears after pill use is stopped. A two-to four-fold increase in relative risk of postoperative thromboembolic complications has been reported with the use of oral contraceptives. The relative risk of venous thrombosis in women who have predisposing conditions is twice that of women without such medical conditions. If feasible, oral contraceptives should be discontinued at least four weeks prior to and for two weeks after elective surgery of a type associated with an increase in risk of thromboembolism and during and following prolonged immobilization. Since the immediate post partum period is also associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than four to six weeks after delivery in women who elect not to breast-feed, or a midtrimester pregnancy termination.

c. *Cerebrovascular diseases.* Oral contraceptives have been shown to increase both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes), although, in general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and nonusers, for both types of strokes, while smoking interacted to increase the risk for hemorrhagic strokes. In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for nonsmokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 7.6 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk is also greater in older women.

d. *Dose-related risk of vascular disease from oral contraceptives.* A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high-density lipoproteins (HDL) has been reported with many progestational agents. A decline in serum high-density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the nature and absolute amount of progestogen used in the contraceptive. The amount of both hormones should be considered in the choice of an oral contraceptive. Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral-contraceptive agents should be started on preparations containing less than 50 mcg of estrogen.

e. *Persistence of risk of vascular disease.* There are two studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40-49 years who had used oral contraceptives for five or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. However, both studies were performed with oral-contraceptive formulations containing 50 micrograms or higher of estrogens.

2. *Estimates of Mortality from Contraceptive Use.* One study gathered data from a variety of sources which have estimated the mortality rate associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral-contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is less than that associated with childbirth. The observation of a possible increase in risk of mortality with age for oral-contraceptive users is based on data gathered in the 1970's—but not reported until 1983. However, current clinical practice involves the use of lower estrogen dose formulations combined with careful restriction of oral-contraceptive use to women who do not have the various risk factors listed in this labeling. Because of these changes in practice and, also, because of some limited new data which suggest that the risk of cardiovascular disease with the use of oral contraceptives may now be less than previously observed, the Fertility and Maternal Health Drugs Advisory Committee was asked to review the topic in 1989. The Committee concluded that although cardiovascular-disease risks may be increased with oral-contraceptive use after age 40 in healthy nonsmoking women (even with the newer low-dose formulations), there are greater potential health risks associated with pregnancy in older women and with the alternative surgical and medical procedures which may be necessary if such women do not have access to effective and acceptable means of contraception. Therefore, the Committee recommended that the benefits of oral-contraceptive use by healthy nonsmoking women over 40 may outweigh the possible risks. Of course, older women, as all women who take oral contraceptives, should take the lowest possible dose formulation that is effective.

3. *Carcinoma of the Reproductive Organs.* Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. The overwhelming evidence in the literature suggests that use of oral contraceptives is not associated with an increase in the risk of developing breast cancer, regardless of the age and parity of first use or with most of the marketed brands and doses. The Cancer and Steroid Hormone (CASH) study also showed no latent effect on the risk of breast cancer for at least a decade following long-term use. A few studies have shown a slightly increased relative risk of developing breast cancer, although the methodology of these studies, which included differences in examination of users and nonusers and differences in age at start of use, has been questioned. Some studies suggest that oral-contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors. In spite of many studies of the relationship between oral-contraceptive use and breast and cervical cancers, a cause-and-effect relationship has not been established.

4. *Hepatic Neoplasia.* Benign hepatic adenomas are associated with oral-contraceptive use, although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases/100,000 for users, a risk that increases after four or more years of use. Rupture of rare, benign, hepatic adenomas may cause death through intra-abdominal hemorrhage. Studies from Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral-contraceptive users. However, these cancers are extremely rare in the U.S. and the attributable risk (the excess incidence) of liver cancers in oral-contraceptive users approaches less than one per million users.

5. *Ocular Lesions.* There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia; papilledema; or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately.

6. *Oral-Contraceptive Use Before or During Early Pregnancy.* Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. Studies also do not suggest a teratogenic effect, particularly insofar as cardiac anomalias and limb-reduction defects are concerned, when taken inadvertently during early pregnancy. The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion. It is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing oral-contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral-contraceptive use should be discontinued if pregnancy is confirmed.

7. *Gallbladder Disease.* Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral-contraceptive users may be minima. The recent findings of minimal risk may be related to the use of oral-contraceptive formulations containing lower hormonal doses of estrogens and progestogens.

8. *Carbohydrate and Lipid Metabolic Effects.* Oral contraceptives have been shown to cause glucose intolerance in a significant percentage of users. Oral contraceptives containing greater than 75 micrograms of estrogens cause hyperinsulinism, while lower doses of estrogen cause less glucose intolerance. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the nondiabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects, prediabetic and diabetic women should be carefully observed while taking oral contraceptives. A small proportion of women will have persistent hypertriglyceridemia while on the pill. As discussed earlier (see "Warnings" 1a. and 1d.), changes in serum triglycerides and lipoprotein levels have been reported in oral-contraceptive users.

9. *Elevated Blood Pressure.* An increase in blood pressure has been reported in women taking oral contraceptives and this increase is more likely in older oral-contraceptive users and with continued use. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing quantities of progestogens. Women with a history of hypertension or hypertension-related diseases, or renal disease should be encouraged to use another method of contraception. If women with hypertension elect to use oral contraceptives, they should be monitored closely, and if significant elevation of blood pressure occurs, oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives, and there is no difference in the occurrence of hypertension among ever-and never-users.

10. *Headache.* The onset or exacerbation of migraine or development of headache with a new pattern that is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause.

11. *Bleeding Irregularities.* Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first three months of use. The type and dose of progestogen may be important. Nonhormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding, as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out. Some women may encounter post-pill amenorrhea or oligomenorrhea, especially when such a condition was preexistent.

Precautions

1. PHYSICAL EXAMINATION AND FOLLOW UP. A complete medical history and physical examination should be taken prior to the initiation or reinstitution of oral contraceptives and at least annually during use of oral contraceptives. These physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, including cervical cytology, and relevant laboratory tests. In case of undiagnosed, persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be conducted to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care. 2. LIPID DISORDERS. Women who are being treated for hyperlipidemias should be followed closely if they elect to use oral contraceptives. Some progestogens may elevate LDL levels and may render the control of hyperlipidemias more difficult. (See "Warnings" 1d.) 3. LIVER FUNCTION. If jaundice develops in any woman receiving such drugs, the medication should be discontinued. Steroid hormones may be poorly metabolized in patients with impaired liver function. 4. FLUID RETENTION. Oral contraceptives may cause some degree of fluid retention. They should be prescribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention. 5. EMOTIONAL DISORDERS. Patients becoming significantly depressed while taking oral contraceptives should stop the medication and use an alternate method of contraception in an attempt to determine whether the symptom is drug related. Women with a history of depression should be carefully observed and the drug discontinued if depression recurs to a serious degree. 6. CONTACT LENSES. Contact-lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist. 7. DRUG INTERACTIONS. Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar association, though less marked, has been suggested with barbiturates, phenylbutazone, phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines. 8. INTERACTIONS WITH LABORATORY TESTS. Certain endocrine-and liver-function tests and blood components may be affected by oral contraceptives: a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3; increased norepinephrine-induced platelet aggregability. b. Increased thyroid-binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radioimmunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG, free T4 concentration is unaltered. c. Other binding proteins may be elevated in serum. d. Sex-binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged. e. Triglycerides may be increased. f. Glucose tolerance may be decreased. g. Serum folate levels may be depressed by oral-contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives. 9. CARCINOGENESIS. See "Warnings" section. 10. PREGNANCY. Pregnancy Category X. See "Contraindications" and "Warnings" sections. 11. NURSING MOTHERS. Small amounts of oral-contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child.

Information for the Patient

See Patient Labeling.

Adverse Reactions

An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see "Warnings" section): thrombophlebitis, arterial thromboembolism, pulmonary embolism, myocardial infarction, cerebral hemorrhage, cerebral thrombosis, hypertension, gallbladder disease, hepatic adenomas or benign liver tumors.

There is evidence of an association between the following conditions and the use of oral contraceptives, although additional confirmatory studies are needed: mesenteric thrombosis, retinal thrombosis.

The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug related: nausea; vomiting; gastrointestinal symptoms (such as abdominal cramps and bloating); breakthrough bleeding; spotting; change in menstrual flow; amenorrhea; temporary infertility after discontinuation of treatment; edema; melasma which may persist; breast changes: tenderness, enlargement, secretion; change in weight (increase or decrease); change in cervical erosion and secretion; diminution in lactation when given immediately postpartum; cholestatic jaundice; migraine; rash (allergic); mental depression; reduced tolerance to carbohydrates; vaginal candidiasis; change in corneal curvature (steepening); intolerance to contact lenses.

The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted: congenital anomalies, premenstrual syndrome, cataracts, optic neuritis, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, hirsutism, loss of scalp hair, erythema multiforme, cerebral-vascular disease with mitral valve prolapse, lupus-like syndromes, erythema nodosum, hemorrhagic eruption, vaginitis, porphyria, impaired renal function, hemolytic uremic syndrome, Budd-Chiari syndrome, acne, changes in libido, colitis, sickle-cell disease.

Overdosage

Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea, and withdrawal bleeding may occur in females.

Noncontraceptive Health Benefits

The following noncontraceptive health benefits related to the use of oral contraceptives are supported by epidemiological studies which largely utilized oral-contraceptive formulations containing doses exceeding 0.035 mg of ethinyl estradiol or 0.05 mg of mestranol.

Effects on menses: increased menstrual cycle regularity, decreased blood loss and decreased incidence of iron-deficiency anemia, decreased incidence of dysmenorrhea.

Effects related to inhibition of ovulation: decreased incidence of functional ovarian cysts, decreased incidence of ectopic pregnancies.

Effects from long-term use: decreased incidence of fibroadenomas and fibrocystic disease of the breast, decreased incidence of acute pelvic inflammatory disease, decreased incidence of endometrial cancer, decreased incidence of ovarian cancer.

Dosage and Administration

To achieve maximum contraceptive effectiveness, TRI-LEVLEN® tablets (Levonorgestrel and Ethinyl Estradiol Tablets—Triphasic Regimen) must be taken exactly as directed and at intervals not exceeding 24 hours.

For full details on dosage and administration see prescribing information in package insert. 60627-0 5/90

EDITORIAL

Summary of analysis of published articles

September 1, 1990, through August 31, 1991

Each year a retrospective analysis of the articles published in the JOURNAL is presented to the readers and also to the Editorial Board and the Advisory Committee on Policy. Over the past twenty-two years we have compiled data on the classification, category, and type of articles accepted and published. A comparison of the data for the last two years is presented in Table I. A comparison of publication time in the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY of regular articles (excluding society articles) for 1986-1987 through 1990-1991 is shown graphically in Fig. 1, on page 774.* The pie charts on page 774 show the articles and page utilization for 1990-1991 by classification (Fig. 2A) and category (Fig. 2B).

*Publication time of regular articles from time of acceptance to publication: 1986-1987, 4.9 months; 1987-1988, 5.2 months; 1988-1989, 5.6 months; 1989-1990, 5.1 months; and 1990-1991, 5.1 months.

Embryoscopy: A closer look at first-trimester diagnosis and treatment

E. Albert Reece, MD, Siegfried Rotmensch, MD, John Whetham, MD, Mark Cullen, MD, and John C. Hobbins, MD

Philadelphia, Pennsylvania, and New Haven, Connecticut

Advancing technology has made the fetus and its environment even more accessible to prenatal diagnosis and treatment. The current approach to prenatal diagnosis relies mainly on the use of high-resolution ultrasonography. However, as attempts are made to conduct antenatal diagnoses earlier in gestation, the limits of ultrasonography are approached. Embryoscopy allows for direct visualization of the first-trimester fetus with a fiberoptic endoscope. A customized side channel enables the operator to pass a variety of diagnostic tools and gain access into the fetal circulation. The further development and refinement of this technology are expected to change early prenatal diagnosis and treatment considerably. The potential contribution of this technique to perinatal medicine is readily apparent when it is placed in historic context. Undoubtedly, many ethical, legal, and regulatory questions will have to be addressed before the full potential of embryoscopy is realized. The responsibility for the judicious use of this powerful technology for prenatal intervention will have to be shared by the scientific community and a well-informed public. (Am J Obstet Gynecol 1992;166:775-80.)

Key words: Prenatal diagnosis, embryoscopy, perinatal medicine

Throughout history, the development of the human fetus has been considered a mystery, hidden within the walls of the uterus. The fetus and its compartment were considered off limits and regarded as a sacred enigma. Pregnancy mysteriously eventuated in either a normal infant or an anomalous one.

Recently, a fundamental transition toward a different concept has occurred. Advancing technology has rendered the fetus and its environment accessible to the "outside" world and therefore to diagnosis and therapy. Among the latest of such technologies is embryoscopy, which utilizes high-resolution fiberoptic equipment for direct visualization of the embryo-fetus. The importance of embryoscopy to perinatal medicine and its potential contributions to the concept of fetal therapy are readily apparent when the technique is placed in a historic context.

In the late 1930s, indirect visualization of the fetus by radiographic techniques, with and without contrast enhancement, began to be utilized. The first direct transuterine visualization of the fetus was successfully performed by Westin[1] in 1954 using a 10 mm hysteroscope. In spite of the image quality being rather limited by the insufficient optical system, fetal parts and movements could be identified. Nevertheless, even without optimal delineation of the fetal structure, the invasion of the fetal compartment had begun, and the stage was set for targeted fetal diagnosis and direct in utero therapy.

The advent of amniocentesis for Rh isoimmunization in the 1950s, followed by genetic amniocentesis in the 1960s, was a major milestone in the development of fetal intervention. Donald et al.[2] introduced ultrasonography into obstetrics and gynecology in 1958 and paved the way for the widespread use of an extremely powerful modality of fetal visualization. The static-image ultrasonographic scan enabled us to learn about fetal and uterine morphologic features and resulted in a blossoming of descriptive literature on the fetus. Before long, advancing technology yielded the gray-scale dynamic ultrasonographic image, which added yet another dimension to our understanding. Not only did the real-time scanner improve visualization, but for the first time some aspects of human fetal physiology were observed in vivo. Investigators were fascinated by the "live" observation of fetal body and limb movements,

breathing movements, bladder filling and emptying, heart motion, swallowing, and gastric filling dynamics. Circadian rhythms and periodicity of fetal physiologic functions were discovered and correlated with maternal physiologic status.[3]

Prenatal diagnosis of congenital anomalies improved exponentially with the advanced resolution of modern ultrasonography equipment.[4] In conjunction with electronic fetal heart rate monitoring, a rapidly evolving concept of fetal well-being emerged to have a significant impact on the practice of obstetrics. The interest of our specialty shifted its focus from the delivery process and associated surgical skills to the quest for understanding fetal biology. It became clear that fetal pathologic conditions could not be interpreted correctly if normal fetal biologic characteristics remained insufficiently understood.

The missing link for the achievement of this goal was access to the fetal circulation. Most physiologic and biochemical processes in the fetus were expected to result in alterations of metabolic products in the fetal blood circulation, similar to those of an adult. Boenisch and Saling[4a] translated this concept into the technique of intrapartum determination of fetal capillary scalp blood pH for detection of fetal distress. This technique was an important step toward an understanding of fetal acid-base status; however, it remained limited to parturition.

Initial attempts at gaining access to the fetal circulation during fetal development focused on ultrasonography-guided aspiration of fetal blood from the placenta. This approach was hampered by significant difficulties in obtaining pure fetal blood specimens and by relatively low success rates. In the early 1970s, Valenti[5] and Scrimgeour[6] reported the use of 6 and 2.2 mm endoscopes, respectively, for examination of the human fetus. Their techniques involved exposing the uterus by laparotomy and inserting the instruments through myometrial incisions. The widespread diagnostic and therapeutic use of fetoscopy in ongoing pregnancies became feasible when Hobbins and Mahoney[7] developed the Dyonics needlescope instrument, which used an ultrasonographically guided percutaneous transabdominal technique with the patient under local anesthesia. Direct fetal visualization allowed for the diagnosis of external structural anomalies, aspiration of fetal blood, and skin, liver, and fetal tumor biopsies, as well as for intravascular infusion of blood and blood products.[8, 9] The foundation for fetal medicine as a subspecialty in its own right had been laid.

Major drawbacks of fetoscopy, however, were related to a fetal loss rate of 4% to 8%, as well as to inconsistent success in obtaining fetal blood samples devoid of amniotic fluid contamination[10]; risk-versus-benefit considerations somewhat limited the use of fetoscopy. Addi-

Fig. 2. As endoscope is passed transcervically into exocoelomic space, clear, wavy amnion can be seen, through which undersurface of "placenta" can be visualized.

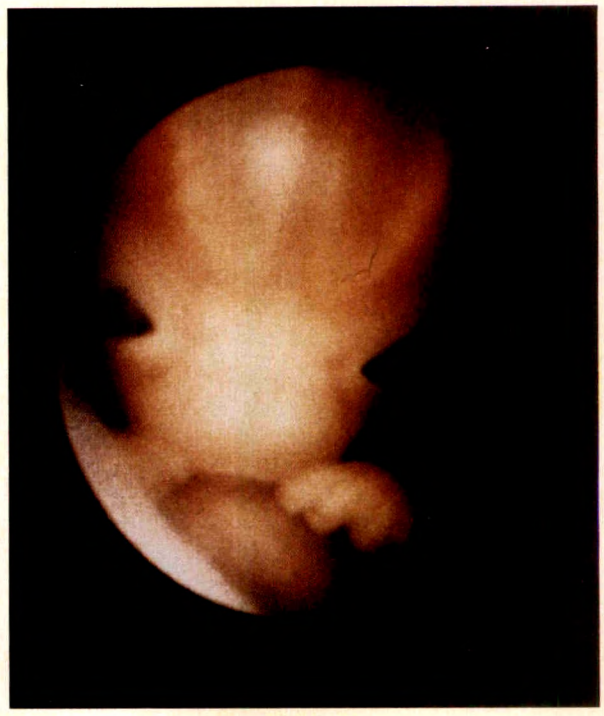

Fig. 3. Direct visualization of fetus at 9 weeks (menstrual). Head is seen flexed on its chest with prominent forehead, normal separated eyes, and fused lips. Fingers at this age are only slightly webbed.

tionally, fetoscopy could not be used when the amniotic fluid was discolored and was less efficacious in advanced pregnancies.

With the dramatic improvement in ultrasonography technology, Daffos et al.[11] were the first to substitute direct vision for ultrasonographic guidance of a spinal needle for percutaneous umbilical blood sampling. This technique quickly replaced fetoscopy for many diagnostic and therapeutic indications because of its safety, simplicity, and ability to obtain 100% pure fetal blood. Consequently, our understanding of fetal infectious disease, fetal metabolism, and transplacental pharmacologic characteristics was greatly enhanced, and important work on the pathophysiologic parameters of intrauterine growth retardation and fetuses of diabetic mothers continues.

All of the above-described diagnostic and therapeutic techniques are limited to use during the second and third trimesters; the first-trimester embryo and fetus have so far received only some diagnostic and relatively little therapeutic attention. Of course, chorionic villus sampling (CVS) can be performed as early as 6 weeks' gestation and provides extremely valuable genetic information. Furthermore, the utility of CVS has recently been enhanced by powerful techniques of deoxyribonucleic acid (DNA) analysis and our growing knowledge of DNA sequence. However, the diagnostic capability of CVS is limited by the degree to which trophoblastic and embryonic tissue is genetically congruent. Additionally, non–genetically determined structural anomalies are beyond the diagnostic scope of CVS. First-trimester ultrasonography, particularly transvaginal scanning, can diagnose major anomalies relatively early.[12] It appears, however, that the limits of sound wave resolution, with currently used frequencies, have been rapidly approached, particularly when it comes to minor malformations. None of these techniques can be used for treatment of the embryo.

Embryoscopy

Embryoscopy is a recently introduced technique that consists of transcervical fiberoptic endoscopy of the first-trimester embryo-fetus. It can be performed as early as 5 weeks' menstrual age. A side channel, customized for our instrument, allows for the passage of an aspiration needle for access to the embryonic blood circulation. Currently, this is the only instrument that allows direct visualization of the human embryo in vivo and access to its circulation. Multiple diagnoses of embryonic malformations have been made by embryoscopy; however, the diagnostic and therapeutic potential is just beginning to unfold.

Technique

The technical aspects of the procedure have been described elsewhere.[13, 14] In brief, embryoscopy utilizes

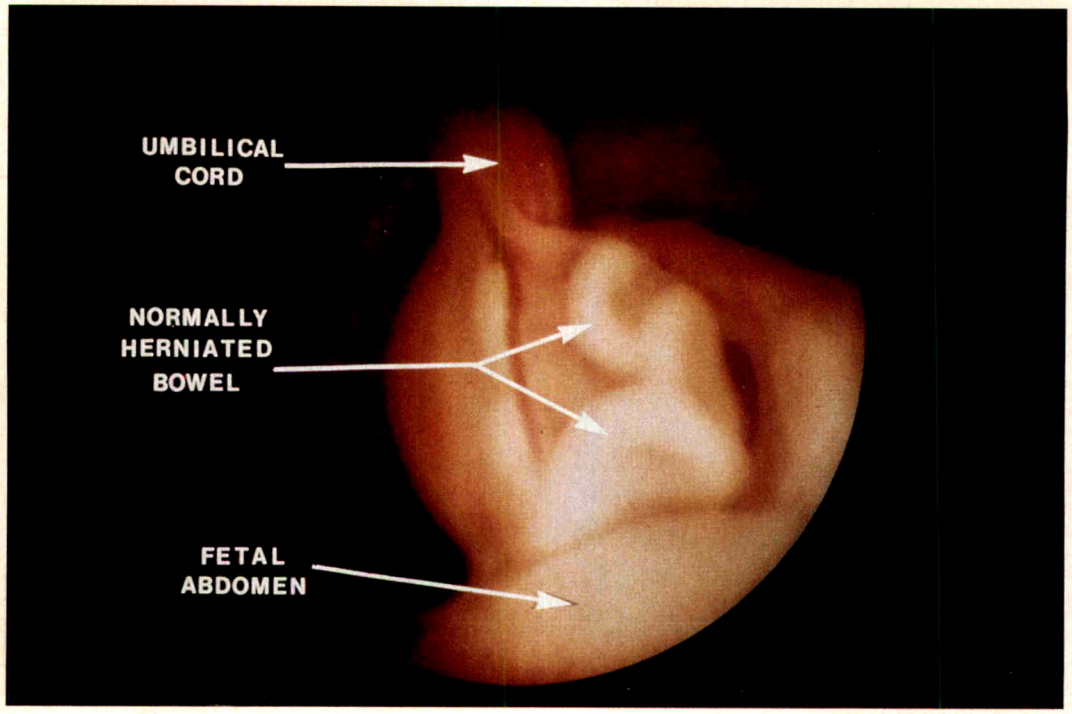

Fig. 4. Fetus with physiologic hernia at 9 weeks' gestation. Bowel can be seen herniating in base of umbilical cord. After 11 weeks' gestation failure of bowel contents to return leads to diagnosis of omphalocele.

a rigid fiberoptic endoscope, 30 cm in length, with diameters from 2.0 to 3.5 mm and a 0- or 30-degree angle lens. With ultrasonographic guidance, the endoscope is passed transcervically into the extracoelomic cavity (chorionic cavity) without disturbing the amnion (Figs. 1 and 2). A complete examination of the embryo or fetus includes visualization of the head, face, dorsal and ventral walls, limbs, umbilical cord, and yolk sac. The average length of time for this procedure is 5 minutes, and the success rate for visualization of the fetus is above 95%. Dumez[15] has reported a similar success rate. He has also performed embryoscopy, undertaken to rule out head and limb anomalies, in >50 continuing pregnancies. In his early attempts two pregnancies were lost, but in subsequent work no adverse outcome was noted. In our experience the inadvertent perforation of the amnion occurred most frequently at or beyond 12 weeks' gestation, when the chorion and amnion were fused. It should be emphasized that overall relatively few ongoing pregnancies have so far been investigated, but this is expected to change with further improvement in the technique.

Applications

Embryoscopy can be performed as early as three conceptual weeks (5 weeks' menstrual age) and continued throughout the first trimester. The procedure is therefore particularly suitable for the documentation of developmental events of the embryo and fetus and for the diagnosis or reconfirmation of malformations.[16]

The fetal face and head can be examined from six menstrual weeks of gestation on (Fig. 3). Gross malformations such as anencephaly and acrania are therefore likely to be diagnosed by embryoscopy. Hypotelorism, hypertelorism, and the absence of one or both eyes are other anomalies that should be easily visualized by direct examination of the fetus. The same holds true for ventral wall defects (Fig. 4). We have diagnosed a case of omphalocele at 10 weeks' gestation by embryoscopy. Limb deformities are particularly well visualized. We have also diagnosed polydactyly at 11 menstrual weeks of gestation, and it appears feasible to diagnose many other limb malformations as well, because of the clear delineation of limb anatomy on direct visualization. Thus embryoscopy can serve as a primary diagnostic tool for congenital anomalies in the first trimester or for confirmation of ultrasonographically suspected anomalies.[16]

Furthermore, from a conceptual point of view, embryoscopy will be of increasing importance to general human embryology. Much of our knowledge of early human development is based on the investigation of human abortuses or analogies drawn from animal research. It is conceivable, however, that the very same abnormality that causes a miscarriage could affect fetal growth and development as well, thereby somewhat

limiting the validity of the former approach. On the other hand, stages of embryonic development in animals are not necessarily representative of human development, thereby limiting the validity of the latter approach. Embryoscopy visualizes the human embryo in vivo, unaffected by any abnormality of the uterine or hormonal environment and representative of the intrinsic capability of a given fetus for early development.

In this context a major question awaiting elucidation is the unclear role of the yolk sac in early human development. The yolk sac provides blood cell precursors, gonadocytes, and epithelia of the digestive and respiratory tracts and has been demonstrated to be structurally altered when exposed to high glucose concentrations in embryo-culture experiments. It has been suggested therefore that the yolk sac could play an essential role in the pathogenesis of congenital anomalies among fetuses of diabetic mothers.[17-20] Direct observation of the yolk sac by embryoscopy, as well as aspiration of its contents for laboratory analysis, could enhance our understanding of human malformations considerably.

Last, first-trimester diagnosis and treatment of genetic diseases by embryoscopy are very intriguing. Embryonic organ-tissue biopsy and/or embryonic blood sampling certainly appear to be within reach. Rapid progress has also been made in recent years toward the concept of human cell and gene therapy. Even though human gene therapy has not yet been approved for clinical trials, we are at the threshold of an era in which this new therapeutic approach will probably be used in the treatment of currently incurable diseases. Obviously, the in utero application of this technology would be limited to serious genetic diseases that produce irreversible damage by the time of birth. At present, the only human tissue that can be used effectively for gene or cell transfer is bone marrow. It is expected, however, that more will be learned in the future about how to package the DNA and to make it tissue specific. It would then be feasible to use the intravenous route for injection of genetic material and for access to the embryo and its circulatory system.

The potential feasibility of the above approach has been tested by Kantoff et al.[21] They demonstrated expression of the human adenosine deaminase (ADA) gene in the blood cells of irradiated monkeys that were reinfused with their own bone marrow cells after the cells had been treated in vitro with an ADA retroviral vector. The first attempts at postnatal human therapy of ADA deficiency are at advanced stages. Other genetic diseases, particularly those that affect the brain (e.g. Lesch-Nyhan disease), will require in utero intervention to be effective. Because in utero transplantation of donor tissue might become necessary to achieve this goal, embryoscopy could be an invaluable access tool to the early embryo-fetus, which would allow for graft acceptance by a "naive" immune system.

Embryoscopy therefore is expected to have a major impact on fetal medicine in the years to come. Prenatal diagnosis and therapy will change considerably, with more emphasis placed on the first-trimester fetus. Undoubtedly, many ethical, legal, and regulatory questions will have to be addressed before the full potential of embryoscopy is realized. The responsibility for the judicious use of this powerful technology for prenatal intervention will have to be shared by the scientific community and a well-informed public.

Maternal and fetal outcome after breast cancer in pregnancy

Donna Zemlickis, BSc,[a] Michael Lishner, MD,[b] Pamela Degendorfer, MA,[b] Tony Panzarella, MSc,[b] Bonnie Burke, BSc,[a] Simon B. Sutcliffe, MD,[b] and Gideon Koren, MD[a]

Toronto, Ontario, Canada

We compared 118 women with breast cancer (119 pregnancies) with 269 nonpregnant control subjects matched on important prognostic factors. The distribution of breast cancer stages among the 118 pregnant women was compared with that among 5115 cases of breast cancer in women of reproductive age. Fetal outcome was compared with that of a control group matched for maternal age. Women having breast cancer in pregnancy were 2.5 times more likely to have metastatic disease (95% confidence interval 1.1 to 5.3) and had a significantly lower chance of having stage I disease ($p = 0.015$). Survival of pregnant women did not differ from that of the controls. Birth weights of babies born to women with breast cancer were significantly lower than those of control babies after gestational age was adjusted for (3010 ± 787 vs 3451 ± 515 gm, $p = 0.016$). The two stillbirths in 85 pregnancies that continued to term (2.4%) was not statistically different from the 1.1% rate for Ontario. We analyzed all 223 births occurring in women who had any form of cancer in the same hospital during the same 30 years. There were 10 stillbirths among these 223 cases (4.4%), significantly more than expected in Ontario ($p < 0.0005$; relative risk of 4.23 with 95% confidence interval 2.0 to 7.8). Our data suggest that pregnant women are at a higher risk of presenting with advanced disease because pregnancy impedes early cancer detection. (AM J OBSTET GYNECOL 1992;166:781-7.)

Key words: Pregnancy, breast cancer, fetus, chemotherapy, survival

Cancer occurring during pregnancy poses a very difficult challenge to the woman, her family and her physicians, because cancer therapy may be detrimental to the unborn baby. Equally difficult, postponement of therapy may theoretically decrease her chances of survival. Traditionally, cancer during pregnancy was believed to be associated with poor prognosis and an increased risk of harm to the fetus.[1-3] This impression may have led to unnecessary fear on the part of the patient and her physician; conversely, some recent studies have indicated that the pessimistic view is not based on objective data.[4-7]

Breast cancer is the most common tumor in women of reproductive age; 3% of breast cancer occurs in pregnancy.[8,9] Because of the relative rarity of breast cancer in pregnancy, there is a paucity of information on the effects of pregnancy on the course of breast cancer and the effect of the disease and its therapy on pregnancy outcome.

Using a large data base accumulated for >30 years in an oncologic hospital in Toronto, we undertook a historic cohort study to assess the effects of pregnancy on the diagnosis and course of breast cancer and the impact of the disease and its treatment on fetal outcome.

Material and methods

Princess Margaret Hospital is an oncologic hospital in Toronto serving the province of Ontario. It maintains a computerized data base of patient records dating back to 1958; this data base was used to identify the patients for the study. Patients were recruited from 1958 to 1987. The Motherisk Program, based at the Hospital for Sick Children in Toronto, is an antenatal counseling service for women exposed to drugs, chemicals, and radiation during pregnancy and lactation.

All women with histologically proven breast cancer

in pregnancy registered in the data base between 1958 and 1987 were identified. On the basis of the assumption that cancer would be present for some time before it could be diagnosed, the time frame for inclusion in this analysis selected women who were pregnant within 9 months before or 3 months after first treatment. Because the date of diagnosis was often not recorded in the data base, we used the date of first treatment as the reference date, assuming that there would be minimal delay from the time of diagnosis to treatment (surgical, radiologic, or medical). Extreme cases included in our study were women who were delivered 9 months before first treatment and women who conceived 3 months after the last day of their first treatment.

Potential cases identified by the computer were further screened by examination of their charts to confirm that pregnancy and breast cancer occurred according to the time frame defined and to reject any patients who had an ectopic pregnancy.

To study the potential effects of pregnancy on women's survival, we matched women having breast cancer in pregnancy to nonpregnant women with the tumor. For each case an attempt was made to identify three matching controls in the data base according to these criteria: (1) The control woman could not have been pregnant within 15 months prior to 9 months after first treatment. A 6-month addition on both sides of the time frame ensured that a pregnancy would have no effect on the cancer and that the cancer would have no effect on a pregnancy. (2) Controls had the same stage of breast cancer as the cases at diagnosis. The clinical stage was used for both cases and controls when available, and pathologic evidence was used when the clinical stage was not recorded (Table I). (3) Controls were within 2 years of the ages of cases at diagnosis. (4) Controls had diagnosis or first treatment within two calendar years of the matched case. Type of treatment was not explicitly matched; however, strict hospital protocol dictated that patients of the same age, stage, and calendar year of diagnosis would be given the same treatment. The validity of this assumption was verified in a random sample of 10 pregnant women and 20 controls, which showed identical treatment in 16 (80%) and very similar treatment in the remaining 4 (20%) (minor changes in protocol).

Details of the breast cancer, TNM system staging, and date of diagnosis were recorded for the cases and controls. All cases and controls were rated by the TNM system of 1987.[10] Charts with an ambiguous TNM rating were assessed from the pathology reports and clinical workup. Table I illustrates the staging method.

Dates and types of treatment, including whether treatment was delayed because of the pregnancy, were also obtained. For obstetric information, date of conception, gestational age at diagnosis and first treatment, complications in pregnancy, if any, and pregnancy outcome were recorded.

To compare the distribution of disease stages on diagnosis of breast cancer in pregnancy with that of nonpregnant women of reproductive age (≤47 years) registered in Princess Margaret Hospital, the Princess Margaret Hospital data base was used, in which 3949 cases had an identifiable stage and an additional 1166 cases were identified as clearly not being stage IV (either I, II, or III) for the same calendar years.

For pregnancies that continued to term or resulted in stillbirth, birth records were requested from the delivering hospital. For live births, sex and birth weight of the infant were recorded, as well as gestational age at delivery, type of delivery, Apgar scores, fetal complications, and congenital anomalies. In the case of a cesarean section, the reason for choosing this method was recorded. For intrauterine death, date of diagnosis and autopsy results were collected.

Fetal outcome after maternal breast cancer as compared with that of babies born to women attending the Motherisk clinic during the first trimester after exposure to drugs, chemicals, or radiation during pregnancy. For this analysis each mother with breast cancer who had a live birth was matched with a mother of similar age who was exposed to nonteratogenic drugs or chemicals.

Statistical analysis. Kaplan-Meier[11] estimates were used to produce survival curves, and the Mantel-Haenszel log rank test[12] was used to compare the cause-specific survival of cases and their matched controls. The χ^2 test was used to compare the distribution of tumor stages on diagnosis between the cases and the nonpregnant women of reproductive age having breast cancer and registered in the data base. Fetal outcome values between the study and control groups were compared by two-sided Student *t* test for unpaired results. When birth weight was adjusted for the effect of gestational age, analysis of covariance was applied. The odds ratio was used to estimate the relative risk that a pregnant woman with cancer would have advanced disease[13] and that a pregnant patient with cancer would have a stillbirth. The observed number of stillbirths was assumed to follow a Poisson distribution. Statistical analysis was performed with SAS version 5.1 and Minitab release 6.1.1.

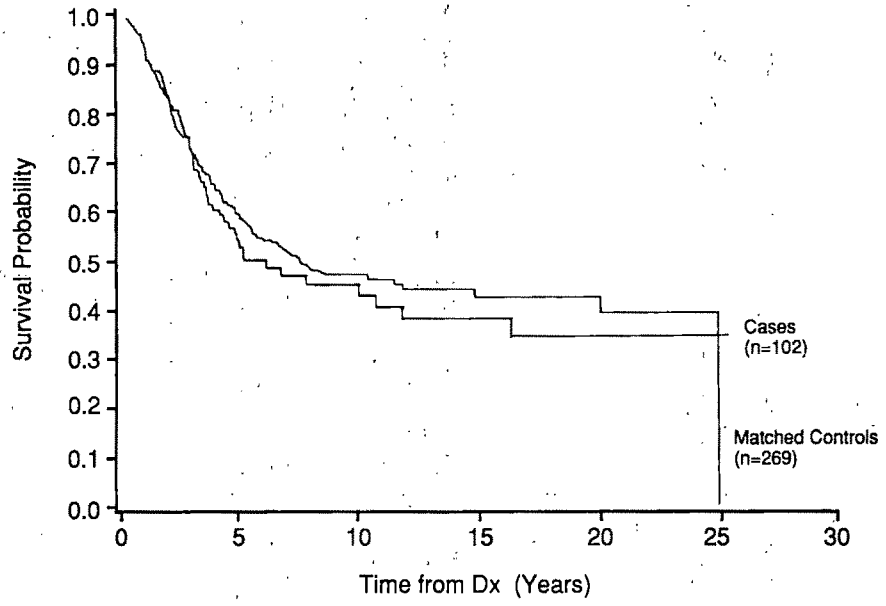

Fig. 1. Kaplan-Meier cause-specific survival curve for breast cancer comparing women who were pregnant and had breast cancer ($n = 102$) against matched nonpregnant controls ($n = 269$), $p = 0.6$.

Results

There were 118 cases of breast cancer and pregnancy identified in the 30 years analyzed in our study. One woman had two pregnancies, both of which fit in the time frame of the study, resulting in a total of 119 pregnancies in 118 women. The mean age of pregnant patients with breast cancer was 32.9 ± 5.13 years at diagnosis. The median age was 33 years (range 23 to 47). Of the 119 pregnancies, 14 women were diagnosed with breast cancer before conception, 42 during pregnancy, and 55 after delivery or termination of the pregnancy. In eight cases when conception occurred relative to diagnosis was not recorded.

Of 118 women, 22 had surgery as first treatment, five received radiation, three received chemotherapy, 45 had surgery and radiation, 20 had surgery and chemotherapy, two received radiation and chemotherapy, and 21 received all three. Of the women with diagnosis before or during the pregnancy ($n = 56$) who received treatment during the pregnancy ($n = 42$), 24 had surgery, five radiation, two chemotherapy, three both surgery and chemotherapy, and eight both surgery and radiation. Of this group of women, there were 16 elective abortions, two miscarriages, and 38 live births. Sixteen women chose to delay the recommended treatment until after delivery or termination (two of whom had surgery and delayed chemotherapy). Only five babies were exposed in utero to cancer chemotherapy, three of them during embryogenesis. These three women chose to terminate the pregnancy.

There were 269 matched controls identified for 102 cases. Three controls per patient could not always be obtained because the matching criteria were selective enough that the data base did not always contain three matches per case. For those women who had matched controls, the distribution of types of treatment between cases and controls was not statistically different ($p > 0.75$). There were 16 cases that did not have matched controls. Six patients were diagnosed with breast cancer in the late 1950s or early 1960s and could not be matched because computer records of that time contained ambiguous staging codes. Seven patients had no matches because the disease could not be properly staged, and the remaining three had no matches in the data base. Review of these 16 charts did not reveal any systematic features that would explain why these patients could not be matched.

A Kaplan-Meier plot reveals that survival did not differ statistically between the pregnant and nonpregnant women ($p = 0.6$, Fig. 1). At the time of the study, 52 of the cases had died of breast cancer, whereas the remaining 50 either were alive or had died of other causes. In the control group 129 patients died of breast cancer.

Fig. 2 compares the subgroup of patients who were diagnosed with breast cancer before conception or during pregnancy ($n = 44$) with their matched controls ($n = 118$), showing virtually identical survival over 15 years ($p = 0.05$).

For women who were diagnosed with breast cancer during pregnancy and maintained the pregnancy until delivery ($n = 32$), five were diagnosed during the first trimester, 11 during the second, and 16 during the third. Fig. 3 shows no statistically significant difference

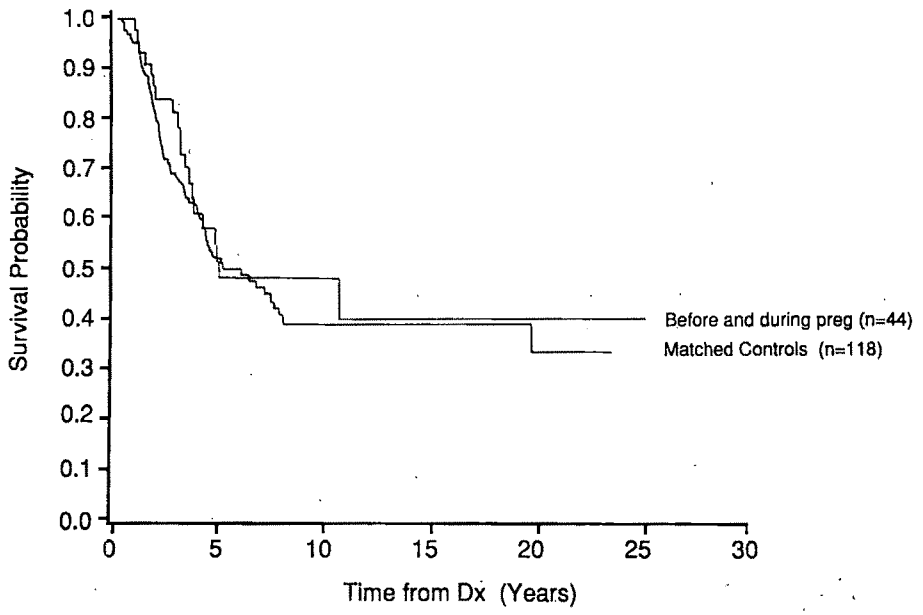

Fig. 2. Kaplan-Meier cause-specific survival curve for breast cancer comparing women whose diagnosis was before or during pregnancy ($n = 44$) against their nonpregnant matched controls ($n = 118$), $p = 0.5$.

in survival among the three trimesters ($p = 0.8$). Fig. 4 compares the survival of women who maintained the pregnancy until delivery ($n = 32$) with that of those whose pregnancy terminated either electively ($n = 9$) or spontaneously ($n = 1$). No statistically significant difference was found ($p = 0.5$). Women who delayed treatment until after delivery did not have a worse prognosis than their matched controls (11 cases and 28 controls, $p = 0.05$); however, because of the small sample sizes in Figs. 3 and 4, the power is low.

Among 111 cases with available staging, 51 (45.9%) had stage I disease at diagnosis, 44 (39.6%) stage II, six (5.4%) stage III, and 10 (9.0%) stage IV. The cause-specific survival by stages is shown in Fig. 5. A statistically significant difference in survival was found among the stages ($p = 0.001$).

Through the computerized data base, we identified 3949 women of reproductive age (≤47 years) in the same time period (1958 through 1987) for whom complete staging was available and an additional 1166 women for whom partial information could confidently rule out stage IV disease.

Of the 3949 women, 2288 (57.9%) were diagnosed with stage I disease, 1293 (32.7%) with stage II, and 169 (4.3%) with stage III. There were 199 women diagnosed with stage IV disease out of 5115 eligible cases (3.9%). This distribution is statistically significantly different from that of the pregnant women ($0.025 < p < 0.05$). After analysis by individual stage and adjustment for multiple comparisons (Bonferroni method), a statistically lower number of women diagnosed with stage I disease in the pregnant group was found as compared with the data base ($p = 0.015$). Similarly, after we adjusted for multiple comparisons, there was a statistically higher proportion of women diagnosed with stage IV disease in the pregnant group compared with the data base ($p = 0.013$). The relative risk of having stage IV disease in pregnancy was 2.5 (95% confidence interval 1.1 to 5.3).

Fetal outcome. Of the 119 pregnancies, 22 were terminated by elective abortion and 12 by miscarriage, there were 85 deliveries. Of the 85 deliveries, there were 83 live births and two stillbirths. Twenty-one of the deliveries were by cesarean section; 18 of these were performed to allow initiation of therapy for breast cancer, whereas the remaining three were for non-cancer-related obstetric difficulties. We were able to obtain 62 obstetric records from the delivering hospitals and one autopsy report. The remaining delivery records could not be obtained because some charts did not indicate the delivering hospital or the delivering hospital had destroyed old birth records. In some cases the delivering hospital refused to release confidential documents because of strict hospital guidelines. A summary of the available information regarding fetal outcome is presented in Table II.

There was a statistically lower mean birth weight for babies of mothers with breast cancer when compared with their matched controls ($p = 0.002$). Similarly, they had a statistically shorter mean gestational age ($p = 0.006$) because of a significantly higher proportion of preterm deliveries ($p = 0.003$).

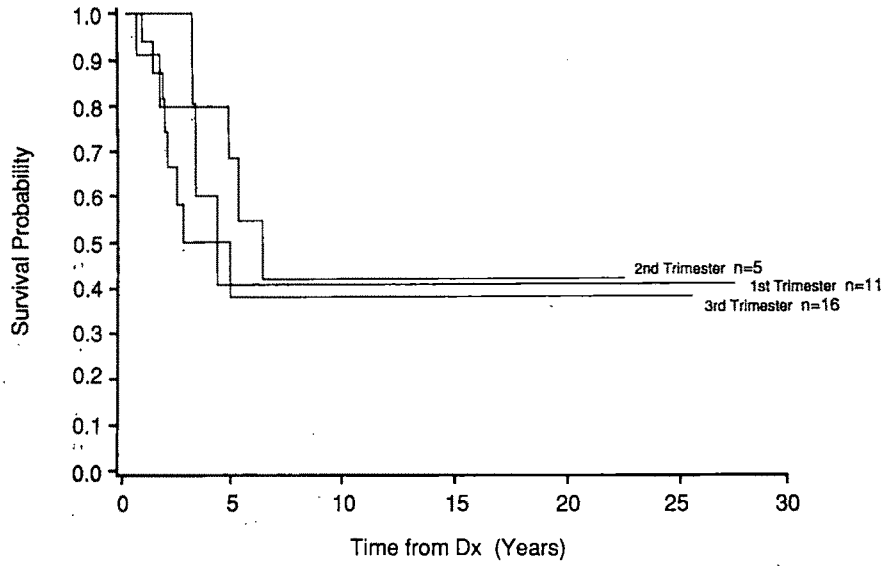

Fig. 3. Kaplan-Meier cause-specific survival curve for breast cancer comparing survival for pregnant women with diagnosis during first (n = 5), second (n = 11), and third (n = 16) trimesters, p = 0.8.

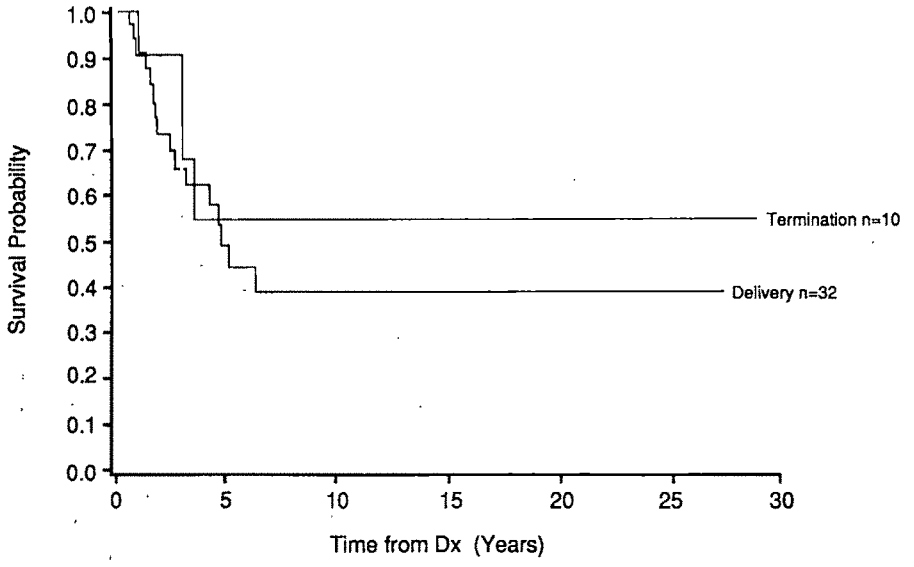

Fig. 4. Kaplan-Meier cause-specific survival curve for breast cancer comparing women who were delivered (n = 32) against those whose pregnancy was terminated (n = 10), p = 0.5.

To assess whether the lower birth weight in babies of cancer patients was due to a greater proportion of premature births or whether the babies were small for gestational age, an adjustment for gestational age was performed by analysis of covariance. This difference was still statistically significant (p = 0.016).

The ratio of stillbirths to live births in our study (2/85, 2.4%) appears larger than the general figure in Ontario (11.1 stillbirths per 1000 total births[14]); however, this difference was not statistically significant. To further verify whether this tendency represents a true risk for stillbirth, we analyzed all 223 births occurring in women who had any form of cancer at Princess Margaret Hospital during the same 30 years. There were 10 stillbirths out of the 223 deliveries, a significantly greater ratio than in the population of Ontario ($p < 0.0005$). This stillbirth rate represents a 4.23 relative risk (95% confidence interval 2.0 to 7.8).

Comment

Because the occurrence of breast cancer during pregnancy is relatively rare (3% of all breast cancers), it is highly unlikely that prospective trials will ever be large enough to assess the effect of breast cancer and its

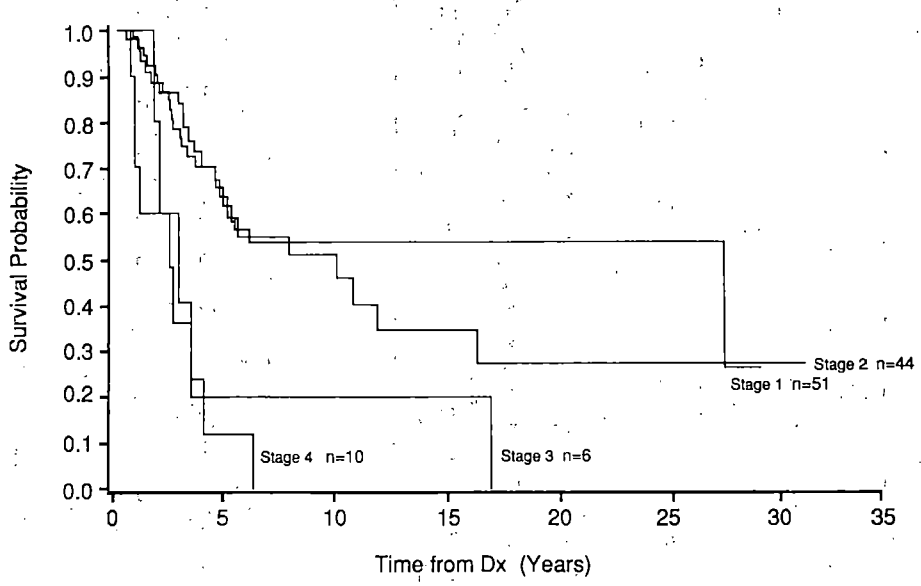

Fig. 5. Kaplan-Meier cause-specific survival curve for breast cancer of pregnant women by stage: stage I *(1)*, $n = 51$; stage II *(2)*, $n = 44$; stage III *(3)*, $n = 6$; stage IV *(4)*, $n = 10$ ($p = 0.001$).

treatment on maternal and fetal outcome. To date, most available studies have analyzed the effect of pregnancy by comparing the course of breast cancer in pregnant women with that in a cohort of unmatched controls, thus carrying a risk of bias because of unbalanced prognostic factors.[7, 15, 16] The few studies that used a case-control analysis comprised a small number of patients.[6, 17-19] We found no statistically significant difference in cause-specific survival between pregnant and nonpregnant women matched by age, stage, and year of diagnosis. However, our data reveal that a pregnant woman has a 2.5-fold higher risk of being diagnosed with metastatic breast cancer and a decreased chance of diagnosis of stage I. Because the prognosis of metastatic breast cancer is poor (Fig. 5), this observation means that pregnancy per se poses a risk to women with breast cancer. Similar findings have been suggested by Clark and Reid,[4] Nugent and O'Connell,[7] Ribeiro et al.,[16] and Petrek et al.[20] However, none of these studies used matched controls to substantiate their hypotheses.

Torres and Mickal[21] and Donegan[22] have suggested that during pregnancy the tumor is stimulated by the elevated estrogen levels, implying that the tumors are estrogen receptor positive. However, it has been shown that young women, pregnant or not, usually have estrogen receptor–negative breast cancer.[7] Estrogen receptor–negative tumors have a biologically aggressive course and carry a poor prognosis.[23] Thus it is theoretically conceivable that pregnancy, with its hormonal stimulation, should not affect the course of the disease. This suggestion is supported by the observation that, after they were matched for tumor stage, our pregnant patients had survival identical to that of the nonpregnant controls. Furthermore, termination of pregnancy was not associated with improved survival.

Our data suggest that pregnant women are at a higher risk of presenting with advanced disease because pregnancy impedes early detection. During pregnancy a woman's body undergoes substantial physiologic changes, including enlargement of the breasts, that make it more difficult to notice small lumps that forewarn of cancer.[24] It is probable that many women and possibly their physicians relate findings consistent

with breast cancer to pregnancy-induced engorgement. It has been reported that the average delay from first symptoms to treatment exceeds 5 months.[6]

A pregnant woman may wish to delay her treatment for fear of the effects on the unborn baby. Among the regimens used in the treatment of breast cancer, chemotherapy has by far the highest likelihood of adversely affecting the baby during embryogenesis.[25, 26] The effects of general anesthesia and surgery on the fetus have been investigated by several researchers, and unless complications occur (e.g., shock, hyperthermia), they do not appear to increase fetal risk.[27, 28] Radiotherapy has the potential of causing irreversible harm to the fetus when the fetal dose is >10 rad; however, when radiation is directed to the breast, the fetal dose is lower than the teratogenic range by several orders of magnitude.[29] In our study we found no malformations either in women who delayed treatment or in those who did not delay treatment. However, our cohort was not delivered of babies who were exposed to chemotherapy during embryogenesis, when major malformations would occur. Babies exposed to cancer chemotherapy later in pregnancy do not appear to have a higher risk for dysmorphologic features.[26, 30]

Children born to women with breast cancer were significantly more likely to be preterm, mainly because elective cesarean sections were done more often to allow earlier start of cancer therapy. Of importance, our data are the first to document small birth weight for gestational age associated with breast cancer, which may be explained by the disease itself and by its treatment. The higher rate of stillbirth in pregnancy further suggests suboptimal intrauterine conditions; the association between small birth weight and stillbirth has long been recognized.[31]

Because the risk of metastatic disease is higher during pregnancy, it is important that pregnant women are instructed to perform regular breast self-examinations or that physicians caring for them perform the examinations during prenatal visits, with particular attention to any changes not consistent with pregnancy. Although breast cancer screening and treatment have advanced in the 30 years covered by this study, we cannot dismiss the importance of our results.

Because of the higher risk for stillbirth and small birthweight, women with breast cancer should undergo close follow-up by a high-risk obstetric unit to define the optimal time of delivery.

Early menopause in long-term survivors of cancer during adolescence

Bethesda and Rockville, Maryland, Emeryville, California, New Haven, Connecticut, Iowa City, Iowa, Kansas City, Kansas, Houston, Texas, and Pittsburgh, Pennsylvania

OBJECTIVE: We attempted to investigate the risk of early menopause after treatment for cancer during childhood or adolescence.

STUDY DESIGN: We interviewed 1067 women in whom cancer was diagnosed before age 20, who were at least 5-year survivors, and who were still menstruating at age 21. Self-reported menopause status in survivors was compared with that in 1599 control women.

RESULTS: Cancer survivors, with disease diagnosed between ages 13 and 19, had a risk of menopause four times greater than that of controls during the ages 21 to 25; the risk relative to controls declined thereafter. Significantly increased relative risks of menopause during the early 20s occurred after treatment with either radiotherapy alone (relative risk 3.7) or alkylating agents alone (relative risk 9.2). During ages 21 to 25 the risk of menopause increased 27-fold for women treated with both radiation below the diaphragm and alkylating agent chemotherapy. By age 31, 42% of these women had reached menopause compared with 5% for controls.

CONCLUSION: Treatment for cancer during adolescence carries a substantial risk for early menopause among women still menstruating at age 21. Increasing use of radiation and chemotherapy, together with the continued trend toward delayed childbearing, suggests that these women should be made aware of their smaller window of fertility so that they can plan their families accordingly. (AM J OBSTET GYNECOL 1992;166:788-93.)

Key words: Menopause, childhood cancer, radiation, alkylating agent, ovarian failure, follow-up studies

Once bleak, the outlook after diagnosis of cancer during childhood or adolescence has improved greatly in the last 20 years. Five-year relative survival rates in the United States are nearly 90% after Hodgkin's disease and 73% for acute lymphocytic leukemia diagnosed during childhood.[1] However, the toxic side effects of successful therapy mean that childhood cancer survivors face the prospect that the cancer could still adversely affect their lives, including their fertility.

In adults cancer treatment significantly reduces reproductive potential. Radiation to the gonads and chemotherapy, especially with alkylating agents, have been linked to gonadal dysfunction, primary and secondary amenorrhea, and azoospermia.[2-6] The probability of amenorrhea increases with age at treatment; older women are more likely than younger women to cease menstruating permanently.[2, 4] Reports of primary amenorrhea,[7, 8] severely damaged ovaries on autopsy,[9] altered timing of menarche,[10-12] and abnormal endocrine values in early adolescence after leukemia[11, 12] show the susceptibility of the prepubertal ovary to some level of damage from cancer therapeutic agents. On the other hand, an analysis of the effects of cyclophosphamide highlighted the resistance of the prepubertal ovary to damage relative to older girls and boys.[13]

No study has yet examined the risks for early menopause after cancer treatment during childhood or adolescence where the effects of different agents could be separated. As part of an interview study of survivors of all types of childhood or adolescent cancer, we examined several questions relating to the risk for early menopause. Specifically we sought to measure the pres-

ence and extent of excess risk, to see whether the risk declined with time since treatment, and to examine the influence of different types of treatment on early menopause.

Patients and methods

Identification of subjects. Five cancer registries identified survivors and controls as described elsewhere.[14] Each registry identified all former cancer patients who met the following requirements for eligibility: a histologically diagnosed malignant neoplasm (or clinically diagnosed central nervous system neoplasm); first diagnosis from 1945 through 1974; 5-year survival after diagnosis at <20 years of age, and survival to ≥21 years of age or more by December 31, 1979. For this report we assembled a group of female controls who had survived to ≥19 years of age as of December 31, 1979, and who were at least age 21 years at interview by selecting up to two full siblings or half siblings closest in age to the survivors in our study.

We defined the age at cohort entry as the age at which a woman survived 5 years beyond diagnosis or reached age 21, whichever was later. For instance, a woman diagnosed at age 19 became eligible for cohort entry at age 24. Survivor cohort is defined as those members of the entire survivor population who were menstruating at the age of cohort entry (n = 954; Table I). The control cohort consisted of all control women who were still menstruating at age 21 (n = 1596; Table I). Nineteen women (18 survivors and one control) never menstruated and are not included in the analysis.

Data collection. Interviews were conducted by trained interviewers between 1980 and 1983 and lasted 45 to 60 minutes. Next-of-kin proxies were interviewed for 12% of survivors and 4% of controls. The most frequent reason for use of a proxy was death of the subject. Ninety-one percent of both groups agreed to be interviewed. At follow-up, 10% of the survivors and 1% of the controls had died. Survivors were aged 32.3 years on average at follow-up, and diagnosis had occurred on average at age 13.6. Controls averaged 33.0 years old at follow-up.

The questionnaire covered demographic and social characteristics and medical, reproductive, and menstrual histories. Each woman was asked her age at the time of her first menstrual period and whether her menses had started spontaneously. Menstrual status and age at menopause were determined from responses to the questions, "Are you still having menstrual periods?" and "What age did you have your last menstrual period?" At the end of the survivor's interview, permission was sought to locate medical records, including investigations of infertility, and to contact the siblings closest in age. A nearly identical interview was conducted with controls. Information on the survivor's tumor and treatment was abstracted from the tumor registry's record and other hospital records. The information abstracted included site and dose of radiotherapy, names of individual chemotherapeutic agents, but not total dose or number of cycles.

Table I. Women grouped according to menopausal status at follow-up

	Survivors	*Controls*
Women who became menopausal before they were eligible for the cohort	94	2
Women who became menopausal after cohort entry but before the end of follow-up	123	222
Women who were still menstruating at the end of follow-up	831	1374

Entry into the cohort occurred at age 21 or at 5-year survival, whichever came later.

Each woman's report of whether she was still having menstrual periods became our definition of menopause. In this paper we do not consider the issues of secondary amenorrhea or temporary cessation of menses, nor do we deal with menstrual problems or whether menopause was natural or the result of surgery.

Survivors were classified by treatment received; many had had only surgical treatment. For some, surgery meant immediate menopause; for instance, a total abdominal hysterectomy for a malignant ovarian tumor. Radiation was categorized according to whether it was administered above or below the diaphragm; chemotherapy was divided into alkylating or nonalkylating types.

Statistical methods. Standard contingency table methods, including χ^2 tests, were used to analyze associations between characteristics of interest and menopause.

Risks were calculated as the number of events (women reaching menopause) divided by the estimated person-years of follow-up. Relative risks (RR) refer to the ratio of risk in a treated group to that in controls. Associated tests of significance were based on the assumption that hazard rates were constant within 5-year age intervals.[15] This is an open cohort because some women were not at risk at age 21, but became so at later ages when they had first survived treatment for 5 years. Methods of survival analysis were used to estimate the proportion still menstruating among the survivor cohort. Appropriate modifications of the usual actuarial methods of analysis were used.[16, 17] Calculations were carried out with *Epicure*,[18] a package of programs developed for data analysis on the personal computer, and SAS (Statistical Analysis Systems, Inc., Cary, N.C.) for mainframe data analysis. The proportional

hazards model of Cox[19] was not used because hazard ratios changed with age.

Results

Menopause before age at cohort entry. Ninety-four (9.0%) of the 1048 survivors who had commenced menstruating had reached menopause by age at cohort entry; many became menopausal immediately on treatment (Table II). Over half of the 90 women treated for genital cancer were no longer menstruating; treatment for 25 women included removal of the genital organs. All women treated for thyroid cancer, kidney cancer, melanoma, neuroblastoma, or retinoblastoma were still menstruating at entry into the cohort. For other forms of cancer the proportion no longer menstruating ranged from 2% for bone cancer survivors to 10% for survivors of either Hodgkin's disease or non-Hodgkin's lymphoma. Women who were treated with infradiaphragmatic radiation plus alkylating agent chemotherapy were nearly four times more likely to be menopausal than women who had radiotherapy *above* the diaphragm with alkylating agents. The risk of menopause increased significantly with increasing age at diagnosis.

Two of the 1593 controls were menopausal at age 21. One had Down syndrome; she had entered menarche normally, but had very heavy menstrual bleeding that was treated by hysterectomy. The other woman had very irregular periods for 9 years and was taking birth control pills; there was no specific reason for menopause.

RTb + AA, Radiotherapy below the diaphragm plus alkylating agent chemotherapy.

*Menopause rates per 1000 person-years; *n* denotes the number of menopause events; relative risks compare the risk that menopause will occur within that age interval for survivors versus controls and are obtained by dividing the rate for survivors by the rate for controls.

†Significance level of $0.01 < p < 0.05$.

‡$p \leq 0.01$.

Menopause in the survivor and control cohorts. Among women who were still menstruating when they entered the cohort, several interesting relative risk patterns emerged within specific age intervals after cohort entry (Table III). Women diagnosed after age 12 years were significantly more likely to become menopausal than controls during the age interval 21 through 30 years (RR 2.32; CI 1.63 to 3.29). Women diagnosed between ages 0 and 12 were not at greater risk than controls and do not appear in Tables IV and V. Women with Hodgkin's disease had significantly elevated risks of menopause mainly during the first 10 years after

cohort entry (RR 3.35; CI 2.06 to 5.47), especially if treated with radiation below the diaphragm plus alkylating agents (RR 9.57; CI 4.93 to 18.69). The relationship between Hodgkin's disease and treatment is discussed below.

Table IV presents the main findings from the study. The age-specific menopause rate was four times greater (RR 4.32; CI 2.28 to 8.17) for survivors overall than for controls from ages 21 through 25. At later ages the relative risk did not differ significantly overall between survivors and controls. Thus the main excess risk among survivors occurred early.

The menopausal rate for women treated with surgery alone was not significantly different from the rate for controls either overall or at any age interval. For other treatments the risk of menopause relative to controls was high at younger ages and declined as the women aged. Women treated with alkylating agent chemotherapy alone had nine times (RR 9.17; CI 2.67 to 31.49) the rate of menopause of controls. Treatment with radiotherapy alone increased the rate over controls by almost fourfold (RR 3.66; CI 1.34 to 9.99). The greatest increase in risk occurred in women who were treated with radiation below the diaphragm plus alkylating agents (RTb + AA); during their early 20s these women had about 27 times the rate of menopause as controls (RR 27.39; CI 12.42 to 60.35). For some types of therapy, for instance, for radiotherapy alone and RTb+AA, the excess risk persisted into the later 20s though at a lower level. Our data are too sparse to say much about persistence of risk into the 30s.

To see if treatment accounted for the increased risk after Hodgkin's disease (Table III), these women and those with other diagnoses were stratified as to whether the treatment was RTb + AA. The risk of menopause remained high in survivors treated with RTb + AA and much lower in survivors with other treatments, regardless of the type of cancer. Thus the elevated risk for women treated for Hodgkin's disease resulted from their exposure to RTb + AA.

The median age at menopause for women treated with surgery alone between the ages of 13 and 19 was 47 compared with 49 years for controls (Fig. 1). Women treated with RTb + AA reached menopause at a median age of about 32 years (obtained by extrapolation), compared with about 44 years for women treated with radiotherapy alone or other therapies.

The conditional probabilities highlight the strong effect of RTb + AA treatment of adolescent girls on menopause during ages 21 through 30 years (Table V). Women who entered the cohort still menstruating faced about a 40% chance of reaching menopause before age 31; their risk beyond age 30 was unknown, because the last menopause in this treatment group occurred at age 30. The conditional probability of menopause between ages 31 and 40 among women who were menstruating at age 30 was not different among controls and survivors in various treatment groups.

Table IV. Age-specific menopause rates and relative risks* for women who were menstruating at cohort entry grouped according to treatment

	Age interval (yr)			
	21-25	*26-30*	*31-40*	*41+*
Controls (n = 22)

All other treatments§ (n = 10)	3.30	1.99	1.17	—

All women were diagnosed between ages of 13 and 19 years.

*Menopause rates per 1000 person-years. Relative risks compare the menopause rate in each age interval for survivors versus controls; they were obtained by dividing the rate for survivors by the rate for controls and were not calculated if the number of women reaching menopause *(n)* was <3 for any one category.

†Significance level of $0.01 < p < 0.05$.

‡$p \leq 0.01$.

§Includes treatments with nonalkylating agent chemotherapy alone and alkylating agent chemotherapy alone.

Comment

We found that women who survived cancer for which they were treated between the ages of 13 through 19 reached menopause earlier than controls, except for cancer survivors treated only with surgery. This finding applies to women who were menstruating at 21 or as soon as 5 years had passed since diagnosis, whichever was later. An elevated risk of menopause was most pronounced in women who were treated with modern combined alkylating agent chemotherapy and radiation below the diaphragm; however, the higher risk of menopause was also seen in those treated with radiotherapy alone and with alkylating agent chemotherapy alone. The excess risk was highest during the years 21 to 25 and diminished as women aged.

This is the first report to describe the risks associated with different therapies on menstrual functioning in long-term survivors of adolescent cancer. Earlier case reports indicated that pelvic radiotherapy in prepubertal girls can cause both primary and secondary ovarian failure[7]; studies have linked ovarian damage to chemotherapy for childhood brain tumors and possibly

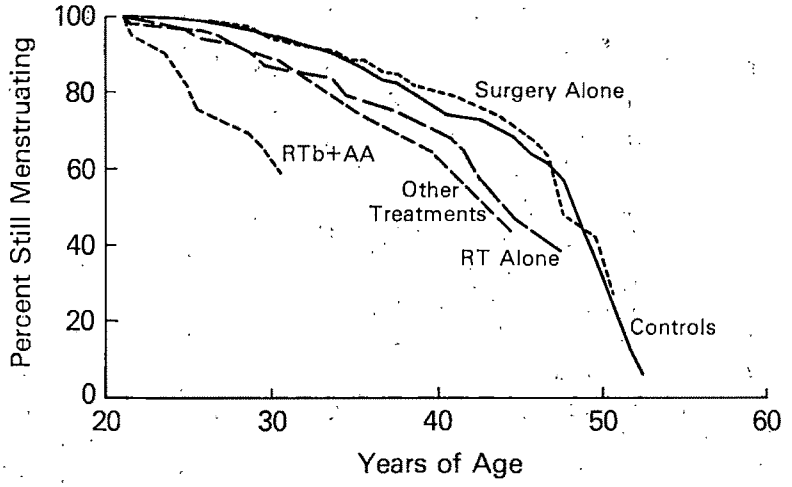

Fig. 1. Proportion still menstruating among cancer survivors diagnosed between ages 13 and 19 grouped by type of treatment received compared with proportion of controls still menstruating (Kaplan-Meier curves). *Probability that a woman who is menstruating at the beginning of each age interval will reach menopause within the interval. *Not calculated* indicates there were no events in 44 person-years. *Numbers in parentheses* are 95% confidence intervals.

after cisplatin administration.[20, 21] Studies of adult women treated for Hodgkin's disease[3-5] showed dose- and age-dependent ovarian failure after treatment with chemotherapy and radiation. In a previous article on the effects of cancer therapy on fertility (defined as the first recognized pregnancy after marriage) in this population, we reported that female fertility was unaffected by treatment with alkylating agents.[14] This finding is consistent with early menopause in women where ovarian failure occurred some time after treatment.

These risks may not apply to adolescents treated today because of better focusing of radiation beams and because shielding of the ovaries is more common. On the other hand, the current widespread use of multiagent regimens for most cancers, including those of childhood, suggests the presence of considerable future risk for early cessation of menses for those treated at susceptible ages.

Diagnosis and treatment before puberty is less damaging to the ovary than treatment after puberty.[13] In our study the small numbers of events in women diagnosed at <13 years of age (n = 13; Table III) made detailed analysis impossible. Among the possible reasons for the apparently reduced risk seen here is bias because of selection, first for the study and then for this analysis. Women diagnosed at <13 years of age had to have reached age 21 years with menstrual function still intact. Treatment before puberty obviously has an adverse impact on ovarian function in this group, because 18 women who were treated before puberty never started menstruating.

Among women who reached menopause at <21 years of age who were not treated with sterilizing surgery (Table II), the increased risk was associated with older age at diagnosis and combined radiotherapy with alkylating agents just as in the survivor cohort.

Although the control group was not chosen to be representative of the general population, the proportion reaching menopause was similar to that reported previously in a cohort of healthy women.[22]

Amenorrhea may occur for many reasons, including hypergonadotropic hypogonadism, resistant ovary syndrome, and poor nutritional status. In this large, multicenter study we did not attempt to confirm menopause by gonadotropin levels. We relied on self-reports, which in other studies have proved to be quite valid, especially where menopause had occurred in the recent past.[23]

If fertility is unimpaired, survivors of childhood or adolescent cancer should not be overly anxious about the success of a pregnancy or the health of a child born after treatment has concluded.[24, 25] However, the same treatments that lead to reduced fertility are also implicated here with early menopause.

This report describes the risks for women who were long-term survivors of childhood or adolescent cancer and who had survived to reach ≥21 years of age. Besides postmenopausal changes leading to osteoporosis and other problems, early menopause obviously influences childbearing. Delayed childbearing became more common in the United States in the late 1980s, and the average age at which women have their first child continues to rise.[26] As multiagent therapies prove to be more effective against cancer, their use is expanding. Our data suggest that early menopause will occur more frequently as girls treated today come into their reproductive years. A woman with a history of adolescent cancer for which she received both radiation and chemotherapy needs to understand her cancer experience and its consequences. Her window of fertility may be much smaller than her sisters'.

We are grateful to former staff members of the National Cancer Institute who contributed to the research, to the staff of the collaborating centers, and especially to the survivors and their families for their cheerful cooperation with this study.

Erythromycin therapy in preterm premature rupture of the membranes: A prospective, randomized trial of 220 patients

Brian M. Mercer, MD,[a] Michael L. Moretti, MD,[a] Rebecca R. Prevost, PharmD,[b] and Baha M. Sibai, MD[a]

Memphis, Tennessee

OBJECTIVES: The use of prophylactic antibiotics in the management of preterm premature rupture of the membranes has not been adequately studied. The purpose of this study was to evaluate the efficacy of oral erythromycin therapy in the prolongation of latency and reduction of infectious morbidity after preterm premature rupture of membranes.

STUDY DESIGN: In this randomized, prospective, double-blind, placebo-controlled study, 220 women at 20 to 35 weeks' gestation were evaluated. Subjects received oral erythromycin 333 mg (n = 106) or indistinguishable placebo (n = 114) every 8 hours from randomization to delivery.

RESULTS: Prolongation of latency was identified with erythromycin therapy (p = 0.02), particularly for those destined to have chorioamnionitis (p = 0.003) and those with oligohydramnios (p = 0.01). No decrease in the incidence of maternal or neonatal infectious morbidity was seen.

CONCLUSIONS: Oral erythromycin delays, but does not prevent, the onset of clinical infection when administered to women with preterm premature rupture of membranes. This regimen does not decrease neonatal morbidity and mortality. (Am J Obstet Gynecol 1992;166:794-802.)

Key words: Preterm premature rupture of fetal membranes, erythromycin, antibiotics, infection

Preterm premature rupture of the membranes is a major cause of maternal, fetal, and neonatal morbidity.[1-3] Neonatal morbidity is mainly related to preterm birth as a result of the short latency from membrane rupture to delivery. Demographic studies have also demonstrated a correlation between preterm premature rupture of the membranes and maternal and neonatal infection, and neonatal sequelae have been demonstrated to increase with maternal infection before delivery.[2-5]

There have been several studies (controlled and uncontrolled) describing the use of antibiotics in the management of patients with preterm premature rupture of the membranes. In these studies demethylchlortetracycline,[6] vaginal nitrofurazone,[7] penicillin, kanamycin,[8] and ampicillin[9, 10] have been evaluated for their efficacy in reducing maternal and neonatal morbidity. Unfortunately, these studies have included heterogeneous groups of patients at various gestational ages with various risk factors. In addition, some of the agents studied are not currently considered appropriate for use during pregnancy.[6, 8] Moreover, these studies have been nonblinded[9, 10] or retrospective[11] or have demonstrated no clinical efficacy.[7]

In a recent prospective, double-blind study the use of parenteral mezlocillin followed by oral ampicillin until delivery was associated with prolonged latency, increased birth weight, and reduced incidences of chorioamnionitis, endometritis, and suspected neonatal sepsis.[12] In addition, a prospective study conducted at this institution by Amon et al.[9] found that the combination of parenteral and oral ampicillin in patients with premature rupture of the membranes was associated with an increased latency period and reduced neonatal infectious morbidity. At the time of submission of this article there are no published randomized studies of the use of erythromycin in patients with preterm premature rupture of the membranes.

The purpose of this prospective, double-blind, placebo-controlled study was to assess whether the use of oral antibiotic therapy in women with preterm premature rupture of the membranes would increase the latency period and reduce the incidence of maternal and neonatal infectious morbidity.

Material and methods

This clinical trial was performed at the University of Tennessee, Memphis, a tertiary care perinatal referral center, from March 1, 1989, to Aug. 1, 1990. The study was approved by the university's institutional review board.

Each woman who was admitted with a history of preterm premature rupture of the membranes had a sterile speculum examination for confirmation of membrane rupture and evaluation of cervical dilatation. Mem-

brane rupture was confirmed by the visualization of amniotic fluid passing from the cervical os or by the presence of a pool of fluid in the posterior fornix that gave positive results with Nitrazine or ferning. Cervical cultures for *Neisseria gonorrhoeae* and *Chlamydia trachomatis* and vaginal cultures for group B streptococci were obtained at the time of initial examination. Digital vaginal examinations were not performed in the absence of advanced cervical dilatation. Gestational age was determined by menstrual history, early clinical examination, or ultrasonographic assessment before 24 weeks' gestation. Fetal heart rate and uterine contraction monitoring was performed for evidence of fetal distress and labor. Blood was drawn for complete blood cell count and C-reactive protein. Ultrasonographic examination was performed for estimation of fetal weight, amniotic fluid assessment, and amniocentesis. Amniotic fluid from amniocentesis was assessed for pulmonary maturity (fetal surfactant index ≥47, lecithin/sphingomyelin ratio ≥2:1 considered mature), Gram stain, culture, and sensitivity. Vaginal pool fluid was sent for pulmonary maturity studies (fetal surfactant index) if amniocentesis was not feasible or was unsuccessful. Catheterized urine was obtained for microscopy, culture, and sensitivity. Women were excluded from study in the presence of the following: membrane rupture of >72 hours' duration, cervical dilatation >4 cm, progressive labor, vaginal bleeding, temperature ≥99.0° F, active infection requiring antibiotic therapy, antibiotic therapy within 1 week before admission, active hepatic disease, erythromycin allergy, cervical cerclage, or a medical condition necessitating delivery. Women with fetuses having intrauterine growth retardation (<10th percentile), congenital anomalies, or evidence of fetal distress were also excluded from randomization. Women requiring parenteral tocolysis for preterm labor on admission were excluded from randomization unless tocolysis was successful.

Consenting women between 20 weeks' and 34 weeks' 6 days' gestation were then randomized. The randomization scheme was generated by computerized random number tables and administered by the inpatient pharmacy at this institution. To reduce the chance of differing gestational ages within the two study groups, randomization was stratified at 30 weeks' gestational age. The enteric-coated erythromycin base and placebo were supplied by Boots Pharmaceuticals (Lincolnshire, Ill.) and packaged by the inpatient pharmacy in indistinguishable plastic wraps. At the time of randomization the patients were assigned by the pharmacist to receive either erythromycin base, 333 mg, or an indistinguishable placebo tablet every 8 hours until delivery. All investigators, patient care givers, and patients were blinded to the randomization scheme until after completion of the study and data analysis.

Subsequent to a minimum of 12 hours of observation, patients not showing evidence of infection, fetal distress, or infection were transferred to the antepartum ward. They were restricted to bed rest with bathroom privileges and were counseled to remain in the hospital until delivery. Digital pelvic examinations were prohibited until such time as a decision was made to allow delivery. Women with immature pulmonary maturity studies (fetal surfactant index <47 or lecithin/sphingomyelin ratio <2:1) received betamethasone, 12 mg intramuscularly for two doses, 24 hours apart. Patients had follow-up with nonstress tests and biophysical profile testing daily for 5 days with subsequent twice-weekly testing if results remained reassuring (defined as a reactive nonstress test or a biophysical score of ≥6/8). The nonstress test was considered reactive if there were two accelerations of 15 beats/min lasting 15 seconds over a 20-minute period. The biophysical profile score was obtained over a 30-minute period with a score of 0 or 2 for each of fetal breathing activity, movement, tone, and amniotic fluid pocket of 2 × 2 cm. Complete blood cell count and C-reactive protein were obtained daily for 5 days and then twice weekly.

In the presence of labor or suspected chorioamnionitis, patients were transferred to the labor unit for continuous maternal and fetal evaluation. Chorioamnionitis was defined as a maternal temperature of ≥100.4° F (in the absence of another identifiable source of infection) plus two of the following additional diagnostic criteria: fetal or maternal tachycardia, uterine contractions or tenderness, or foul-smelling amniotic fluid. Suspected chorioamnionitis was diagnosed when only two of the three diagnostic criteria for chorioamnionitis were met. Parenteral tocolysis was used therapeutically for preterm labor in the absence of clinical evidence of infection. Patients with progressive labor refractory to parenteral tocolysis, abnormal fetal heart rate patterns, nonreassuring fetal testing (nonreactive nonstress test with biophysical profile score ≤4/8), and suspected or frank chorioamnionitis were allowed to deliver. Cesarean delivery was performed for standard obstetric indications. Intravenous ampicillin and gentamicin were administered for intrapartum temperature >100.4° F and continued until the patient remained afebrile for 48 hours. Endometritis was diagnosed in the presence of a persistent temperature of ≥100.4° F with abnormal uterine tenderness, in the absence of another identifiable source of infection.

Neonates were cared for by neonatal subspecialists blinded to the maternal treatment arm. Preterm infants who were delivered >48 hours after membrane rupture and any infant of a mother with intrapartum fever received parenteral ampicillin and gentamicin, pending results of blood cultures and urine Wellcogen testing for group B streptococci; daily complete blood cell count and C-reactive protein testing were also done. Antibiotics were then discontinued if the infant re-

*Three patients lost to follow-up (placebo, $n = 2$; erythromycin, $n = 1$).

mained clinically stable, without hypothermia, elevated C-reactive protein level, or increased or decreased white blood cell count. Neonatal sepsis was diagnosed when the infant appeared clinically infected, and either cultures (blood, urine, or cerebrospinal fluid) were positive or radiographic findings were diagnostic (pneumonia, necrotizing enterocolitis). Suspected neonatal sepsis was diagnosed when clinical findings of sepsis could not be confirmed on microbiologic or radiographic assessment or in the presence of an abnormal white blood cell count or C-reactive protein level in an otherwise healthy-appearing neonate. Infants diagnosed as having suspected or confirmed sepsis received a full course of parenteral antibiotics. Cranial ultrasonographic examinations were routinely performed on all infants weighing <1750 gm and on any infant demonstrating suspicious neurologic findings.

Statistical analysis was performed by a statistician blinded to the study code with the SAS system for elementary statistical analysis (SAS Institute Inc., Cary, N.C.). All patients were maintained within their randomization group for analysis, regardless of compliance and results of cultures performed on admission. Comparative data analysis was performed with Fisher's exact test and the Student t test where appropriate. Life-table analysis with the Wilcoxon statistic was performed for temporal data. A p value of <0.05 was considered statistically significant.

Results

A total of 268 patients were eligible for the study. Eighteen eligible women refused to participate (7.6%), and 30 were not screened (11.2%). The other 220 women were randomized to receive either a placebo ($n = 114$) or oral erythromycin ($n = 106$). Six women did not complete the protocol (four receiving erythromycin), and three of these were lost to follow-up after they left the hospital against medical advice (one receiving erythromycin). Available data from the three women not completing the protocol were included in the statistical analysis. An additional 10 women received ampicillin (seven receiving erythromycin) for urinary tract infection. There were six sets of twins (four receiving erythromycin). Parenteral tocolysis was administered in equal numbers of women in both placebo and erythromycin study groups (59%). Parenteral tocolysis (subcutaneous terbutaline 61.7%, intravenous magnesium sulfate 49.2%, ritodrine 10.9%). There was no difference between the two study groups in the distribution of tocolytic agents used. Two or more tocolytic agents were used in 33.3% of the placebo tocolysis group and in 22.6% of the erythromycin tocolysis group (not significant). Betamethasone was administered to 50.9% of women in the placebo group and 57.5% of women in the erythromycin group.

Table I compares the demographic distribution and clinical findings between the erythromycin and placebo groups. There were no significant differences in any of the parameters studied. Fifteen patients had gastrointestinal discomfort (8/15 receiving placebo), but none required discontinuation of the study medication.

Cervical and vaginal cultures were performed in 188 of 220 women on admission (85.5%). No significant differences were identified with respect to carriage of *N. gonorrhoeae, C. trachomatis,* or group B streptococci in the placebo and erythromycin groups (8.2% vs 6.6%, 16.3% vs 23.0%, and 15.4% vs 18.4%, respectively). Amniocentesis was attempted in 113 patients (53.6%) and was successful in 97 (44.1%). Of the remaining patients, two refused the test and 100 had severe oligohydramnios precluding the procedure. The incidence of positive amniotic fluid cultures in the placebo group (17.9%) and erythromycin group (18.4%) was similar.

Table II summarizes maternal morbidity related to premature rupture of the membranes. The incidence of clinical abruptio placentae was surprisingly high in both groups. No differences in the incidences in clinical chorioamnionitis or endometritis were identified.

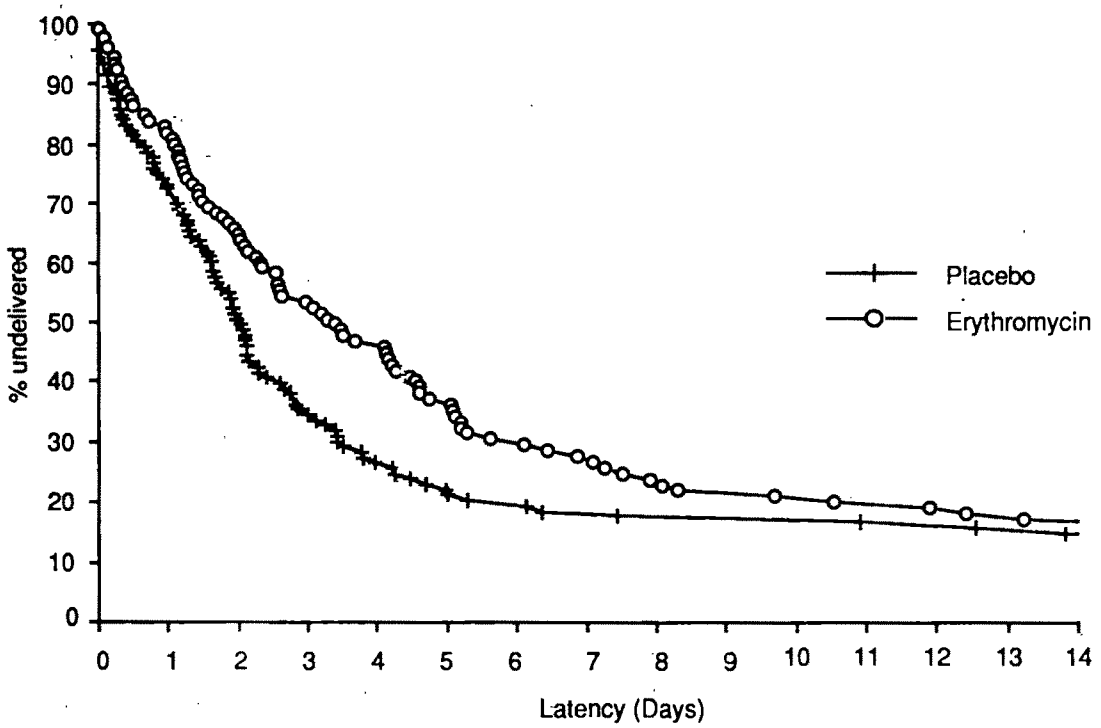

Fig. 1. Latency from randomizat on to delivery for patients receiving erythromycin base or placebo.

Table III. Women remaining undelivered on each of the first 7 days after randomization

	Women (No.)

*One patient lost to follow-up.

Fig. 1 displays the survival curve for latency from randomization to delivery. Significant prolongation of latency from randomization to delivery (p = 0.02) was identified with erythromycin therapy. Significant differences in latency were noted in the first week after randomization (Table III). Subsequent to this time, no differences in latency were identified.

Fig. 2 displays the survival curves on the basis of the development of subsequent chorioamnionitis. The latency curve was significantly prolonged for patients with chorioamnionitis (p = 0.003), but statistical significance was not reached for the suspected chorioamnionitis group (p = 0.10) or for those not having infection (p = 0.43).

Fig. 3 displays survival curves for women with positive amniotic fluid cultures, negative cultures, and for those who had no amniocentesis because of oligohydramnios. Significant differences in latency period with erythromycin were noted only in those women not undergoing amniocentesis (p = 0.01). The incidence of chorioamnionitis was 12.5% and 29% for women with negative and positive amniotic fluid cultures with median latencies of 4.16 and 1.84 days, respectively. Chorioamnionitis was seen in 24% of women with oligohydramnios precluding amniocentesis, with a median latency of 2.12 days.

The 220 pregnancies resulted in 226 births (six sets of twins). Outcome data were not available for three infants of women who were lost to follow-up. A male predominance was identified in both groups (erythromycin 55.0%, placebo 58.8%).

Table IV compares perinatal outcome between the two study groups. There were seven stillbirths; however, only two of these occurred in infants weighing >600 gm (both in the placebo group). In addition, there were no significant differences in perinatal morbidity

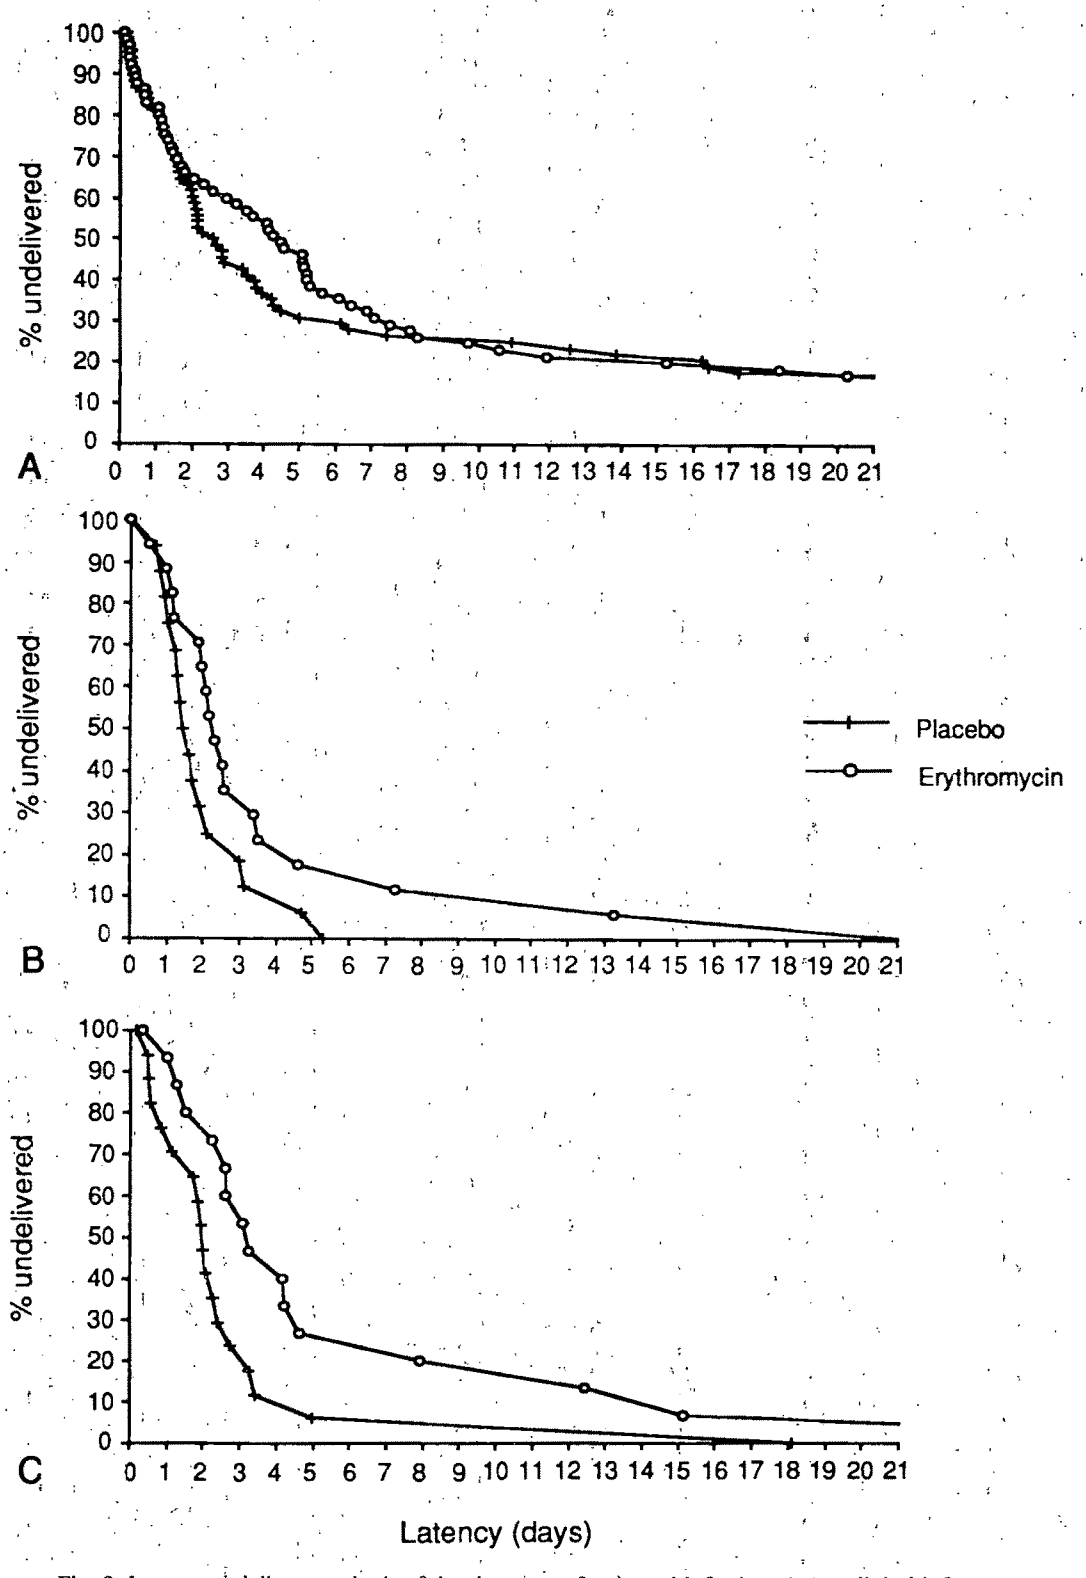

Fig. 2. Latency to delivery on basis of development of maternal infection. **A,** No clinical infection; **B,** suspected chorioamnionitis; **C,** clinical chorioamnionitis.

and mortality between the two groups. There were four cases of congenital pneumonia in the placebo group: Two had positive cultures for group B streptococci, *Enterobacter cloacae* grew in one infant, and one case was diagnosed radiographically after negative cultures.

Bacteria grown from amniotic fluid and early neonatal blood cultures are listed in Table V.

Table IV. Perinatal outcomes

Comment

Several studies have attempted to address the role of antibiotic therapy in the prolongation of pregnancy and reduction of maternal and neonatal infectious outcomes. Unfortunately, these studies have been of small sample size,[9, 10, 12] nonblinded,[9, 10] or retrospective.[11]

In an excellent double-blind prospective evaluation of 85 women reported by Johnson et al.,[12] treatment with intravenous mezlocillin (followed by oral ampicillin until delivery) was associated with an increase in latency to delivery and a decrease in suspected sepsis. A 150% increase in the number of undelivered women was seen after 1 week of therapy. However, sample size was small. Although an increase in mean latency was claimed, median latency was not provided. It is generally accepted that in skewed population curves, such as latency after premature rupture of the membranes, the median is more reflective of population trends.

A prospective evaluation of 82 women with preterm premature rupture of the membranes from this institution has revealed a prolongation of latency and decrease in neonatal infectious morbidity with ampicillin therapy.[9] In this study the treated patients received intravenous ampicillin for 24 hours, followed by oral ampicillin until delivery, at which time parenteral therapy was reinitiated. Control patients received no antibiotics. An overall difference in survival curves was identified, but the nonblinded nature of this study may have introduced bias in patient management subsequent to randomization.

Morales et al.[10] reported on 165 women with preterm premature rupture of the membranes who were randomized into four different treatment schemes: no treatment ($n = 41$), steroids alone ($n = 43$), ampicillin alone ($n = 37$), or ampicillin and steroids ($n = 44$). There were no significant differences among the study groups with regard to mean latency period. The data were subsequently reanalyzed according to the use of antibiotics or steroids. There were no significant differences among these groups regarding gestational age at delivery or birth weight. Interestingly, the authors found differences of chorioamnionitis among the four

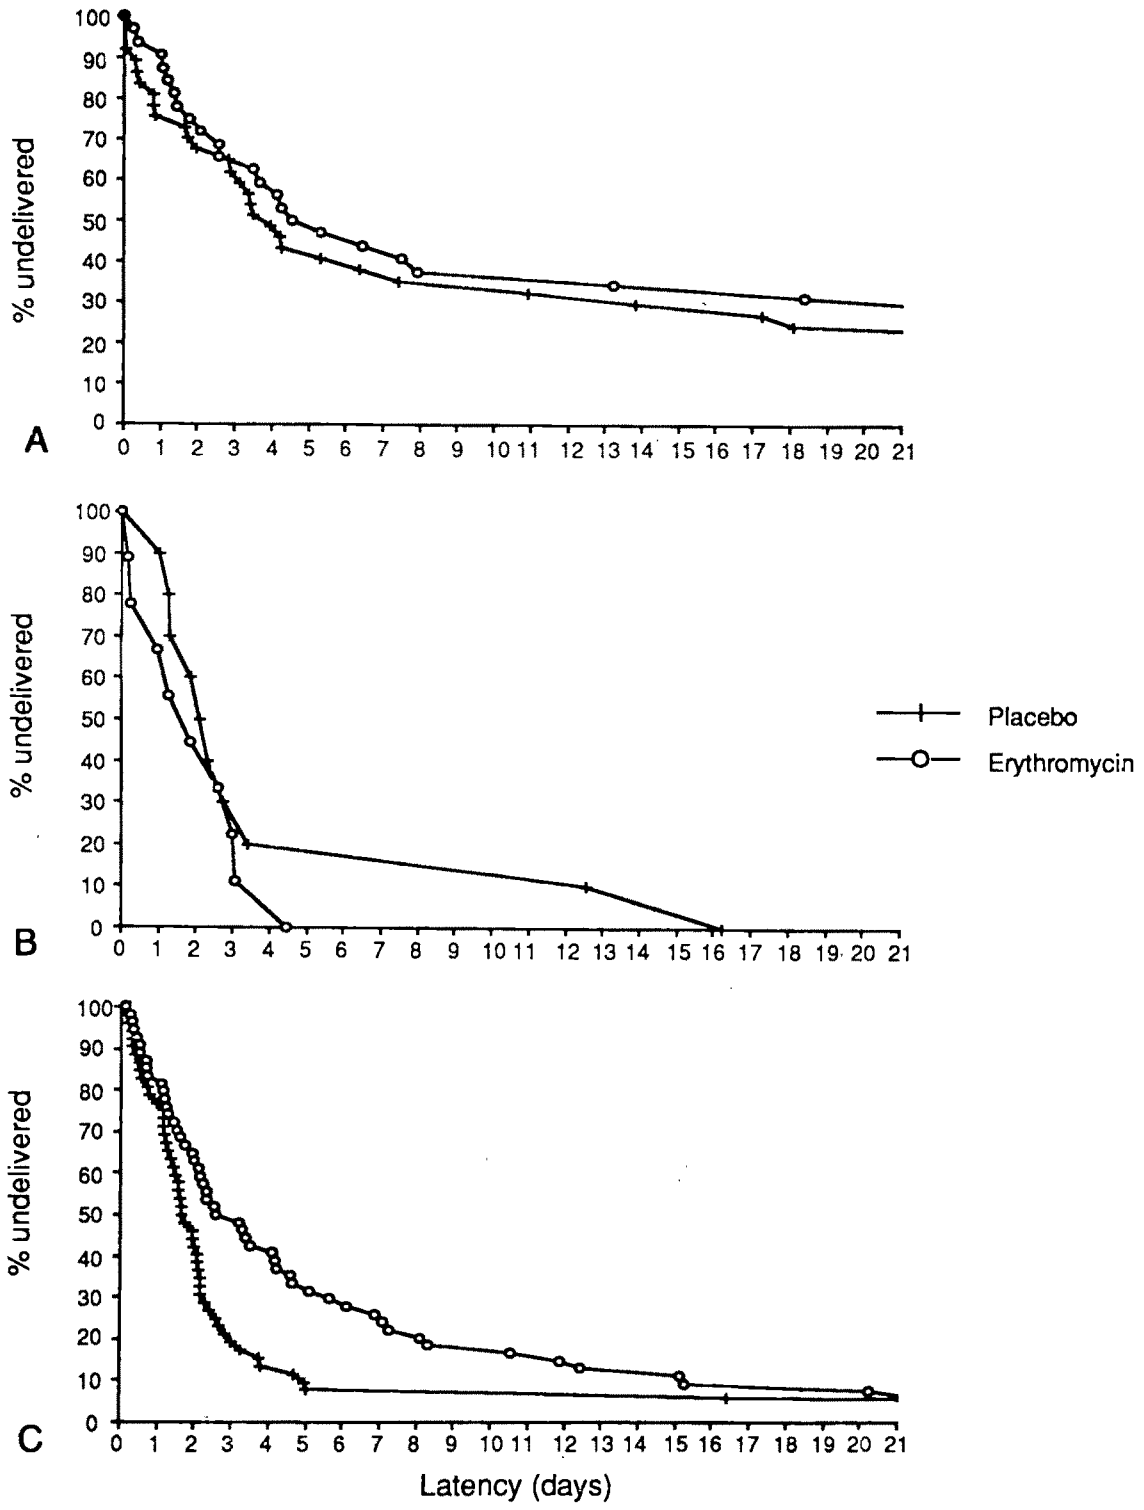

Fig. 3. Latency to delivery on basis of amniotic fluid culture results. **A,** Negative results of amniocentesis; **B,** positive results of amniocentesis; **C,** no amniocentesis (oligohydramnios).

study groups: lower incidences of neonatal sepsis in patients receiving ampicillin (with or without steroids) and a lower incidence of significant neonatal morbidities in the steroid-treated group (with or without ampicillin). This study was not blinded, and the sample size in each arm was small. Further, postrandomization exclusion was permitted. Finally, the results of this trial, randomized to multiple treatment arms, were analyzed

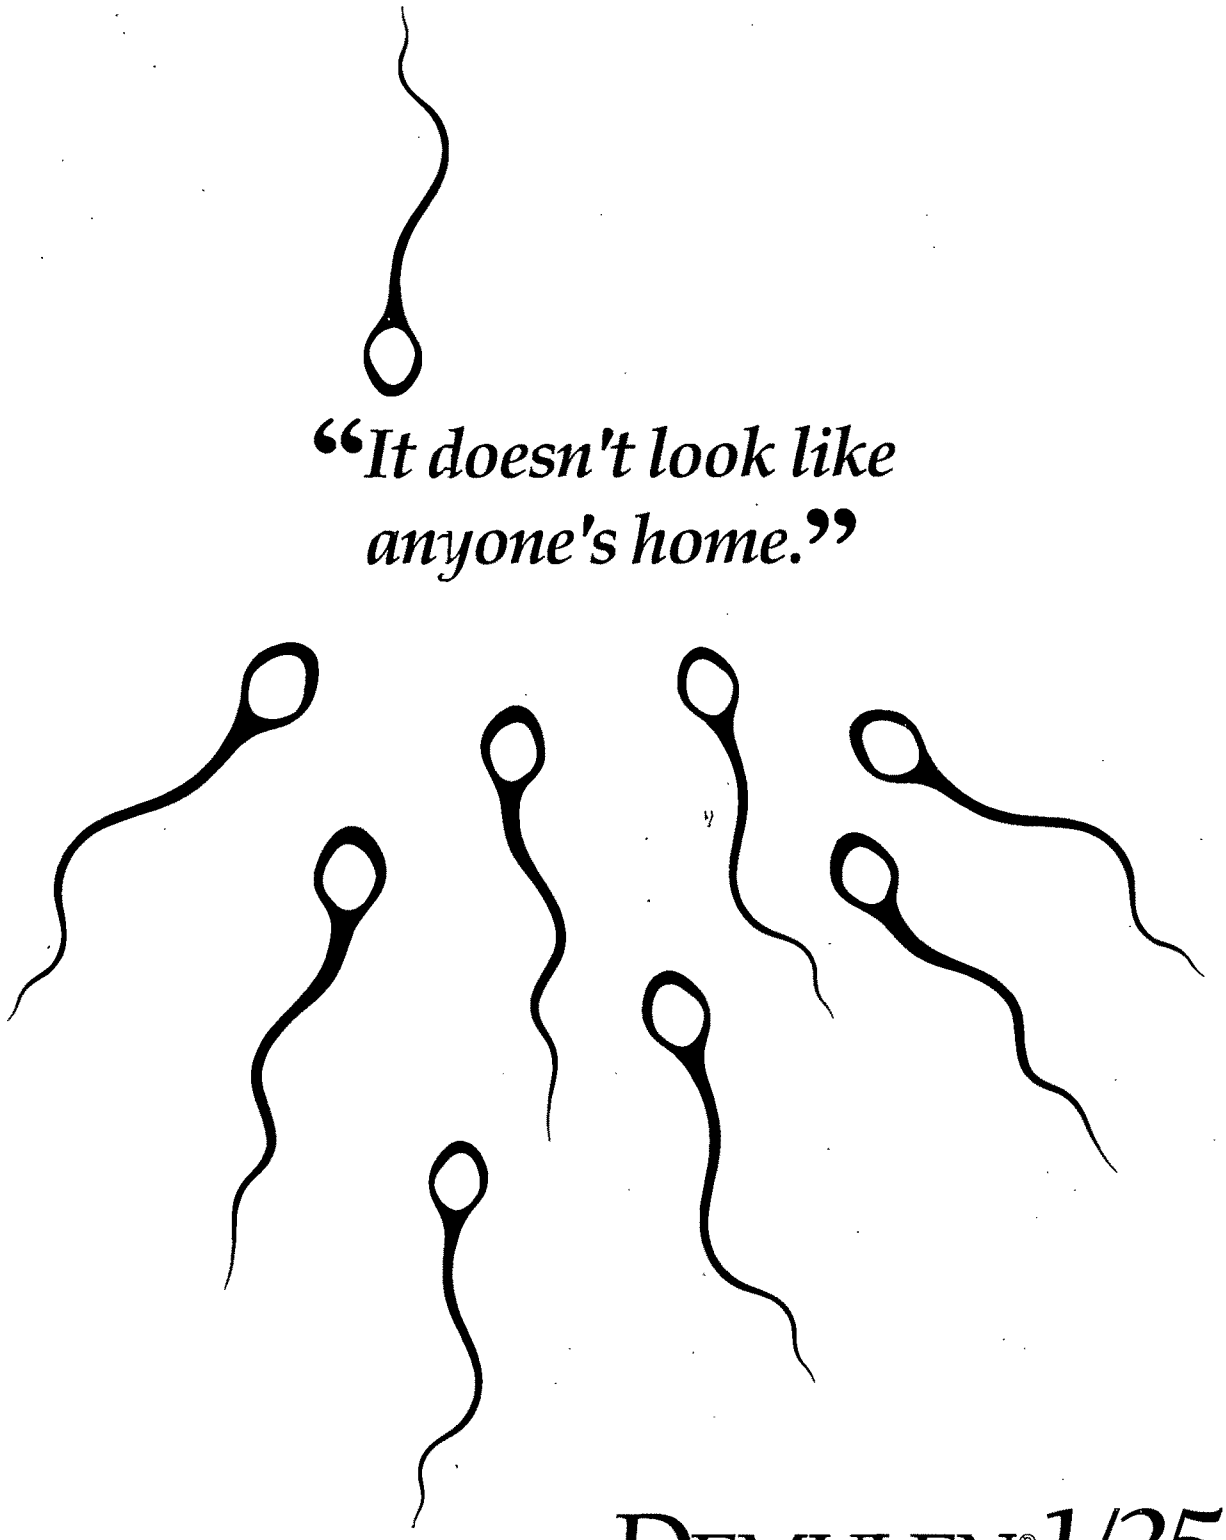
with univariate statistics. Thus it is difficult for us to come to any concrete conclusions on the basis of the presented data.

To our knowledge this is the first double-blind, randomized, placebo-controlled study with adequate sample size to assess the efficacy of oral erythromycin therapy in patients with preterm premature rupture of the membranes. We believed that a prolongation of latency by at least 1 week would be required to significantly reduce the incidence of neonatal sequelae. On the basis of the previous experience at this institution, we calculated that a sample size of 100 women would be required in each study arm to demonstrate a 20% increase in undelivered patients after 1 week of therapy (control group incidence of 29% undelivered, power = 0.80, $\alpha = 0.05$). As is outlined in Table II significant increases in the number of undelivered patients were obtained between 2 and 5 days after randomization. Although a trend toward pregnancy prolongation was seen after 7 days of therapy, this finding was not statistically significant ($p = 0.056$). Thus, although prolongation of latency is evident with erythromycin therapy, this effect is limited primarily to the first 5 days after initiation of treatment. Oral erythromycin therapy was not associated with a significant reduction in infant morbidity or mortality, although a trend toward a decrease in neonatal pneumonia was identified ($p = 0.06$). Given the similarities in the incidences of stillbirth, low 5-minute Apgar scores, and death from sepsis, a sample size of at least 1400 patients would be required to demonstrate a significant reduction ($\alpha = 0.05$, power = 0.80). A significantly larger sample size would be required to show a reduction in other morbidities.

In an attempt to identify a subgroup of women who might benefit more from antibiotic treatment, we assessed latency on the basis of the development of maternal infection at delivery. As depicted in Fig. 2, a statistically significant difference in latency was identified only in the population destined to have chorioamnionitis. It is interesting that the incidence of both clinical infection and suspected infection was not decreased with antibiotic therapy, but their onset was simply delayed.

Amniocentesis was performed when a 1 × 1 cm, cord-free pocket of amniotic fluid could be identified. With this policy, amniotic fluid was obtained in 45% of patients and there were no identified complications. Women with positive amniotic fluid cultures had short latencies and generally were delivered before the culture results became available. Two women in the placebo group with prolonged latencies (12 and 16 days) had enterococci grown from the amniotic fluid. Thus oral erythromycin was not effective in delaying delivery in the group of women with positive amniotic fluid cultures. The group with adequate fluid and negative cultures appeared to be at low risk for infection and therefore did not benefit from antibiotic therapy. Surprisingly, a significant delay in delivery was seen in the population with initial oligohydramnios precluding amniocentesis. It has been previously postulated that oligohydramnios is associated with an increased risk of subsequent clinical infection.[13, 14] The findings of this study indicate that this subgroup of patients might benefit from the use of prophylactic antibiotic therapy.

Morales et al.[10] found that the use of ampicillin therapy in patients with premature rupture of the membranes was effective in prolonging latency period only in those women colonized by group B streptococci. Evaluation of our patients revealed similar trends toward prolongation of latency period regardless of colonization with either group B streptococci or *C. trachomatis*. In addition, no prolongation was seen in women with positive cervical *N. gonorrhoeae* cultures. However, because of the small sample size within these subpopulations, statistical inferences cannot be made.



In this study we have observed a wide variety of organisms in the amniotic fluid collected at amniocentesis. Ascending infection with deciduitis and subsequent chorioamnionitis has been postulated with preterm premature rupture of the membranes[15, 16]; therefore it would be reasonable to target antibiotic therapy at these organisms. Erythromycin enjoys rapid oral absorption and has good pelvic soft tissue penetration.[17, 18] In addition, it is effective against a variety of gram-positive and gram-negative organisms, *C. trachomatis*, and *Ureaplasma urealyticum*.[19] On the other hand, ampicillin and clindamycin are broad-spectrum agents with overlapping and antimicrobial activity complementary to erythromycin.[20] Thus combinations of these three agents, in oral or parenteral form, or single agents with broader-spectrum coverage might be more effective in treating the organisms identified in the amniotic fluid of patients studied.

In summary, the use of prophylactic oral erythromycin therapy in patients with preterm premature rupture of the membranes resulted in significant prolongation of latency period. However, this therapy was not associated with any reduction in either maternal or neonatal morbidity.

DEMULEN® 1/35

(ethynodiol diacetate 1 mg, ethinyl estradiol 35 mcg)

Where protection begins

The physician should become familiar with the prescribing information (labeling) for this product, which discusses reported risks, such as thromboembolic disorders (including strokes and heart attacks), risk of estrogen dose, and hepatic lesions, as well as the need to monitor patients for early symptoms of any diseases or medical conditions, so use can be discontinued when appropriate.

Please see adjoining page for a brief summary of prescribing information.

The OC innovator **SEARLE**

DEMULEN® 1/35

(ethynodiol diacetate 1 mg, ethinyl estradiol 35 mcg)

Where protection begins

BRIEF SUMMARY

Demulen® 1/35: Each white tablet contains ethynodiol diacetate 1 mg and ethinyl estradiol 35 mcg. Each blue tablet in Demulen 1/35-28 is a placebo containing inert ingredients. **Demulen® 1/50:** Each white tablet contains ethynodiol diacetate 1 mg and ethinyl estradiol 50 mcg. Each pink tablet in Demulen 1/50-28 is a placebo containing inert ingredients.

Indication and usage: For prevention of pregnancy. Pregnancy rate for products with ≥35 mcg ethinyl estradiol or ≥50 mcg mestranol is ≤1/100 woman-years. With ≤35 mcg ethinyl estradiol, rate is slightly higher; with progestogen-only oral contraceptives (OCs), rate is about 3. Precise comparisons cannot be made. Rates for other methods have been published.

Dose-related Thromboembolic Risk: Studies showed positive association between OC estrogen dose and thromboembolic risk. It is in keeping with good therapeutics to minimize estrogen exposure. Prescribe product containing least amount of estrogen compatible with acceptable pregnancy rate and patient acceptance. Start new users on ≤50 mcg estrogen.

Contraindications: Thrombophlebitis; thromboembolic disorders, past history of deep vein thrombophlebitis or thromboembolic disorders; cerebrovascular disease, myocardial infarction or coronary artery disease, or past history of these; known or suspected breast carcinoma, estrogen-dependent neoplasia, or pregnancy; undiagnosed abnormal genital bleeding; past or present, benign or malignant liver tumors developing during use of estrogenic products.

Warnings:

Cigarette-smoking increases risk of serious cardiovascular side effects from OC use. Risk increases with age and heavy smoking (15 or more cigarettes/day) and is quite marked in women over 35. OC users should be strongly advised not to smoke. OCs are associated with increased risk of several serious conditions including venous and arterial thromboembolism, thrombotic and hemorrhagic stroke, myocardial infarction, visual disorders, hepatic tumors, gallbladder disease, hypertension, fetal abnormalities. Practitioners should be familiar with the available information relating to these and other risks.

1. *Thromboembolic disorders and other vascular problems:* Increased risk of thromboembolic and thrombotic disease associated with OCs is well established. A British study showed increased risk for fatal venous thromboembolism (TE). British and U.S. studies showed increased risk for nonfatal disease. U.S. studies showed increased risk for stroke. OC users were 2-11 times more likely to manifest these diseases without evident cause. In a study of idiopathic deep vein thrombosis and pulmonary embolism (PE), projected hospitalization rates for ages 15-40 were 47/year/100,000 users and 5 for nonusers. Overall excess mortality from PE or stroke was 1.3-3.4 deaths/year/100,000 users and increased with age. *Cerebrovascular Disorders:* In a study of stroke with and without predispositions, risk of hemorrhagic stroke was 2 times greater and thrombotic stroke 4.0-9.5 times greater in users. Mortality trends in 21 countries indicate that changes in cardiovascular mortality were associated with changes in OC prevalence. The Royal College of GPs (RCGP) reported on its prospective study: "A statistically significant higher rate of reporting of cerebrovascular accidents in Takers is evident, but the numbers are too small to justify an estimation of the degree of risk." A 1981 analysis showed a 4-fold increased mortality in users from circulatory diseases, mainly myocardial infarction (MI) and hemorrhagic stroke. Excess mortality was associated with age and smoking. A 1983 analysis showed elevated cerebrovascular disease, increasing with use to 8 yrs, including cerebral thrombosis or embolism and TIA. Peripheral arterial disease and MI were increased. Women over 30 had more arterial disease, being greatest in smokers. Arterial case-fatality was 2-3 times greater for users who smoked. Family Planning Assoc. (FPA) found significant association between OC use and stroke; increased risk for venous thrombosis and PE was 4-fold and statistically significant. Mortality from nonrheumatic heart disease was greater in ever-users. In the Walnut Creek Study, subarachnoid hemorrhage risk was associated with smoking, age, and OC use. *Myocardial Infarction:* Increased risk of MI associated with OCs was reported in Britain, as previously suspected. The morbidity study found the greater the number of risk factors for coronary artery disease (smoking, hypertension, hypercholesterolemia, obesity, diabetes, history of preeclamptic toxemia) the higher the risk, regardless of OC use. OCs were an additional risk factor. Excess rate of fatal MI was 3.5/year/100,000 users aged 30-39 and 20 for ages 40-44. (These are based on British statistics with acute MI death rates 2-3 times less than the U.S. Similar estimates for the U.S. are 25.7 for users aged 30-39 with predispositions vs 1.5 without; for ages 40-44, 86.2 vs 5.1.) Excess hospitalization rate for nonfatal MI in Britain was 3.5/year/100,000 users aged 30-39 and 47 for ages 40-44. Smoking is a major predisposing condition to MI. In terms of relative risk, nonsmoking OC users are twice as likely to have fatal MI as nonsmoking nonusers. Smoking users have a 5-fold greater risk than nonsmoking users, but a 10-12-fold greater risk than nonsmoking nonusers. Amount of smoking is an important factor. In determining importance of these risks, give serious consideration to rates in table below. Importance of other predispositions cited above in determining relative and absolute risks has not been quantified; it is likely the same synergism exists, but perhaps to a lesser extent. U.S. studies similarly relate MI, OCs, smoking, and age.

Estimated Mortality Rate from Myocardial Infarction per 100,000 Women/Year

	Aged 30-39:	*Users*	*Nonusers*	*Aged 40-44:*	*Users*	*Nonusers*
All smokers		10.2	2.6		62.0	15.9
≥15 cigarettes daily		13.0	5.1		78.7	31.3
<15 cigarettes daily		4.7	0.9		28.6	5.7
Nonsmokers		1.8	1.2		10.7	7.4
Smokers and nonsmokers		5.4	1.9		32.8	11.7

Risk of Dose: Reports of TE after use of OCs with ≥50 mcg estrogen received by drug safety committees in Britain, Sweden, and Denmark were compared with distribution expected from market research sales estimates. A positive correlation was found between estrogen dose and reporting of TE, including coronary thrombosis, in excess of that predicted by sales. OCs with ≥100 mcg estrogen were associated with higher TE risk than those with 50-80 mcg. Estrogen quantity may not be the sole factor; influence of progestogens was not considered, which may be responsible for certain discrepancies in the data. No significant differences were noted between OCs containing same estrogen dose nor between ethinyl estradiol and mestranol. In Britain certain TE conditions were associated with progestogen or estrogen dose. In Sweden reports of TE decreased when higher estrogen doses were no longer prescribed. Studies on TE risk with progestogen-only OCs have not been done. Cases have been reported for these; they are not presumed free of risk. In a U.S. case-controlled study, relative risk of OC use 1 month before hospitalization for various types of TE was calculated. If relative estrogenic potency and possible influence of different progestogens are ignored, OCs may be divided into those with <100 mcg and those with ≥100 mcg estrogen. For all cases combined, larger doses were associated with only slightly higher risk; for idiopathic cases risk was doubled with larger doses, but confidence limits overlapped and differences were not significant. Apparently there was less increased risk for cases with predispositions. In FPA study no nonhemorrhagic strokes occurred with <30 mcg estrogen, vs 13 with higher doses. Latter group also had more venous TE. TE risk in users and nonusers increases with age. OCs have been considered an independent risk factor. Decreased HDL, which relates to increased myocardial ischemia, occurs with high progestational activity. Consider amount of both steroids in choosing OC. *Persistence of Risk* after OC discontinuation was reported for circulatory disease, nonrheumatic heart disease, and cerebrovascular disease, including subarachnoid hemorrhage, cerebral thrombosis, and TIA. *Excess Mortality from Circulatory Diseases:* A U.K. prospective study estimated annual mortality from circulatory diseases for OC users and nonusers by age, smoking, and duration of use. Excess mortality was 23/100,000 users (2 and 10 for ages 25-34, 15 and 48 for ages 35-44, 41 and 179 for ages >44, for nonsmokers and smokers, respectively). Risk was significant only for smokers over 34. Most deaths were due to subarachnoid hemorrhage or ischemic heart disease. Risk for ever-users rose with parity. One study estimated risk of death with various contraceptive methods, each estimate including risk of method (eg, TE for OCs) plus risk due to pregnancy or abortion in cases of method failure. This latter risk varies with effectiveness. It concluded mortality with all methods is low and below that of childbirth, except for OC users over 40 who smoke. Heavy smokers have double the risk of smokers, light smokers about half. Mortality with OC use in nonsmokers over 40 is higher than with any other method in that age group. Lowest mortality is with condom or diaphragm backed up by early abortion. Risk of TE and thrombotic disease with OCs increases with age after 30 and, for MI, is further increased by hypertension, hypercholesterolemia, obesity, diabetes, history of preeclamptic toxemia, and especially cigarette smoking. Based on current data, the chart gives gross estimates of risk of death from circulatory disorders associated with OCs:

Risk is: A—very high; B—high; C—moderate; D—low.	Age:	<30	30-39	≥40
Heavy smokers (≥15/day)		C	B	A
Light smokers (<15/day)		D	C	B
Nonsmokers, no predispositions		D	C,D	C
Nonsmokers, with predispositions		C	C,B	B,A

Be alert to earliest manifestations of TE disorders (eg, thrombophlebitis, PE, cerebrovascular insufficiency, coronary artery disease, MI, retinal thrombosis, mesenteric thrombosis). Should any be suspected, discontinue OCs immediately. A 4-7-fold increased risk of postsurgery TE was reported in users; if feasible discontinue OCs at least 4 weeks before surgery or in prolonged immobilization. Before resuming OCs, weigh risks of postsurgery TE complications against contraceptive needs. RCGP reported higher incidence of superficial and deep vein thrombosis in users, the former correlated with progestogen dose. Varicose veins have little effect on development of deep vein thrombosis. 2. *Ocular lesions:* Neuro-ocular lesions such as optic neuritis or retinal thrombosis have been associated with OCs. Discontinue if there is unexplained, gradual or sudden, partial or complete loss of vision; proptosis or diplopia; papilledema; or evidence of retinal vascular lesions. Institute diagnostic and therapeutic measures. 3. *Carcinoma:* Long-term estrogen in certain animals increases carcinomas and/or nonmalignant neoplasms, such as those of breast, uterus, cervix, vagina, ovary, liver, pituitary. Some synthetic progestogens, none currently in OCs, increase incidence of benign and malignant mammary nodules in dogs. Estrogens increase risk of human endometrial carcinoma. In case-controlled studies, increased risk (2.2-13.9 times) associated endometrial carcinoma with prolonged estrogen for menopausal symptoms. Risk was independent of other known risk factors and depended on duration of use and dose. This is supported by increased endometrial cancer incidence since 1969 in areas with cancer-reporting systems, which may be related to expanding estrogen use. There is no evidence that natural estrogens are more or less hazardous than synthetics. Of the first 30 cases of endometrial carcinoma in OC users under 40, those without predispositions occurred nearly always with no-longer-marketed sequential OCs. No statistical association is reported suggesting increased endometrial cancer with combination or progestogen-only OCs. Studies show no increased breast cancer with OCs or estrogens. However, greater risk was noted in OC users with benign breast disease or long-term (2-4 years) use. One study found greater risk of breast cancer with >4 years OC use prior to first full-term pregnancy. Risk of breast cancer with menopausal estrogens rose, and further increased with duration of follow-up. OCs or estrogen were related to breast cancer in connection with other risk factors and in various subgroups. Decrease in benign breast tumors in OC users is well known. Some studies suggested increased risk of cervical dysplasia, CIN, erosion, and carcinoma in long-term users. Cervical microglandular hyperplasia has been reported. In summary, there is no consistent evidence from human studies of increased cancer risk with OCs. Close surveillance is, however, essential. In undiagnosed persistent or recurrent abnormal vaginal bleeding, consider nonfunctional causes and take diagnostic measures to rule out malignancy. Carefully monitor users with strong family history of breast cancer or with breast nodules, fibrocystic disease, recurrent cystic mastitis, abnormal mammograms, or cervical dysplasia. 4. *Hepatic adenomas, etc.* have been associated with OCs. In 1 study OC formulations with high "hormonal potency" were associated with higher risk, as was age over 30. Though benign, these lesions may rupture and cause fatal hemoperitoneum in short- or long-term users. Two studies related risk to duration of use, being much greater after ≥4 years. Long-term OC users have an estimated adenoma incidence of 3-4/year/100,000. Consider such lesions in users with abdominal pain, tenderness, mass, or shock. About 25% present with abdominal masses, up to half with acute hemoperitoneum. Radiologic and lab studies may not be helpful; liver scans may show local defect. Hepatic arteriography or CAT may be useful. Hepatocellular carcinoma risk is increased 7-20 times in users for 8 or more years. Bile duct cancer may occur with OC use. 5. *Use in or immediately preceding pregnancy, birth defects, malignancy in offspring:* Estrogens or progestogens during early pregnancy may seriously damage offspring. Females exposed in utero to DES and other nonsteroidal estrogens may have increased risk of vaginal or cervical cancer. Though OCs may not enhance this risk, monitor such patients carefully. From 30-90% of DES-exposed women develop benign vaginal or cervical adenosis, which could be premalignant. DES-exposed daughters have more unfavorable pregnancy outcomes. Males so exposed may develop urogenital and sperm defects. Other estrogens may mimic DES. Reports relate fetal exposure to female sex hormones and congenital anomalies, eg, VACTERL for vertebral, anal, cardiac, tracheoesophageal, renal, and limb defects. There appears preferential expression by males. There was a 4.7-fold increased risk of limb-reduction defects in infants exposed in utero to sex hormones (OCs, hormonal withdrawal pregnancy tests, or treatment for threatened abortion). Some exposures were very short, being only a few days. Cardiovascular defects in children exposed to female hormones, including OCs, during early pregnancy occurred in 18.2/1,000 births, compared to 7.8 for those unexposed (P<.05). Female hormone exposure in utero was associated with testicular and ovarian cancer. More twinning was reported in conceptions shortly after OC discontinuance. Female sex hormones were used for threatened or habitual abortion, but there is considerable evidence estrogens are ineffective and no evidence progestogens are effective. Triploidy and possibly other polyploidy may be increased in abortuses from women becoming pregnant soon post-OC. These almost always abort spontaneously. It is unknown if spontaneous abortion is increased soon after stopping OCs. Increased chromosome aberrations have been reported. Safety of OCs in pregnancy has not been demonstrated. Rule out pregnancy in using OCs and always consider it if withdrawal bleeding does not occur. If 2 consecutive periods are missed rule out pregnancy before continuing. If user deviates from regimen, consider pregnancy at first missed period and withhold OCs. If pregnancy is confirmed, stop OC and apprise patient of potential fetal risks and discuss continuation of pregnancy. Users discontinuing for pregnancy should use alternative contraceptive for 3 months before attempting to conceive, though this is not based on precise information. Do not use progestogen-only or progestogen-estrogen drugs as pregnancy tests. 6. *Gallbladder disease* risk, surgically confirmed, appeared after 2 years' use and doubled after 4-5 years in 1 study; it appeared in 6-12 months' use in another. Bile duct cancer has been reported. 7. *Carbohydrate and lipid metabolism:* Decreased glucose tolerance occurs in a significant number of users; carefully observe diabetic and prediabetic patients. Triglycerides, total phospholipids, and lipoproteins may increase. 8. *Elevated blood pressure* (BP) occurs in some users in a few months, and degree may relate to progestogen dose. Hypertension prevalence in users is not higher in the first year, but increases with longer exposure; in the 5th year it is 2½–3 times the first year. Age is strongly correlated with hypertension in users. Those with history of elevated BP (hypertension), preexisting renal disease, history of toxemia or elevated BP in pregnancy; familial tendency to hypertension or its consequences, or history of excessive weight gain or fluid retention during menstrual cycles may be more likely to develop elevated BP on OCs and should be monitored closely. Even though elevated BP may be in "normal" range, do not ignore implications. Follow closely, particularly those with other risk factors for cardiovascular disease or stroke. High BP may or may not persist after stopping OCs. 9. *Headache:* Onset or exacerbation of migraine or development of headache of a new pattern that is recurrent, persistent, or severe requires stopping OCs and evaluating cause. 10. *Bleeding irregularities:* Breakthrough bleeding (BTB), spotting, and amenorrhea are frequent reasons for discontinuing. In BTB, as in all cases of irregular bleeding, consider nonfunctional causes. In undiagnosed persistent or recurrent bleeding, rule out pregnancy or malignancy. If pathology is excluded, time or change to another product may suffice. Change to a higher-estrogen OC only when necessary as this may increase thromboembolic risk. Those with history of oligomenorrhea or secondary amenorrhea or without established regular cycles may be anovulatory or amenorrheic after discontinuing. Those with such problems should be so informed and other methods encouraged. Post-use anovulation, possibly prolonged, may occur in women without previous irregularities. Higher incidence of galactorrhea and of pituitary tumors has been associated with postpill amenorrhea. One study reported 16-fold increased prevalence of pituitary prolactin-secreting tumors in patients with postpill amenorrhea when galactorrhea was present. 11. *Ectopics:* In failures with combination OCs, the ratio of ectopic to intrauterine pregnancies is no higher than in nonusers. 12. *Breast feeding:* OCs may decrease quantity and quality of milk. A small fraction of OC steroids appears in milk. Effects if any on child are unknown. If feasible defer OCs until after weaning. 13. *Infertility* may occur after discontinuing OCs. While impairment diminishes with time, there is still an appreciable difference in nulliparas aged 25-29 after 30 months; difference is negligible after 48 months. In nullips aged 30-34 impairment persists to 72 months and is more severe for 2-year users. In paras aged 25-34, difference is negligible after 30 months. **Precautions:** Conduct complete history and physical prior to OC use and annually thereafter. Include breasts, abdomen, and pelvis, with BP, Pap, and lab tests. Preexisting uterine leiomyomata may enlarge. Mental depression may occur; with positive history, observe carefully and discontinue if serious recurrence. Fluid retention may occur; prescribe cautiously and monitor carefully in convulsive disorders, migraine, asthma, or cardiac, hepatic, or renal dysfunction. History of jaundice in pregnancy increases risk of recurrence on OCs; observe carefully and discontinue if it occurs. Cholestatic jaundice occurred after OC and troleandomycin use. OC/cyclosporine combination may be hepatotoxic. Steroids may be poorly metabolized in liver dysfunction and should be given cautiously. Tryptophan metabolism may be disturbed and result in pyridoxine deficiency; megaloblastic anemia has been reported. Serum folate may be depressed and may be exacerbated in post-OC pregnancy. Advise pathologist of OC use when submitting specimens. Endocrine and liver function tests may be altered; repeat abnormal tests after stopping for 2 months. These have been observed: increased BSP retention and other abnormalities in liver function tests; increased prothrombin and coagulation factors VII, VIII, IX, X; decreased antithrombin III, increased platelet aggregability; increased thyroid-binding globulin leading to increased circulating total thyroid hormone (PBI, T_4); decreased T_3 uptake, unaltered free T_4, decreased pregnanediol excretion; reduced metyrapone response; increased blood transcortin, corticosteroid, triglyceride, phospholipid, reduced serum folate; impaired glucose tolerance; altered plasma trace minerals. Influence of prolonged OC use on pituitary, ovarian, adrenal, hepatic, or uterine function, or on immune response not established. OCs may mask onset of climacteric. Cervical chlamydial and gonorrheal prevalence is increased; do not assume OC protects against chlamydial PID. HIV seropositivity was associated with OC use. *Information for patients.* See patient labeling. *Drug interactions.* OC effectiveness may be decreased and more BTB occur with rifampin, isoniazid, ampicillin, neomycin, penicillin V, tetracycline, chloramphenicol, sulfonamides, nitrofurantoin, griseofulvin, barbiturates, phenytoin, carbamazepine, primidone, phenylbutazone, analgesics, tranquilizers, antimigraines. OCs may alter effectiveness of oral anticoagulants, anticonvulsants, tranquilizers, tricyclic antidepressants, antihypertensives, theophylline, caffeine, vitamins, hypoglycemics, clofibrate, glucocorticoids, acetaminophen. **Adverse reactions:** Increased risk of the following serious adverse reactions has been associated with OCs: thrombophlebitis and thrombosis; pulmonary embolism; arterial thromboembolism; Raynaud's disease, myocardial infarction; coronary thrombosis; cerebral thrombosis; cerebral hemorrhage; hypertension; gallbladder disease; Budd-Chiari syndrome; benign adenomas and other hepatic lesions, with or without intra-abdominal bleeding, liver cancer, congenital abnormalities. There is evidence of association between the following and OCs, though confirmatory studies have not been done: mesenteric thrombosis; neuro-ocular lesions, eg, retinal thrombosis and optic neuritis. The following are believed drug related: nausea, vomiting, gastrointestinal symptoms, BTB, spotting, change in menstrual flow, dysmenorrhea, amenorrhea during and after use, infertility post-OC, edema, chloasma or melasma, which may persist post-OC, breast changes (tenderness, enlargement, secretion), weight changes, change in cervical erosion and secretion, endocervical hyperplasia, lactation decrease, cholestatic jaundice, migraine, enlarged uterine leiomyomata, allergic rash, mental depression, reduced carbohydrate tolerance, vaginal candidiasis, change in corneal curvature (steepening), intolerance to contact lenses. Association not confirmed or refuted for: premenstrual-like syndrome, cataracts, libido changes, chorea, appetite changes, cystitis-like syndrome, headache, paresthesia, nervousness, dizziness, auditory disturbances, rhinitis, fatigue, backache, hirsutism, scalp hair loss, erythema multiforme or nodosum, hemorrhagic eruption, herpes gestationis, hidradenitis suppurativa, hemolytic uremia, malignant hypertension, impaired renal function, acute renal failure, sometimes irreversible, itching, vaginitis, porphyria, PVCs, abnormal EKG, pulmonary hypertension, TTP, anemia, pancreatitis, hepatitis, colitis. Crohn's disease, gingivitis, dry socket, lupus erythematosus, rheumatoid arthritis, pituitary tumors (eg, adenoma) with amenorrhea and/or galactorrhea after use, malignant melanoma, endometrial, cervical, breast, and bile duct carcinoma. **Acute overdosage:** Serious ill effects have not been reported after large acute doses of OCs in young children. Nausea and withdrawal bleeding might occur. **Important note: Complete prescribing information should be consulted prior to use and is available on request.**

Oral folic acid supplementation for cervical dysplasia: A clinical intervention trial

C.E. Butterworth, Jr., MD,[a] K.D. Hatch, MD,[b] Seng-Jaw Soong, PhD,[c] Philip Cole, MD,[d] Tsunenobu Tamura, MD,[a] Howerde E. Sauberlich, PhD,[a] Matthew Borst, MD,[b] Maurizio Macaluso, MD,[d] and Vicki Baker, MD[b]

Birmingham, Alabama

OBJECTIVE: We attempted to evaluate the effect of oral folic acid supplementation on the course of cervical dysplasia.

STUDY DESIGN: A total of 235 subjects with grade 1 or 2 cervical intraepithelial neoplasia were randomly assigned to receive either 10 mg of folic acid or a placebo daily for 6 months. Clinical status, human papillomavirus type 16 infection, and blood folate levels were monitored at 2-month intervals. Outcome data were subjected to χ^2 analysis.

RESULTS: The prevalence of human papillomavirus type 16 infection initially was 16% among subjects in the upper tertile of red blood cell folate versus 37% in the lower tertile (trend $p = 0.035$). After 6 months no significant differences were observed between supplemented and unsupplemented subjects regarding dysplasia status, biopsy results, or prevalence of human papillomavirus type 16 infection.

CONCLUSION: Folate deficiency may be involved as a cocarcinogen during the initiation of cervical dysplasia, but folic acid supplements do not alter the course of established disease. (AM J OBSTET GYNECOL 1992;166:803-9.)

Key words: Cancer, cervical dysplasia, nutrition, folate, papillomavirus

There is evidence that folate deficiency may be involved in the etiology of cancer of the cervix,[1, 2] esophagus,[3] colon,[4] bronchi,[5] and hematopoietic system of humans,[6] as well as in certain experimental models of carcinogenesis.[7] Considerable interest has developed in cervical dysplasia (cervical intraepithelial neoplasia and squamous intraepithelial lesions), not only because of its high incidence but also because of a possible relationship to oral contraceptive agents,[8] which are reported to lower circulating folate levels[9] and to modify cervical cytologic characteristics.[1, 10] Recent evidence[10a] has shown that folate nutritional status interacts strongly with several established risk factors for cervical intraepithelial neoplasia, such as cigarette smoking, infection with human papillomavirus (HPV), parity, and oral contraceptive use. Normal levels of folate appear to protect against cervical intraepithelial neoplasia and to minimize the risks ordinarily associated with these factors. Cigarette smoking, pregnancy, and oral contraceptive use may be associated with depressed circulating levels of folate.

The role of papillomavirus infection as an etiologic factor in cervical dysplasia remains perplexing. Although HPV genomes can be demonstrated in a high proportion of cervical cancers,[11] they are also demonstrable in cervicovaginal cells from normal women[12] and in normal tissue adjacent to neoplastic lesions.[13] For these reasons it is necessary to consider whether the oncogenic potential of HPV genomes is expressed or remains latent.

In 1982 Butterworth et al.[1] reported that a 3-month period of daily oral folic acid supplementation in 22 subjects was associated with improvement in the cytologic manifestations of dysplasia and with less severe biopsy findings when compared with those of 25 placebo-treated control subjects. The study was undertaken because of morphologic similarities between the cytologic features of megaloblastosis seen with folate deficiency and the changes associated with dysplasia.[1] Megaloblastic features are "deceptively similar" to those observed in early cervical cancer.[14] The report by Butterworth et al.[1] suggested that localized folate deficiency, which is sometimes misdiagnosed as cervical dysplasia, could be a component of the dysplastic process. Subsequently, a larger and more comprehensive study with two major parts was organized by Butterworth et al. (unpublished data). In the first phase of the project a case-control study that was based on 464 subjects derived from screening of 726 candidates was

reported.[10a] Women who qualified were invited to participate in the second phase, a randomized, placebo-controlled, double-blind clinical intervention trial that required three additional visits at 2-month intervals. We present the findings in 235 subjects who were randomized to receive either the folic acid supplement or placebo.

Material and methods

This project was reviewed, approved, and monitored annually by the Institutional Review Board of the University of Alabama at Birmingham. Informed consent was given by all participants. All subjects were women attending a county health department clinic, usually for family planning, although other reasons included postpartum examination and routine health evaluation. The original examination and Papanicolaou smear collection were performed by a nurse-practitioner. Subjects with abnormal findings were referred to the central colposcopy clinic operated by the Department of Obstetrics and Gynecology of the University of Alabama at Birmingham in conjunction with the county health department. A physician gave each subject a gynecologic examination that included colposcopy, a routine Papanicolaou test, a herpes culture, a wet smear for vaginal pathogens such as trichomonas, chlamydia, and candida, when indicated, and a cervicovaginal scraping to test for HPV-16. Lesions were diagramed and photographed. The squamocolumnar transition zone was identified. Punch biopsy was deferred. A confidential questionnaire to obtain the gynecologic history, educational background, demographic data, socioeconomic status, and personal habits of each participant was administered by a registered nurse.

A case was defined as a woman with a combination of two abnormalities: at least one abnormal Papanicolaou smear showing mild or moderate cervical dysplasia (grade 1 or 2 cervical intraepithelial neoplasia) and a lesion with features of dysplasia visible by colposcopy. All Papanicolaou smears and all biopsy specimens were evaluated by the same cytopathologist. The degree of severity of disease at the time of entry into the study was determined by the most advanced reading of any available smear. The cervical intraepithelial neoplasia classification was based on criteria described by Ferenczy and Winkler.[15] With respect to the Bethesda system grade 1 cervical intraepithelial neoplasia corresponds to "low-grade squamous intraepithelial lesion with mild dysplasia" and grade 2 and 3 cervical intraepithelial neoplasia corresponds to "high-grade squamous intraepithelial lesion and moderate or severe dysplasia." An additional category consisted of women with lesions visible with colposcopy but with cytologic features, such as nuclear enlargement and irregularity, that are not diagnostic of dysplasia. Patients with these lesions were classified as having "atypia less than dysplasia"; they were not included in the current series of cases and have been described separately.[16]

Accrual of patients and data began in November 1985 and extended through March 1990. After the interview, evaluation, and collection of baseline data, women who qualified as cases were invited to enter the vitamin supplement trial and to return for three additional follow-up examinations at 2-month intervals. The risks and benefits of study participation were carefully explained, and the option of conventional management at any time (including local surgical procedures such as cryosurgery or laser beam surgery) was provided. Colposcopic and cytologic examination was performed at each visit. In addition, a punch biopsy was performed under direct vision at the final visit. Subjects received a 2-month supply of capsules that appeared identical but contained either 10 mg of folic acid (pteroylglutamic acid, United States Pharmacopeia) or 10 mg of ascorbic acid (United States Pharmacopeia) as the placebo. Ascorbic acid was selected as a placebo because it would not be likely to have a therapeutic effect in an apparently healthy population at this level of intake. Allocation to a treatment group was made on the basis of a computer-generated list of random numbers maintained by the pharmacy staff, so that all persons involved in patient management were unaware of treatment status. Prescription refills were in accord with the prior assignment.

Laboratory procedures. Blood specimens (taken with the patient in a nonfasting state) were collected at each visit, protected from light, and processed within 3 hours. Processed samples were stored in aliquots at −70° C for analysis at a later time, usually within a few days. Standard quality-control procedures were used during the study to ensure reproducibility. All procedures for biochemical assessment of nutritional status followed standard methods as described by Butterworth et al.[10a] Folate assays in plasma and red blood cells used *Lactobacillus casei* as the test organism.

HPV detection was performed with the Southern blot deoxyribonucleic acid (DNA) hybridization method[16, 17] on cells obtained by cervicovaginal scraping at the time of colposcopy at the first visit and at the final visit. HPV-16 DNA cloned in pBR322 was generously provided by Dr. Harald zur Hausen. Each blot contained an extract of the cervical carcinoma cell line CaSki (American Type Culture Collection) as its HPV-16 positive marker, an extract of normal placenta as the negative marker, and appropriate markers to indicate molecular size.

All results were computerized, stored, and processed in a single centralized location. Information regarding demographic characteristics, clinical and nutritional assessments, treatment, and follow-up status was recorded on specially designed case report forms to facilitate computerization and processing. Quality-con-

trol procedures and a feedback system were instituted to ensure the accuracy and completeness of the data collected. The χ^2 test was used to test the homogeneity of the treatment groups with respect to baseline characteristics. The χ^2 test was also used to evaluate the overall efficacy of the two treatments by comparison of the results of Papanicolaou smears and biopsy. Further comparison of the outcome of the treatments with covariate adjustments was performed with the "polytomous" logistic regression procedure.[18]

Results

A comparison of demographic characteristics, personal habits, sexual and reproductive history, and biochemical indices of nutritional status revealed that the placebo-treated group and the folic acid–supplemented group were suitably similar for statistical analysis. The population was from a lower socioeconomic group (mean annual family income $7740) and was 64% black and 36% white. The mean age was 25.0 years (14% <20 and 2% >40), and median level of formal education was 11.7 years. There was no significant difference between treatment categories with regard to age at first intercourse, parity, smoking habits, oral contraceptive use (80% current users), and rate of HPV-16 infection (30% positive). The single exception was that 46% of folic acid–supplemented subjects reported more than four sexual partners, compared with 32% in the placebo category ($p = 0.006$). A suitable adjustment was made for this difference in subsequent analyses. These laboratory indices at the initial visit were similar in the placebo-treated group and the folic acid–supplemented group: hematocrit, vitamin A (plasma retinol), plasma carotenoids, plasma ascorbate, plasma vitamin B_{12}, plasma folate, red blood cell folate, plasma zinc, red blood cell zinc, plasma copper, and the deoxyuridine suppression test.

An indication of compliance with the protocol may be derived from the number of subjects who returned for scheduled follow-up visits. Of 121 subjects assigned to receive folic acid, 108, 104, and 102 returned for appointments at 2, 4, and 6 months, respectively. All had colposcopic and cytologic evaluations at each visit, and 91 had a punch biopsy performed at the last visit; a biopsy was not considered necessary in 11 subjects. Of 114 subjects assigned to receive placebo, 98, 96, and 97 returned for appointments at 2, 4, and 6 months, respectively. They also had colposcopic and cytologic evaluations at each visit, and 86 had a punch biopsy at the last visit; a biopsy was not considered necessary in 11 subjects. Two hundred thirty-five subjects enrolled at the initial visit; of this number, 199 completed the 6-month evaluation. The dropout rate was 15.3%.

Initial red blood cell folate level (mean ± SE) for the subjects subsequently assigned to receive folic acid was 224 ± 32 ng/ml; the corresponding value for subjects assigned to receive the placebo was 234 ± 12 ng/ml. After 6 months of supplementation the red blood cell folate level was 753 ± 50 ng/ml in those who received the active material. The value remained essentially unchanged (254 ± 19) in the placebo group. Plasma ascorbate levels were not significantly affected by the placebo; they were 5.3 ± 0.3 ng/ml at the outset and 4.7 ± 0.4 ng/ml at the end of the trial period.

Fig. 1 displays the cumulative percentage changes in the red blood cell folate level of all subjects between initial and final visits according to treatment category (folic acid or placebo). A high degree of compliance is seen in the distribution pattern. Values in approximately 80% of the individuals assigned to receive placebo clustered around a zero change, and only eight subjects had an increase of >100% in red blood cell folate levels. It is not known if these subjects were taking self-administered supplements or if they had received active capsules in error. Subsequent analyses included comparison by levels of red blood cell folate and not merely by assignment to a category. In contrast, approximately 70% of the individuals assigned to receive active folic acid showed an increase of >100% in red blood cell folate levels; values in nine subjects increased ≥700% from baseline values.

Fig. 2 graphically illustrates the changes in Papanicolaou smear results from the initial visit to the last and the biopsy result according to treatment groups. No significant differences were observed for either outcome between subjects who had received folic acid and those who had received placebo. In the multivariate logistic regression analysis, initial Papanicolaou smear, race, and number of sexual partners were found to correlate significantly with the biopsy results. After adjustments for these three factors, the difference in biopsy results between the two treatment groups remains not statistically significant ($p = 0.833$). Although each subject had a visible colposcopic lesion and an abnormal Papanicolaou smear initially, >60% in each treatment group had normal biopsy specimens at the end of 6 months. The supplement was not accompanied by any evidence of worsening with regard to cytologic or biopsy results.

Table I presents the changes observed in HPV status of cervicovaginal scrapings between the initial visit and the final follow-up examination according to levels of red blood cell folate. A trend showing significantly more positive tests for HPV-16 was observed initially with lower levels of red blood cell folate ($p = 0.035$). The same basic patterns persisted after the 6-month period of supplementation, although the trend became only marginally significant ($p = 0.071$). There was a decline in lower values and an increase in higher values of red blood cell folate in the population as a result of changes in the supplemented group. Table I also pre-

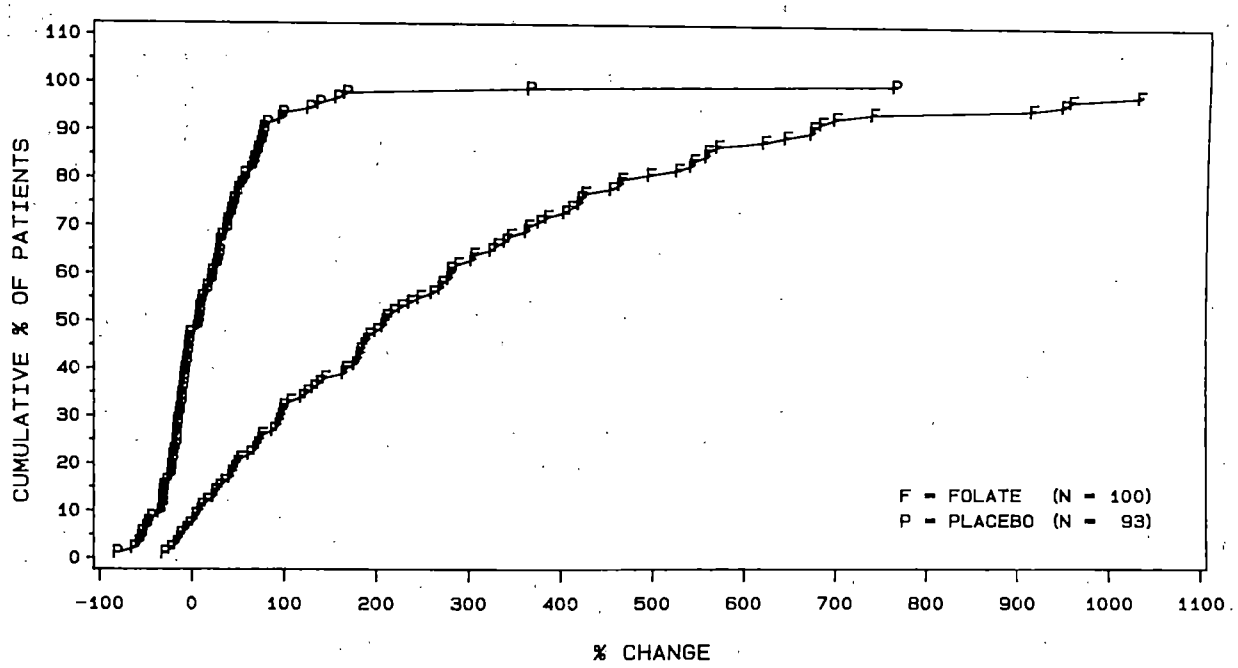

Fig. 1. Cumulative percentages of change over baseline in red blood cell folate concentration for subjects receiving folic acid supplement *(F)* and placebo *(P)*. Patterns clearly define separate populations and indicate high degree of compliance. It is possible that two individuals showing a high percentage of change in placebo group received active medication in error. Analysis of outcome included red blood cell folate status and was not limited to assigned category (see text).

Table I. Initial and final HPV-16 test results and number of positive biopsy findings (grades 1, 2, and 3 cervical intraepithelial neoplasia) according to upper, middle, and lower tertiles of red blood cell folate

The distribution of HPV-16–positive cases among all subjects according to three categories of red blood cell folate at the time of the initial evaluation *(top)* and again after the 6-month observation period *(middle)*. Although supplementation nearly doubled the number of individuals in the high folate category, the same basic trend persisted, but at a less significant level ($p = 0.071$). Also shown *(bottom)* is the distribution of positive biopsy findings (grades 1, 2, and 3 cervical intraepithelial neoplasia) according to categories of red blood cell folate for all subjects. The percentage of subjects with a positive biopsy finding was slightly greater with lower red blood cell folate levels, but the difference was not statistically significant.

sents the relationship of the biopsy classification to the final red blood cell folate status. All subjects who underwent biopsy are included whether they were assigned to receive the folic acid supplement or placebo. There were slightly more positive findings (i.e., grades 1, 2, and 3 cervical intraepithelial neoplasia) among subjects with lower red blood cell folate levels, but the difference was not statistically significant. Tabulation

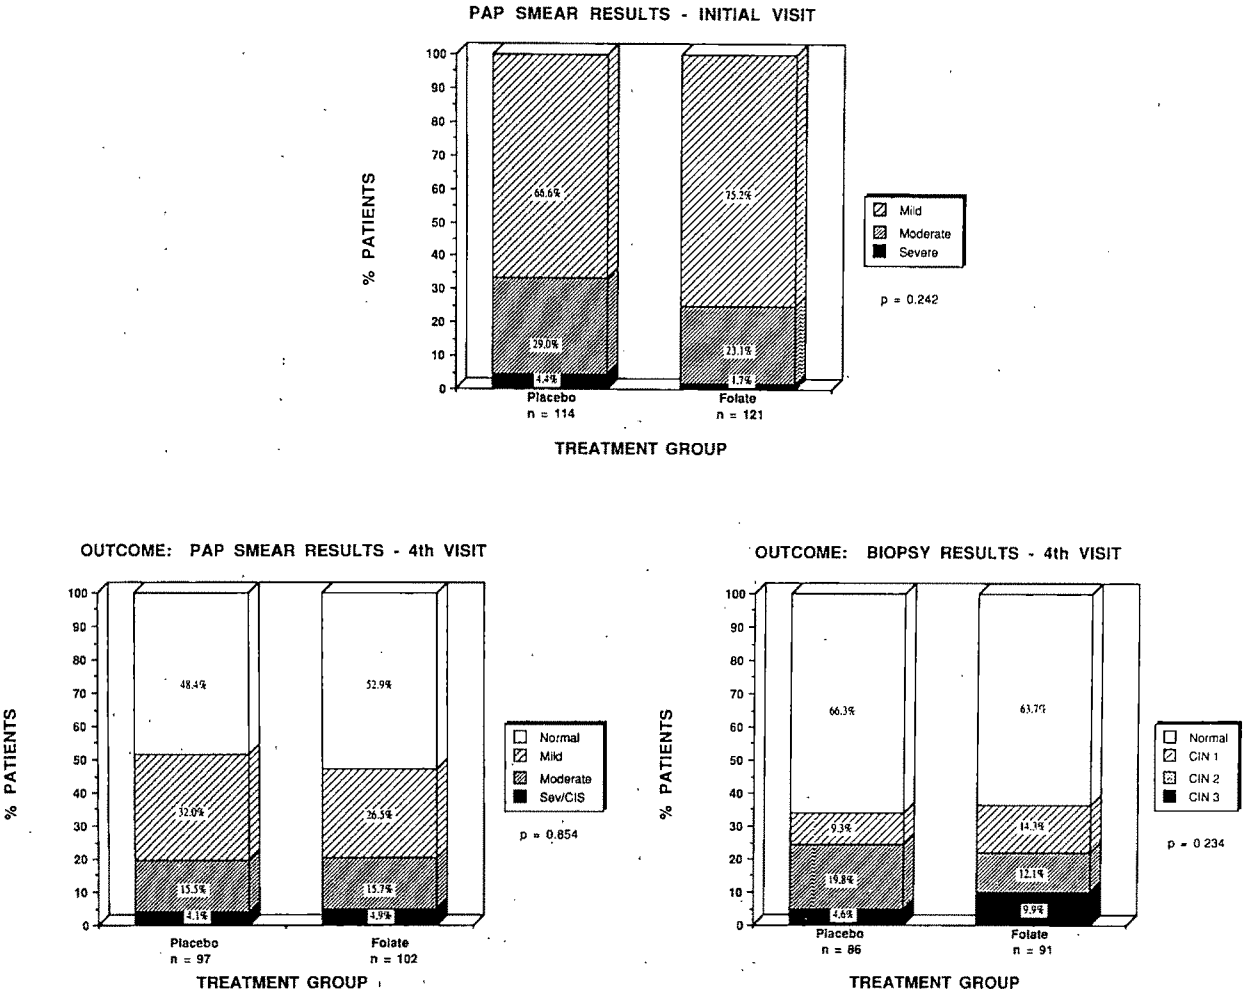

Fig. 2. *Upper panel* indicates similarity in distribution of cases according to severity of cytologic lesions for subjects randomly assigned to receive either placebo or folic acid supplementation. Only subjects with an abnormal Papanicolaou smear were entered into clinical trial. *Lower left panel,* Distribution of Papanicolaou smear results for two categories after 6 months of observation. There is no significant difference between outcome in placebo or folic acid–supplemented subjects ($p = 0.854$). *Lower right panel,* Biopsy results for two categories. There is no significant difference between population receiving placebo and those who received folic acid supplement ($p = 0.234$). After 6 months of observation approximately half of the entering subjects were normal according to Papanicolaou smear results and two thirds were normal according to biopsy results, regardless of treatment category.

of the same biopsy results according to the initial red blood cell folate levels (not shown) reveals essentially the same distribution pattern, with 31%, 33%, and 39% in the upper, middle, and lower tertiles, respectively.

Comment

This study was designed to test the hypothesis that high-dose oral supplements of folic acid will modify the course of cervical dysplasia and improve its cytologic and histologic manifestations. The findings reject the hypothesis but provide useful information that was not anticipated at the outset. At the time the project was planned, it was believed that a localized folate deficiency may exist in the cervix without evidence of systemic depletion. Also, the role of papillomaviruses was gaining recognition as an etiologic factor of cervical dysplasia, although this role was not well established. Our results, as well as those of a case-control study,[10a] indicate a higher prevalence of dysplasia associated with HPV-16 infection among women in the lower two tertiles of red blood cell folate than in the highest tertile. However, oral folic acid supplementation given over a period of 6 months appears to have no significant effects on the course of established cases of dysplasia. Possible explanations for the difference between the current findings and the earlier report[1] include a more adequate sample size, exclusion of patients classified as having atypia less than dysplasia, and a longer period of observation. We entertained the possibility that the 10 mg dose of ascorbate, which is generally regarded as trivial, might have had a therapeutic effect. However, this seems unlikely because plasma ascorbate levels

were not associated with dysplasia[10a] and they did not change in the subjects receiving placebo during the period of observation. Zeigler et al.[19] also found no significant differences in cervical cancer incidence associated with quartiles of ascorbate intake ranging from <93 mg/day to >212 mg/day.

The high rate of apparent regression in both the placebo-treated and folic acid–supplemented groups of our intervention trial (66.3% and 63.7%, respectively) may have contributed to the lack of significant differences. Although there are conflicting reports regarding rates of spontaneous regression, Nasiell et al.[20] observed a 62% rate of regression to normal among 555 women with mild dysplasia who underwent follow-up for an average of 39 months without major treatment.

In a review of the role of vitamin B_{12} and folate deficiencies in carcinogenesis, Eto and Krumdieck[21] observed that neither deficiency is carcinogenic by itself but that each may increase susceptibility to the action of other carcinogens. Folate deficiency is associated with chromosome breaks,[22] which can allow the insertion of viral oncogenes or can cause translocations with a resultant alteration in genetic regulatory mechanisms.[23] A deficiency of folate and related methyl donors has also been reported to enhance the expression of endogenous and exogenous oncogenes that might otherwise by suppressed.[7]

According to the concept of multiple stages in the process of carcinogenesis, the initiation phase of cervical intraepithelial neoplasia may begin when a genome of oncogenic HPV is incorporated into the host cell DNA. Nearly every human chromosome carries at least one protooncogene, and human tumor cells commonly have mutations that permit either the activation of oncogenes or the inactivation of tumor suppressor genes. Therefore enhanced expression of genetic information in the presence of sublethal folate deficiency or rearrangement of genetic sequences that result from folate-related chromosome breaks could initiate uncontrolled cell growth. There is evidence that in an established line of cultured cervical cancer cells the HPV-18 genome is present at a constant location on chromosome 12 and that insertion may have been facilitated by a folate-sensitive fragile site at the same location.[24] Thus folate deficiency could be a key factor in the initiation of cancer by an oncogenic strain of HPV.

In keeping with a study that compared these same cases of dysplasia with controls,[10a] the lowest rate of HPV-16 infection was observed in the group with the highest levels of red blood cell folate. A plausible explanation for these findings is that folate deficiency serves as a cocarcinogen in the presence of exposure to an oncogenic strain of HPV. After a viral genome has been incorporated into the host DNA, folic acid supplements have little or no effect on the course of the infection.

We thank the State Health Department, Dr. Claude Earl Fox, Health Officer, and the Central Alabama Public Health Region, Dr. Melinda G. Rowe, Health Officer, for their cooperation. We also thank Drs. R.D. Alvarez and Mark Potter for skilled patient management, Mrs. Shirley Hester and Mrs. Penelope Bosarge for nursing services, Dr. Hazel Gore and Ms. Kay Kuykendall for cytologic interpretations, and Ms. Linda Austin for data processing and analysis. We are grateful to Drs. Helmut Mueller, Bruce Stadel, and Robert Spirtas of the Contraceptive Evaluation Branch, Center for Population Research, National Institute of Child Health and Human Development, for their helpful suggestions during the developmental and implementation phases of this project. Mrs. Carol Craig and Ms. Nedra Wilson made generous contributions to study design and management of interview data.

Bound volumes available to subscribers

Bound volumes of the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY are available to subscribers (only) for the 1992 issues from the Publisher, at a cost of $68.00 for domestic, $95.76 for Canada, and $91.00 for international for Vol. 166 (January-June) and Vol. 167 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the JOURNAL name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, USA; phone (800) 325-4177, ext. 4351, or (314) 453-4351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular JOURNAL subscription.

Efficacy of the fetal-pelvic index in nulliparous women at high risk for fetal-pelvic disproportion

Mark A. Morgan, MD, and Gary R. Thurnau, MD
Oklahoma City, Oklahoma

OBJECTIVE: The null hypothesis of this study is that the fetal-pelvic index will not determine the presence or absence of fetal-pelvic disproportion in 137 nulliparous women at high risk for fetal-pelvic disproportion.
STUDY DESIGN: This study was undertaken by comparing the blinded fetal-pelvic index values and two other methods of identifying fetal-pelvic disproportion, ultrasonography-derived estimated fetal weight ≥4000 gm and Mengert's index, to delivery outcomes in 137 nulliparous women at high risk for fetal-pelvic disproportion.
RESULTS: After adequate labor trials, 55 of 73 patients who required operative intervention had a positive fetal-pelvic index (sensitivity = 75%). Seventeen of the 18 patients with a false-negative fetal-pelvic index value had persistent malpositions (15 occipitoposterior, 1 occipitotransverse, and 1 face presentation). Spontaneous vaginal deliveries occurred in 64 patients with 62 of them having a negative fetal-pelvic index (specificity 97%). The overall predictability of the fetal-pelvic index in this patient population was 85% and the positive predictability was 96%. However, neither ultrasonography-derived estimated fetal weight nor x-ray pelvimetry, when used alone, accurately detected the presence or absence of fetal-pelvic disproportion in nulliparous women at high risk for the condition.
CONCLUSION: The fetal-pelvic index is efficacious in determining the presence or absence of fetal-pelvic disproportion in nulliparous women at high risk for the condition. (Am J Obstet Gynecol 1992;166:810-4.)

Key words: Fetal-pelvic disproportion, fetal-pelvic index, nullipara, labor

The laboring nulliparous patient presents a unique situation to the obstetrician because her pelvis (passage) and her fetus (passenger) are about to have their first confrontation. The circumstance in which the fetus is too large to pass through the pelvis is defined as fetal-pelvic disproportion. Furthermore, for those patients in whom fetal-pelvic disproportion is present, maternal and perinatal morbidity and mortality rates are increased.[1-9]

Numerous methods to identify fetal-pelvic disproportion have been tested, including a clinical estimation of both the pelvis size and fetal weight, maternal radiographic pelvimetry,[10,11] ultrasonography-derived estimated fetal weight,[12] and simply a trial of labor for all cephalic presentations.[13] Although each of these methods has demonstrated limited success, none has proved reliable in prospectively diagnosing fetal-pelvic disproportion.

The fetal-pelvic index was introduced as a method of identifying both the presence and absence of fetal-pelvic disproportion, by comparing the respective fetal head and abdominal circumferences with the maternal inlet and midpelvic circumferences.[14] Although the fetal-pelvic index has proved to be a reliable method of determining fetal-pelvic disproportion in patients delivered of macrosomic neonates,[15] in those requiring labor inductions,[16] in those with abnormal labor patterns requiring augmentation,[17] and in those attempting vaginal birth after previous cesarean section,[18] the efficacy of the fetal-pelvic index in nulliparous patients at high risk for fetal-pelvic disproportion has not been determined. The objective of this study is to compare the efficacy of three methods used to identify fetal-pelvic disproportion, ultrasonography-derived estimated fetal weight ≥4000 gm, Mengert's index, and the fetal-pelvic index, in nulliparous women at high risk for fetal-pelvic disproportion.

Material and methods

One hundred sixty-four nulliparous women who were seen by the Oklahoma Memorial Hospital labor and delivery personnel at term gestation with either an unengaged fetal presentation, clinically suspected fetal macrosomia, a small maternal pelvis, or an indication for labor induction or augmentation were entered into this study (Table I). Twenty-seven patients were excluded from data analysis after undergoing an operative delivery before an adequate labor trial (four with suspected macrosomia—no labor trial, three positive

and one negative fetal-pelvic indexes; six with failed induction and cervical dilatation <4 cm, one positive and five negative fetal-pelvic indexes; four with breech presentation and no labor, three positive and one negative fetal-pelvic indexes; and one with persistent occipitoposterior presentation with fetal-pelvic index used in management) or because of fetal distress (12 patients with four positive and eight negative fetal-pelvic indexes). The remaining 137 patients had an adequate trial of labor, defined as uterine contractions of a frequency of at least three contractions in 10 minutes, an intensity of >50 mm Hg, and a duration of >60 seconds by an intrauterine pressure catheter and a cervical dilatation of ≥5 cm for a minimum of 2 hours. Spontaneous labor occurred in 55 patients, and 82 patients required oxytocin to stimulate labor (37 inductions, 45 augmentations).

Fetal ultrasonographic evaluations were performed in the labor rooms with a portable linar array ultrasonography machine. Diameters of the fetal head, transverse and anteroposterior, were determined by means of built-in electronic calipers applied to a freeze-frame image of the plane that included the thalamus, septum cavum pellucidum, and a symmetrically aligned midline echo. Diameters of the fetal abdomen, transverse and anteroposterior, were determined by means of built-in electronic calipers applied to a freeze-frame image of the plane perpendicular to the fetal spine at the level of the portal vein bifurcation and stomach.

Maternal pelvic measurements were obtained with the Colcher-Sussman x-ray pelvimetry technique.[11] This method consists of simple patient positioning so that lateral and anteroposterior views of the pelvis are obtained. A ruler is positioned to allow its inclusion on the radiograph for straightforward pelvic diameter measurement. Diameters of the inlet and midpelvis, transverse and anteroposterior, were measured before either the active phase of labor or oxytocin administration.

From the sites of individually measured diameters respective circumferences of the fetal head, fetal abdomen, maternal pelvic inlet, and maternal midpelvis were calculated with the simple equation: Circumference = (Transverse diameter + Anteroposterior diameter) × ½ π. On the basis of the four circumference differences between the fetus and maternal pelvis (head circumference − pelvic inlet circumference, head circumference − midpelvis circumference, abdominal circumference − pelvic inlet circumference, abdominal circumference − midpelvis circumference), a fetal-pelvic index value was derived from the sum of the two most positive circumference differences.[14] A positive fetal-pelvic index value indicates the fetus to be larger than the maternal pelvis, and a negative fetal-pelvic index value, the fetus to be smaller than the maternal pelvis. It is our hypothesis that a positive or negative fetal-pelvic index value indicates the presence or absence of fetal-pelvic disproportion, respectively. Results of the fetal-pelvic index values were blinded from the clinicians managing the patient's labor, and delivery outcome results were blinded from the investigators.

Table I. Patient population

Patient category	*No.*
Unengaged fetal presentation	34
Suspected small maternal pelvis	14
Suspected fetal macrosomia (>4000 gm)	7
Indications for induction	
Premature rupture of membranes	11
Postdates	9
Preeclampsia	9
Diabetes mellitus	5
Other	3
Labor pattern for augmentation	
Primary dysfunctional	12
Secondary arrest	20
Combined	13

The fetal-pelvic index and two other methods of identifying fetal-pelvic disproportion were compared with regard to both clinical outcome and the accuracy of predicting the presence or absence of fetal-pelvic disproportion. The two methods were ultrasonography-derived estimated fetal weights (tables of Shepard et al.[12]) with an estimated fetal weight of ≥4000 gm as the threshold weight for identifying the presence of fetal-pelvic disproportion and Mengert's index[10] of maternal pelvic area capacity with a contracted pelvis defined as <85% of average pelvic capacity, <123 cm^2 for the inlet or <106 cm^2 for the midpelvis.

This study was reviewed and approved by the institutional review board. Continuous data were reported as the mean ± SD and were analyzed with an independent two-tailed t test with categoric data being analyzed by χ^2 and Fisher exact test where appropriate. A p value of <0.05 was considered significant. An operative delivery was defined as either an operative vaginal delivery, in patients requiring a midpelvic instrumental delivery or an extra maneuver to reduce a shoulder dystocia and achieve delivery, or a cesarean section for the clinical diagnosis of failure to progress.

Results

After an adequate labor trial, 73 patients required operative intervention, 65 cesarean section and eight operative vaginal, to achieve delivery. Sixty-four patients had spontaneous vaginal deliveries. The mean maternal age and maximum dose of oxytocin were comparable between the groups (Table II). The frequency of those having spontaneous labor and those requiring oxytocin induction or augmentation of labor were similar between the groups. However, the mean gestational

age at delivery and birth weight were significantly greater in the operative delivery group compared with the spontaneous vaginal delivery group (Table II).

Although the mean fetal head circumferences were similar between the groups, the mean fetal abdominal circumferences were significantly larger in the operative delivery group (Table III). Interestingly, the mean maternal pelvic inlet and midpelvic circumferences in the operative delivery group were significantly smaller than those in the spontaneous vaginal delivery group. There was no classic cephalopelvic disproportion observed because the head circumferences between these two groups were similar and smaller than their respective maternal pelvic circumference measurements. On the basis of these measurement data, fetal-pelvic disproportion exists in the operative delivery group. The fetal measurement that appears to be indicative of fetal-pelvic disproportion is the fetal abdominal circumference, because this measurement in the operative delivery group was larger than its respective midpelvic circumference. However, the fetal abdominal circumference in the spontaneous vaginal delivery group was smaller than its respective maternal midpelvic circumference (Table III).

Of the 73 patients requiring operative intervention to achieve delivery, 55 had a positive fetal-pelvic index value, 50 cesarean and five operative vaginal deliveries, and 18 patients had negative fetal-pelvic index values for a sensitivity of 75% (Table IV). Of the five patients with a positive fetal-pelvic index who required operative vaginal deliveries, two patients had midforceps rotations, two patients had shoulder dystocias, both requiring McRobert's maneuver and suprapelvic pressure, and one patient had a midforceps rotation and shoulder dystocia requiring Wood's maneuver. The 18 patients with negative fetal-pelvic index values who required operative deliveries warrant further discussion. All 15 of those patients requiring cesarean section had persistent fetal malpositions, 14 occipitoposterior and one mentum posterior face presentation. In addition, two of the three patients who required operative vaginal deliveries with negative fetal-pelvic index values had persistent fetal malpositions, one occipitoposterior and one occipitotransverse. The third patient, who required midforceps delivery, had a dense epidural and maternal fatigue after a prolonged second stage of labor.

Sixty-four patients had spontaneous vaginal deliveries with 62 patients having negative fetal-pelvic index values for a specificity of 97% (Table IV). The two patients who were delivered vaginally with positive fetal-pelvic index values both had abdominal-pelvic circumference differences that contributed to their positive fetal-pelvic index values and one of these patients had outlet forceps performed. Overall, the delivery outcome predictability for the fetal-pelvic index was 85% and the positive predictability was 96%.

When the ultrasonography-derived estimated fetal weight was used alone with ≥4000 gm as the threshold weight for suspicion of fetal-pelvic disproportion, the

†Midforceps rotation, $n = 2$; shoulder dystocia, $n = 2$; midforceps rotation and shoulder dystocia, $n = 1$.

‡Persistent occipitoposterior, $n = 1$; persistent occipitotransverse, $n = 1$.

sensitivity was 22%, specificity 98%, and the overall predictability 58% (Table IV). With Mengert's index alone, with a contracted pelvis defined as <85% of average pelvic capacity area (<123 cm^2 for the inlet or <106 cm^2 for the midpelvis), the sensitivity was 30%, the specificity was 95%, and the overall predictability was 61% (Table III). Therefore neither of these techniques, when used alone, provided accurate identification of fetal-pelvic disproportion because of their respective low sensitivities.

Comment

The nulliparous patient in labor presents a unique challenge to the obstetrician because a fetus has not previously had to negotiate her pelvis. Friedman and Sachtleben,[1-3, 19] in a number of reports, described dysfunctional labor in the nulliparous patient and observed that fetal-pelvic disproportion was not uncommonly the cause, frequently resulting in prolonged labor trials.[3] The majority of these prolonged labor trials ended with an operative delivery, either midpelvic instrument assisted or cesarean section. The maternal and neonatal outcomes in these nulliparous women with prolonged labor trials as a result of fetal-pelvic disproportion are frequently adverse.[2, 3, 9]

Fetal-pelvic disproportion is not the result of dysfunctional labor but occurs when the passenger (fetus) is larger than its respective passage (maternal pelvis). Initially, radiographic pelvimetry was thought to be predictive of obstetric outcome. However, as the obstetrician began to have a more active role in treatment of dysfunctional labor, it was less useful and its use was discontinued.[13, 20, 21] Our study confirms the inability of x-ray pelvimetry, when used alone, to accurately predict the presence of fetal-pelvic disproportion (Table IV). Similarly, the predictability of an arbitrary ultrasonography-derived estimated fetal weight to detect the presence of fetal-pelvic disproportion, when used alone, is unacceptably low (Table IV).

Because attempts at measuring only the passage (maternal pelvis) have failed, it has been recommended that all patients with a cephalic presentation continue to labor until either vaginal delivery is accomplished or labor arrest is blatantly obvious.[13] With this approach an increase in the number of cesarean sections for dystocia has occurred without a determination of the size of the passage (maternal pelvis) and passenger (fetus). Although the philosophy that all women deserve a labor trial has been embraced with open arms, there still remains an increased rate of maternal postcesarean infectious morbidity[4-7] and an increased frequency of acidotic neonates in women with fetal-pelvic disproportion.[8] Therefore the prospective diagnosis of fetal-pelvic disproportion would seem helpful in these patients to avoid prolonged labor trials, which lead to an operative delivery.

The fetal-pelvic index allows the detection of the presence or absence of fetal-pelvic disproportion in the laboring nulliparous patient with a high degree of predictability (Table IV). The unique innovation of this concept is that the size of the passage (maternal pelvis) and the respective passenger (fetus) are compared rather than there being an exclusive investigation of the maternal pelvic size (passage) or the fetal weight (passenger). The overall predictability of the fetal-pelvic index that we observed in this study was similar to the overall predictabilities of the fetal-pelvic index previously reported in other high-risk patient groups.[14-18] The false-negative fetal-pelvic index values observed in this study, with one exception, were consistently due to the presence of persistent fetal malpositions. This type of malposition, occipitoposterior, has been previously observed to occur in nulliparous patients with dysfunctional labor and frequently requires an operative delivery in spite of oxytocin augmentation of labor.[1, 17]

The sensitivity, specificity, and overall predictability of the fetal-pelvic index of nulliparous women from the previous report of patients delivered of macrosomic neonates[15] were 86%, 100%, and 93%, respectively, and these values were 88%, 100%, and 96%, respectively, from women in this study delivered of macrosomic neonates. Similarly, the sensitivity, specificity, and overall

predictability of the fetal-pelvic index of nulliparous women from the previous report of patients requiring labor induction[16] were comparable to the rates of this study in patients who required labor induction (85%, 100%, and 93% vs 83%, 100%, and 92%). The efficacy of the fetal-pelvic index reported previously in nulliparous women requiring labor augmentation[17] was comparable to that of women in this study who required labor augmentation (sensitivity 73%, specificity 100%, and overall predictability 84% vs 67%, 94%, and 78%, respectively). Data generated from this study confirm our previous observations.[15-17]

Because many nulliparous women at high risk for fetal-pelvic disproportion often have prolonged, unsuccessful labor trials and have potential for morbidity,[1-3] we believe that the use of the fetal-pelvic index can alert the obstetrician of the patient in whom an earlier cesarean section during the labor trial may be beneficial. Conversely, reassurance of a vaginal delivery can be provided to both the obstetrician and the nulliparous women, with a negative fetal-pelvic index and without a fetal malposition. Before cesarean section is performed in nulliparous women without a trial of labor, a randomized trial comparing the maternal and perinatal morbidity of patients with a positive fetal-pelvic index who undergo a cesarean section without a labor trial with that of patients with a positive fetal-pelvic index, blinded from the care giver, who undergo a labor trial is needed. This type of study could verify the performance of a cesarean section without a labor trial in nulliparous women with a positive fetal-pelvic index who are at high risk for fetal-pelvic disproportion.

Superficial laser vulvectomy

V. Surgical debulking is enhanced by adjuvant systemic interferon

Richard Reid, MD,[a] Mitchell D. Greenberg, MD,[a] David J. Pizzuti, MD,[b] Katherine H. Omoto, MS,[a] Lisa H. Rutledge, BA,[c] and Whaijen Soo, MD, PhD[b]

Detroit and Southfield, Michigan, and Nutley, New Jersey

Skillful laser ablation can remove any volume of human papillomavirus–associated vulvar disease but cannot prevent reactivation of the surrounding latent viral reservoir during postoperative healing. Conversely, interferon and 5-fluorouracil are relatively ineffective as primary therapies in clearing bulky lesions. In this study of 71 assessable patients, topical 5-fluorouracil and systemic interferon injections were used postoperatively. Success rates within the adjuvant 5-fluorouracil and laser alone arms were essentially the same (9 of 18 vs 8 of 20). In contrast, outcome in the interferon group was significantly better than that for the other two arms combined (27 of 33 [82%] vs 17 of 38 [45%]; χ^2 10.31; $p < 0.002$). Moreover, 18 of 21 failures (86%) in the first two arms and 3 of 6 failures (50%) in the interferon arm were "rescued" from the need for a second laser surgical procedure by crossover to either the 1 or 3 MIU interferon regimen. Results from this open-label, randomized clinical trial suggest that even a relatively low dose of recombinant interferon, used in combination with effective surgical debulking, can markedly reduce the risk of postoperative recurrence. (Am J Obstet Gynecol 1992;166:815-20.)

Key words: Human papillomavirus vulvar disease, carbon dioxide laser, adjuvant interferon, topical 5-fluorouracil

Historically refractory condylomas and bowenoid dysplasia were managed by prolonged courses of topical 5-fluorouracil cream, in doses that produced widespread cytotoxicity and consequent epithelial sloughing.[1] However, such regimens were extremely painful and had low patient compliance. With the exception of isolated vaginal condylomas, destruction of macroscopic disease foci is better done with the carbon dioxide laser. However, the use of 5-fluorouracil in noncytotoxic doses has had a recent resurgence in modern clinical practice. Sillman and Sedlis[2] have shown, in patients with renal allografts or other immune deficiencies, that the use of lifelong low-dose 5-fluorouracil is an essential prerequisite to disease control. Krebs[3] extended this concept to the treatment of immunologically competent women, reporting improved success (87% vs 62%) in a group randomized to receive biweekly topical 5-fluorouracil as an adjunct to destructive therapy. However, in a retrospective review of 160 women treated primarily by extended laser ablation, we found that the beneficial effects of adjuvant, once-weekly 5-fluorouracil were limited to women with two or more adverse factors (i.e., cigarette smoking, impaired host immune status, high-risk viral type, high-grade dysplastic change, prolonged refractory clinical course, or failed previous extended laser ablation) (88% vs 56%).[4] Unfortunately, in our hands, low-dose 5-fluorouracil has added almost nothing (93% vs 87%) to the efficacy of destructive therapy in less complicated cases.

Over the last 10 years, various cytokines (compounds that regulate the activity of neighboring cells) have been tested for antiviral or immunomodulatory properties. In 1957, preliminary studies recognized the presence of an inducible, nondialyzable factor that protected eukaryotic cells in tissue culture against viral infection.[5] This factor has since been identified as interferon, a group of relatively species-specific glycoproteins with antiviral, antiproliferative, and immunomodulatory properties. Human interferons are classified into three classes (alpha, beta, and gamma), on the basis of antigenic specificity and cell of origin. Pharmacologic preparations came from two sources: natural (a mixture of predominantly alpha interferons obtained by partial purification of virus-stimulated buffy coat leukocytes) and recombinant (a single species of alpha, beta, or gamma interferons harvested by transfection of *Escherichia coli* colonies with plasmids containing the appropriate human genomic sequences). Biologic activity depends on specific cell surface receptors and is mediated through production of chromographically detectable proteins. Much of the antiviral activity is due to the induction of 2′5′-oligoadenylate synthetase, an

intracellular enzyme that degrades viral messenger ribonucleic acid, thereby terminating virus replication. Additional antiviral properties are conferred by the induction of protein kinase activity, resulting in the inactivation of cellular factors (such as eukaryotic initiation factor 2) required for the synthesis of viral proteins.[5] Immunomodulatory and antiproliferative properties are mediated through the enhancement of cytotoxic T cells, natural killer cells, antibody-dependent, cell-mediated cytotoxicity, and macrophage activity. Interferon exposure also increases expression of the histocompatibility markers at the cell surface, thereby improving host recognition of virus-infected cells.

All classes of interferon have known activity against papillomaviruses in vivo and in vitro. In tissue culture, natural lymphoblastoid interferon will protect mouse cells against infection with bovine papillomavirus and can also cure infected cells by eliminating the extra chromosomal viral deoxyribonucleic acid.[6] In vivo, clinical experience has confirmed that alpha,[7, 8] beta,[9] and gamma[10] interferons all display definite, albeit unpredictable, activity against expressed human papilloma-

virus infection. Unfortunately, comparison of these studies is impossible because of enormous variations in study design, patient selection, routes of administration, and dosage schedules. Nonetheless, attempts to use interferon as primary therapy have been disappointing,[11] and it is doubtful if the results achieved to date justify the expense, inconvenience, and morbidity of the various regimens used.[12] In this regard, seeking to clear large volumes of virally induced lesions with a drug may be analogous to attempting chemotherapy in advanced ovarian cancer, without prior cytoreductive surgery. This study seeks to evaluate two candidate regimens (5-fluorouracil and interferon) as adjuvants to optimally performed laser surgery in the treatment of confluent, refractory, or dysplastic vulvar disease.

Material and methods

Subjects for this single-center, randomized, open-label trial were adult women with human papillomavirus–associated vulvar disease of sufficient severity to warrant extended laser ablation (Figs. 1 and 2). Patients were recruited from women referred to the private practice of R.R. in Southfield, Michigan, between December 1987 and March 1989. Eligibility reflected three clinical categories: extensive coalescent benign condylomas, condylomas refractory to at least 9 months of simpler therapies, and extensive multifocal vulvar intraepithelial neoplasia (grade 2 or 3). Reasons for exclusion were the presence of a confounding dermatologic disease; a previous invasive malignancy; positive human immunodeficiency virus antibody test; significant renal, hematologic, cardiologic, pulmonary, or hepatic disease; nonavailability for follow-up; or any previous used interferon for any reason. After enrollment, patients were randomized to one of three treatment arms: extended laser ablation alone, extended laser ablation plus once-weekly topical 5-fluorouracil to the vulvar skin for 26 weeks, or extended laser ablation plus 1 MIU recombinant alpha interferon (Roferon A, Hoffman-La Roche, Inc., Nutley, N.J.), given by thrice-weekly self-administered subcutaneous injections in the anterior thigh for 10 weeks (Fig. 3). Patients then underwent follow-up at weekly intervals for the first month, at bimonthly intervals for the next 2 months, and every 3 months thereafter.

Minor focal recurrences were managed by ablation in the office, usually with application of 85% trichloracetic acid. Patients with treatment failure from arms 1 and 2 were commenced on a regimen of 1 MIU thrice weekly for 10 weeks and those from arm 3 were in-

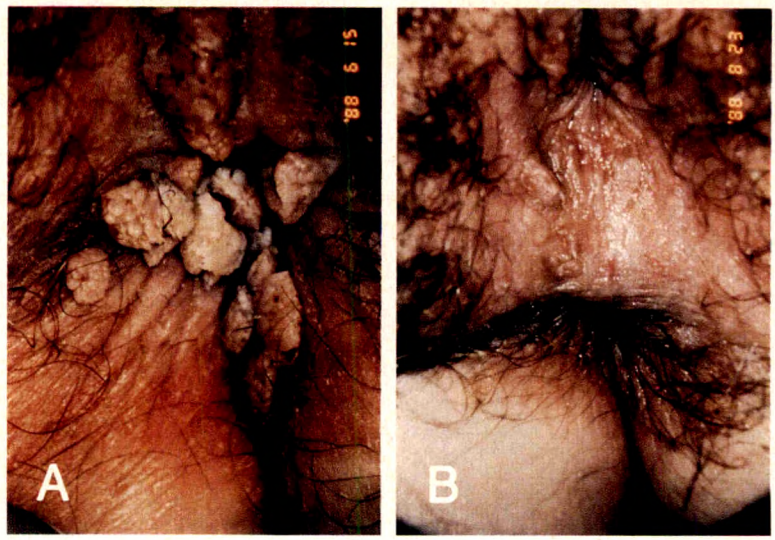

Fig. 4. A, Extensive condylomas have recurred by fourth postoperative week in patient initially treated by laser ablation alone. **B,** Complete response after crossover to 10 weeks of 1 MIU interferon plus adjuvant topical 5-fluorouracil.

$\chi^2 = 10.31$; $p < 0.002$ for interferon versus 5-fluorouracil–laser alone.

creased to 3 MIU interferon on the same dosage schedule. In this report results from the evaluable cases have been compiled into a contingency table reflecting status at the 18-month anniversary of surgery. Differences between regimens were analyzed by the χ^2 test.

Results

Eighty-four patients were originally scheduled with intent to treat: 26 in the untreated group, 29 in the 5-fluorouracil group, and 29 in the interferon group. However, between the time of constructing the randomization schedule and the time of actual surgery, two events arose to make it unethical to continue with the original intention to use 5-fluorouracil. First, analysis of historic data had already demonstrated that topical 5-fluorouracil was not an effective adjuvant, except in the presence of multiple risk factors.[4] Second, because of two case reports (Hoffmann-La Roche, Inc., data on file) of congenital malformations associated with intrauterine exposure to topical 5-fluorouracil, the Federal Drug Administration reclassified this drug as Category X (unsuitable for use in women of childbearing age). Consequently, 6 patients slated to receive adjuvant 5-fluorouracil received adjuvant interferon instead. Hence the final composition was 26 in the untreated group, 23 in the 5-fluorouracil group, and 35 in the interferon group.

After enrollment, 13 women were excluded: 3 for spontaneous regression before laser surgery and 10 due to protocol violations. This left 71 evaluable patients, 20 in the untreated arm, 18 in the 5-fluorouracil arm, and 33 in the interferon arm. Among the initially randomized patients, there were no significant differences with respect to mean age, age at first intercourse, number of sexual partners, duration of disease expression, number of anatomic sites involved, or number of adverse prognostic factors. At assessment of final outcome, it was found that 27 of 33 (82%) assessable patients in the adjuvant interferon arm were controlled by a single laser ablation, as compared with only 9 of 18 (50%) in the 5-fluorouracil group and 8 of 20 (40%) in the laser alone group (Table I). There was no statistical difference in outcome within the 5-fluorouracil and laser only arms. In contrast to 5-fluorouracil and laser alone, adjuvant interferon conferred a statistically significant protection against the frequency of postoperative recurrence (χ^2 10.31, $p < 0.002$). Moreover, we did not observe any side effects outside of the expected experience (i.e., some complaints of headaches and flulike symptoms).

Crossover of the 21 failures from arms 1 and 2 (to 1 MIU interferon and weekly 5-fluorouracil) secured complete regression in 18 (86%) instances (Fig. 4, Table II). Crossover to 3 MIU controlled 3 of the 6 failures

(50%) in arm 3. Although firm scientific inference cannot be drawn from these data, the need for further surgery in only 6 of these 27 failures (22%) stands in market contrast to our experience before the ready availability of interferon. Among the 160 patients treated between 1983 and 1987, 44 of 53 with initial failure (83%) required a second or third laser ablation.[4]

Comment

Large expanses of dermis can be safely removed with the carbon dioxide laser, with healing occurring by outgrowth from the underlying skin appendages rather than ingrowth from the wound edges.[13] Simultaneous removal of both the macroscopic papillomas and adjacent subclinical reservoir has produced the best results reported so far, controlling disease among 94% of the 160 most difficult referrals seen between 1982 and 1987.[4] However, the need for a second laser procedure in at least one third of the treated subjects speaks to both the strength and weakness of the carbon dioxide laser. The strength is that, used skillfully, the laser can remove any volume of diseased tissue under fine control, with an assurance of rapid healing and an absence of scarring. However, the weakness is that the laser cannot prevent reactivation of the latent viral reservoir within the adjacent skin during the postoperative healing phase. Hence the preliminary results from this open-label, randomized trial herald an important advance in the therapy of problematic human papillomavirus–associated vulvar disease. Used in conjunction with effective surgical debulking, adjuvant low-dose systemic interferon conferred a two-thirds reduction in postoperative recurrence during the first 6 months after extended laser ablation. In contrast, there was no protective effect attributable to the use of adjuvant 5-fluorouracil. It appears that the combination of skilled laser surgery plus adjuvant systemic interferon does produce results superior to those attainable by either laser alone or laser with adjuvant 5-fluorouracil.

Unlike the clear-cut efficacy of interferon when used in combination with surgery, it has been difficult to establish the value of this drug as a primary therapy. An effective topical regimen would provide local delivery without systemic toxicity. In spite of initial claims of a 90% complete response rate with natural leukocyte interferon ointment,[5] subsequent studies could not even confirm that topical preparations had biologic activity.[14] Intralesional administration does have a reproducible capacity to produce regression of injected warts while avoiding most systemic side effects.[15] However, success rates of intralesional regimens have been modest, perhaps no better than what could have been achieved by local destruction.[12] Moreover, the practicality of such regimens remains doubtful. Only a few papillomas can be injected during one course of treatment, and there is no effect on either uninjected lesions or the subclinical reservoir. In contrast, intramuscular and subcutaneous regimens have documented activity in extensive and refractory disease. In two small, open-label, noncomparative, dose-response studies, Gall et al.[7, 8] obtained complete response rates of up to 90% with doses of 5 MIU/m², albeit at a substantial cost in morbidity. All patients in the 5 MIU/m² category required dosage reduction because of the severity of side effects. Unfortunately, double-blind, placebo-controlled trials with better tolerated doses have been unable to replicate the complete resolution rates seen in earlier trials.[11] Although remarkable improvements can occur in selected patients, the predictability and durability of response as single agents have been disappointing. Moreover, about 20% of responders will experience relapse after discontinuing therapy. Although human papillomaviruses are the verified cause of a group of epithelial proliferations that sometimes progress to malignancy, the exact role that this relationship plays in the pathogenesis of invasive anogenital cancer is still uncertain.[16] Pending clarification of the high rate of latent infection among apparently healthy women, some have argued against the aggressive treatment of genital condylomas. However, we feel that the prevalence and distress occasioned by sexually transmitted human papillomavirus infection justify the treatment of this disease in its own right. Whereas stable clinical control is generally attainable with simple methods, there is a real need for an effective adjunct to laser ablation for difficult-to-manage cases. Whether 1 MIU represents the optimal choice of dosage requires further investigation.

Therapeutic amniocentesis in twin-twin transfusion syndrome appearing in the second trimester of pregnancy

N.J. Saunders, MD, R.J.M. Snijders, MSc, and K.H. Nicolaides, MD

London, England

Amniocentesis and drainage were performed in 19 twin pregnancies initially seen at <28 weeks' gestation with acute polyhydramnios caused by the twin-twin transfusion syndrome. The procedure was performed an average of three times for each patient (range one to six), with the removal of a mean volume of amniotic fluid of 2600 ml on each occasion (range 500 to 6700 ml). The interval between initial examination and delivery averaged 7 weeks (range 1 day to 18 weeks); 14 (37%) of the 38 babies survived the neonatal period. In the pregnancies with poor outcomes, the intertwin disparity in fetal size and the mean volume of amniotic fluid drained at each amniocentesis were greater than in the pregnancies in which one or both twins survived. (Am J Obstet Gynecol 1992;166:820-4.)

In twin pregnancies with presumed twin-twin transfusion syndrome, development of acute polyhydramnios at <28 weeks' gestation is associated with a high perinatal mortality rate, primarily because of spontaneous abortion or very premature delivery of growth-retarded babies or babies with hydrops. In an analysis

of 51 such published cases in which no antenatal intervention was undertaken, only five babies survived (Table I). Several reports on a small number of patients have suggested that outcome may be improved by repeated amniocenteses; therefore during the last 3 years a systematic prospective study was undertaken to examine the possible efficacy of this approach.

Patients and methods

During a 3-year period (1988 to 1990) 27 twin pregnancies with polyhydramnios at <28 weeks' gestation were referred to our unit for prenatal diagnosis and management. Ultrasonographic examination demonstrated that the fetuses were discordant in size and were separated by a thin membrane; there was a single placenta. In each case the larger twin was surrounded by polyhydramnios and appeared to have a distended bladder. The smaller twin appeared to be fixed to the placenta because of oligohydramnios, and no bladder could be found.[22]

In five cases one of the twins was dead at initial examination, and the surviving cotwin had either ventriculomegaly ($n = 1$) or hydrops ($n = 2$) or was normal ($n = 2$). The outcome of these pregnancies is shown in Table II. In another case initially seen at 21 weeks the recipient twin was normal, but the donor had ventriculomegaly. The pregnancy was managed conservatively and resulted in a spontaneous abortion at 22 weeks. Postmortem examination demonstrated intraventricular hemorrhage in the donor twin.

In the remaining 21 patients both fetuses were normal. The parents were counseled as to the likely poor prognosis and offered the options of conservative management, decompression amniocentesis, or termination of pregnancy. One patient opted for conservative management and miscarried 1 week after examination; another requested termination of pregnancy. The other 19 patients consented to serial amniocenteses. Ultrasonographically guided amniocentesis was performed with an 18-gauge needle, and amniotic fluid was al-

lowed to drain freely into a sterile bag through a plastic tube attached to the hub of the needle. In each case 500 to 6700 ml was drained over a period of 40 to 120 minutes until there was subjective normalization of amniotic fluid volume on ultrasonographic examination. Patients were assessed every week; if they had symptoms or if the abdomen was considered to be tense on palpation, further drainage was performed.

Results

For the 19 patients who had amniocentesis, the gestation at examination, volume of amniotic fluid drained, and outcome are summarized in Table III. The mean gestation at initial examination was 21 weeks 5 days (range 17 to 25). Amniocenteses were performed one to six times (mean three) with the average removal of 2600 ml of amniotic fluid at each tap (range 500 to 6700 ml). The mean interval between initial examination and delivery was 6.5 weeks (range 1 day to 18 weeks).

Four patients (Table III; cases 1 through 4) aborted spontaneously within 48 hours of the first or second drainage procedures. In six patients (Table III; cases 5 through 10), amniocentesis and relief of polyhydramnios were assoicated with prolongation of pregnancy by 2 to 9 weeks, but either both babies died in utero or the death of one fetus was associated with deterioration in the condition of the second twin, who was delivered but died in the neonatal period. In four cases (Table III; cases 11 to 14) one infant survived, but the other twin died either in utero or in the neonatal period. In five cases (Table III; cases 15 to 19) both babies survived the neonatal period; one infant died at the age of 6 months.

The mean gestational age at initial examination in the nine pregnancies in which at least one child survived (21^{+3} weeks) was similar to that of the 10 pregnancies in which both twins died (21^{+6} weeks). However, unsuccessful pregnancies were associated with a greater intertwin disparity in abdominal circumference at initial examination (Fig. 1; 33% compared with 15% in successful pregnancies). Furthermore, in pregnancies with poor outcomes the mean volume of amniotic fluid removed at each procedure was higher (3200 ml compared with 2300 ml in successful pregnancies).

Comment

In twin pregnancies with acute second-trimester polyhydramnios treated by amniocentesis the overall fetal survival rate of 37% compares favorably with the results of series in which there was no antenatal intervention (Table I). The most likely mechanism by which decompression amniocentesis may improve survival is by prolongation of pregnancy through prevention of the polyhydramnios-mediated risk of spontaneous abortion or very premature delivery. It is also possible that with advancing gestation and increasing fetoplacental blood volume the relative significance of the hemodynamic effects of placental anastomoses is reduced. In this respect repeated amniocenteses may, at least in

some cases, allow the fetal cardiovascular system to outgrow the deleterious effect of placental anastomosis.[22]

These data challenge the assertion that in twin-twin transfusion syndrome the need for decompression is a poor prognostic feature and that treatment by amniocentesis adds nothing to the management of this condition.[1, 9] However, the apparent beneficial effect of decompression amniocentesis may merely reflect differences in reported study populations. Thus retrospective studies on the conservative management of twin-twin transfusion syndrome often use the criterion of a major disparity in fetal weight to identify the population from hospital records. In contrast, prospective intervention studies tend to select patients purely on the basis of polyhydramnios, and the issue of disparity in fetal weight is generally dealt with in a less stringent manner. Our data indicate that the greater the disparity in size between twins at initial examination the worse the prognosis. The reported outcome of conservative management is poorer than that of interventional management (Table I); the difference may be partly explained by the inclusion of pregnancies with larger intertwin differences in the conservatively managed group. This, coupled with the phenomenon of reporting bias (a greater likelihood to publish cases in which intervention appeared to be successful) may have exaggerated the apparent advantages of treatment.

The association between poor outcome and large intertwin differences in size and the need for drainage of larger volumes of amniotic fluid is presumably a consequence of the severity of the underlying disease. Twin-twin transfusion syndrome is traditionally believed to be caused by the unbalanced shunting of blood from donor to recipient, resulting in anemia and polycythemia, respectively. However, fetal blood sampling by cordocentesis has recently demonstrated that there are no major intertwin differences in hemoglobin concentration, and an alternative hypothesis has been suggested regarding the pathogenesis of this condition.[23] Both the severe early onset growth retardation in the donor and the polyhydramnios in the recipient twin may be consequences of uteroplacental insufficiency affecting the donor twin. Increased peripheral resistance in the placental circulation of the donor twin would promote the shunting of blood to the recipient twin through the vascular anastomoses that are invariably present in all monochorionic twin pregnancies.[24] The recipient twin is able to dispose of the additional fluid load by increased urine production,[22] but the protein and cellular components remain in its circulation to create an increase in colloid osmotic pressure that causes water to move from the maternal compartment across the placenta. Thus volume overload and diuresis continue, and a vicious cycle is established. The more severe the uteroplacental insufficiency, the earlier the appearance of symptoms, the smaller the donor twin, the larger the intertwin disparity in size, the worse the polyhydramnios, and the poorer the prognosis.

Increased intrauterine pressure as a consequence of marked polyhydramnios would be expected to compromise the placental circulation further. Since we analyzed our results, Elliott et al.[25] have reported a perinatal survival rate of 79% in twin-twin transfusion syndrome treated with repeated amniocenteses; they

attribute the high survival rate to improved placental blood flow after decompression.[25] The lower rate of fetal salvage in our series may be caused by differences in the two study populations because the treatment protocols appear to have been similar.

Selective feticide has been suggested as an alternative form of therapy in twin-twin transfusion syndrome.[26] Spontaneous intrauterine death of one twin may to some extent represent a parallel situation with regard to the likely outcome in the surviving fetus. In three of the five cases in our series in which one fetus was dead at the time of initial examination at 21 to 27 weeks' gestation, there was gradual resolution in polyhydramnios and the healthy cotwins were born 9 to 12 weeks later; in one case hydropic changes resolved in the weeks after initial examination (Table II). However, in another two cases the surviving twin developed ventriculomegaly. Although cerebral damage in surviving twins has been attributed to disseminated intravascular coagulation after the release of thromboplastin from the dead twin, this may not be the underlying mechanism in all cases; we have also observed ventriculomegaly caused by intraventricular hemorrhage in one donor fetus while both twins were alive. In five of the pregnancies treated with amniocentesis one of the fetuses died; in none of these cases was there an obvious improvement in either the polyhydramnios or the condition of the surviving twin. Indeed, in three cases the condition of the other twin deteriorated, and the baby died either in utero or in the neonatal period.

Laser occlusion of placental anastomosis[27] may convincingly be shown to improve the outcome of twin-twin transfusion syndrome appearing in the second trimester of pregnancy. In the meantime, we recommend decompression amniocentesis as an easy and relatively safe option providing some hope in an otherwise hopeless situation.[10] Nevertheless, the value of such treatment can only be established if factors of prognostic significance are clearly defined. Intertwin disparity in abdominal circumference at initial examination appears to be one such factor and should be taken into account when considering the apparent efficacy of therapy.

Immunohistochemical detection of the multi-drug-resistance marker P-glycoprotein in uterine cervical carcinomas and normal cervical tissue

José Schneider, PhD,[a] Thomas Efferth, PhD,[b] Jürgen Mattern, MD,[b] Francisco-Javier Rodriguez-Escudero, PhD,[a] and Manfred Volm, PhD[b]

Bilbao, Spain, and Heidelberg, Germany

Uterine cervical carcinomas and normal cervical tissue (controls) were investigated for the presence of the multi-drug-resistance gene product P-glycoprotein by means of immunohistochemistry, with the C219 monoclonal antibody and the streptavidin-biotin-peroxidase technique. Ten of 11 cervical carcinomas, 2 of which were previously treated with chemotherapeutic agents of the multi-drug-resistance group, showed a positive reaction of tumor cells. All normal controls showed a positive reaction of the ectocervical and endocervical epithelial cells. P-Glycoprotein seems to be implicated at least in part in resistance to chemotherapy of cervical carcinoma. (Am J Obstet Gynecol 1992;166:825-9.)

Key words: P-Glycoprotein, carcinoma, uterus, cervix

The multi-drug-resistance phenotype is characterized by tumors exhibiting cross-resistance toward a variety of pharmacologically unrelated chemotherapeutic compounds. Among these are the anthracyclines (doxorubicin, its derivatives, and daunorubicin), the vinca alkaloids (vincristine and vinblastine), the podophyllotoxins (etoposide and teniposide), actinomycin D, and colchicine, most of which are widely used in clinical practice.[1-3] Multidrug resistance can be elicited in experimental tumors in vitro by exposing them to just one of the agents cited above; tumor cells frequently become cross-resistant toward the complete set of these drugs.[4] Multidrug resistance is associated with the overexpression of a membrane pump, called P-glycoprotein or P-170, because of its molecular weight of approximately 170 kd, which actively extrudes chemotherapy in a nonspecific fashion from the interior of the cell.[5] The involvement of P-glycoprotein in the development of the multi-drug-resistance phenotype has been convincingly demonstrated by the conversion of sensitive cells into multi-drug-resistant ones by transfection of the gene encoding P-170.[6] In humans it is known that tumors arising on organs with high intrinsic levels of P-glycoprotein, such as the kidney, colon, or liver, are also highly chemoresistant, not only toward chemotherapy belonging to the multi-drug-resistance family but to virtually any form of chemotherapy.[1-3]

An association between increased P-glycoprotein expression and development of resistance to therapy, analogous to the one extensively studied in experimental tumors, has been demonstrated in clinical specimens. These include gynecologic tumors, such as those found in the ovary,[7, 8] We have recently reported that endometrial carcinoma, which is somewhat refractory to conventional chemotherapeutic treatment, expresses P-glycoprotein at demonstrable levels before treatment.[9] Chemotherapy is being used increasingly in cervical carcinoma, not only for treatment of advanced disease but also as neoadjuvant therapy in operable cases.[10, 11] Many of the agents used for this purpose belong to the multi-drug-resistance class. Thus it would seem pertinent to analyze cervical carcinoma for the expression of P-glycoprotein. Therefore we studied a series of treated and untreated cervical carcinoma specimens, together with normal cervical tissue as a control, with immunohistochemistry, a method we have found useful previously in mammary, endometrial, and ovarian carcinomas.[9, 12]

Material and methods

Eleven cervical carcinomas and 10 normal controls were analyzed for the expression of P-glycoprotein. The specimens were obtained from patients of the Department of Obstetrics and Gynecology of the University Clinic (Hospital de Cruces) of Bilbao, Spain, either at biopsy or at the time of operation. Two patients received two and three courses, respectively, of polychemotherapy containing vincristine, a member of the multi-drug-resistance family, before the tumor material

was obtained. The clinical characteristics of the patients and histologic data of the tumors are summarized in Table I.

Immunohistochemistry (streptavidin-biotin-peroxidase method) was performed with the C219 monoclonal antibody originally developed by Kartner et al.,[13] which recognizes an epitope of P-glycoprotein located on the inner side of the cell membrane. The technical details have been described extensively elsewhere.[9, 12] Briefly, the specimens were immediately snap-frozen in liquid nitrogen at the time of surgery or biopsy and stored at −70° C until processed. Cryostat sections, 6 μm thick, were then made and fixed in cold acetone at −20° C for 10 minutes. The sections were rehydrated in phosphate-buffered saline solution, then incubated with normal serum from the same species that the second, bridge antibody is derived from, for the blocking of nonspecific binding. The monoclonal first antibody (C219, Centocor, Malvern, Pa.) was applied at concentrations varying from 2.5 to 10 μg/ml and incubated overnight at 4° C. The best results were obtained at a concentration of 10 μg/ml. The second biotinylated antimouse antibody (1:50) and the streptavidin-biotinylated-peroxidase complex (1:100) were applied in successive steps. Staining was done with 3-amino-9-ethylcarbazole, giving a red reaction product. The preparations were finally counterstained with Mayer's hematoxylin and mounted with glycerol gelatin. Negative controls for each sample were carried in parallel by incubation with normal mouse serum in substitution for the first antibody at the same concentration, and the rest of the procedure was carried out as described. As positive controls we used doxorubicin-resistant sarcoma-180 cell smears and preparations from a solid sarcoma-180 xenograft resistant to daunorubicin, expressing high levels of P-glycoprotein.[4]

Results

Of the 11 cervical carcinomas studied, 10 showed a clearly positive P-glycoprotein reactivity (Table I). The intensity of the reaction varied among four different grades: no reaction (−), one squamous carcinoma; discernible but lower than the one found in the positive controls (+), four squamous carcinomas and one adenocarcinoma; high, comparable to that of the positive controls (+ +), two squamous carcinomas (Fig. 1, *A*), one adenosquamous carcinoma (Fig. 1, *C*), and one adenocarcinoma; extremely high, i.e., stronger than the positive controls (+ + +), one case of minimal deviation adenocarcinoma, or "adenoma malignum" (Fig. 2, *A*). Both cases previously treated with polychemotherapy containing vincristine, a drug of the multi-drug-resis-

tance family, belonged to the second group, with a high reactivity (++). As to the distribution of positive cells (Table I), three of the 10 positive cases had only between 5% and 20% positive cells, whereas the remaining seven cases showed reactivity in >20% of the tumor cells. Of these, in the case of minimal deviation adenocarcinoma (tumor No. 11) with an immunohistochemical reaction of higher intensity than the controls (+++), virtually 100% of the tumor cells were positive (Fig. 2, *A*).

Both the ectocervical squamous and the endocervical glandular epithelium of the normal cervical specimens from the control group (Figs. 2, *C*, and 3, *A*) were reactive with the C219 monoclonal antibody (Table II). The reaction showed the same variations in intensity as described for the tumors. The distribution, however, was more uniform than the one that was observed in tumors, all endocervical glands (Fig. 2, *C*) and >20% of ectocervical cells (Fig. 3, *A*) being positive in all cases.

Comment

The results of this series seem to indicate that P-glycoprotein is expressed in a high number of cervical carcinomas. We found it present in 10 of 11 cases studied, regardless of the histologic type. P-Glycoprotein was also detected on the epithelium of all normal cervical controls, both on the endocervical glands, which

expressed it at very high levels, and on the squamous epithelium of the ectocervix. Riou et al.,[14] by means of molecular biology, recently investigated the content of messenger ribonucleic acid (mRNA) encoding P-glycoprotein in cervical carcinoma and normal cervical epithelia. They found elevated levels in 88% of treated carcinomas, 69% of adenocarcinomas, and 39% of untreated squamous carcinomas. With the possible exception of untreated squamous carcinomas, all these findings were comparable to ours. The fact that we found a higher number of positive cases overall may be attributed to several reasons. Our series is relatively small, and, however consistent the results seem to be, it is likely that a larger number of cases studied would also yield a higher percentage of negative ones. On the other hand, the method used by Riou et al.,[14] i.e., slot blot analysis of mRNA content, in spite of a very high sensitivity, has an inherent limitation that the authors have pointed out: The material analyzed by slot blotting is a homogenate of tissue, containing not only tumor cells but also a variable stromal and normal tissue component. If the latter is large enough, it may well dilute the content of target mRNA from the tumor (or colonies of positive cells within it) and thus produce a false-negative result. Three of our 10 positive tumors had only between 5% and 20% cells that were reactive for P-glycoprotein, and the reaction was weak in two of the three cases (Table I). It is likely that some or all of these samples would have produced a negative result if analyzed for mRNA, especially considering that all our specimens contained significant (and often predominant) portions of stroma or normal tissue. Both myometrium and isthmus in our normal control biopsy specimens, for instance, have been consistently negative for P-glycoprotein in this series, although representing the largest portion of tissue present on each preparation. All this may well explain the only significant discrepancy between our results and those reported by Riou et al.,[14] who found only 39% positive cases among their untreated squamous cervical carcinomas, whereas five of our six cases (83%) were positive. However, of our five positive cases, only one (20%) showed a strong (++) reaction, whereas the other four, with a weak reaction in the tumor cells and a significant proportion of nonreactive stromal and normal cervical tissue, could easily yield a false-negative result if analyzed for mRNA. In this context we have referred in previous articles[9, 12] to the relative advantages of immunohistochemistry for the study of P-glycoprotein expression in clinical tumor specimens. In addition to being cheaper and less complicated to perform than the sophisticated methods of molecular biology, it has the added advantage of preserving the histologic structure of the tissues studied. It thus allows researchers to discern which cells do express P-glycoprotein and whether these are tumor cells. On the other hand, it has the drawbacks of lower sensitivity and of being a purely qualitative method, not allowing quantitation of the results obtained.

On the basis of the current study it may be concluded that cervical carcinoma belongs to the category of tumors arising from organs with high intrinsic levels of P-glycoprotein, and these tumors also tend to be highly chemoresistant. It has been postulated that all these organs, which have in common excretory and detoxifying functions, overexpress P-glycoprotein as part of a wide array of defense mechanisms and that chemoresistance is only a byproduct of them.[1-3] Cervical adenocarcinoma, which originates on a glandular epithelium, would fit well into this model. Why the squamous epithelium of the cervix, which has no known detoxifying or excretory function, also expresses P-glycoprotein, giving rise to tumors with the multi-drug-resistance phenotype, is a mystery it shares with connective tissue, which, being equally nonspecific in function, gives rise to sarcomas that express high levels of P-glycoprotein.[15] It is, however, coincident with the clinical finding that cervical carcinoma tends to be minimally responsive to chemotherapy and that the few agents to which it responds best do not belong to the multi-drug-resistance type.[10] Indeed, in a prospective study conducted by the Gynecologic Oncology Group, it was concluded that the addition of vincristine (a multi-drug-resistance type), mitomycin C, and bleomycin to cisplatin in the treatment of advanced or recurrent cervical carcinoma was not superior to cisplatin alone.[16] In the light of this report, the astonishingly high response rates reported by Giaroli et al.[11] for neoadjuvant therapy with three preoperative courses of vincristine, bleomycin, and cisplatin may be attributed mainly to cisplatin and to a lesser degree to bleomycin and the multi-drug-resistance agent vincristine. Moreover, the single drug eliciting the highest response rate in all published series is cisplatin,[17] and it is well known from experimental studies that multi-drug-resistant tumor cells tend to retain their sensitivity to cisplatin because the resistance to this agent is probably mediated by other mechanisms, such as glutathione–*S*-transferase,[18] which are completely different from P-glycoprotein.

There are some clinical implications to be derived from our findings. In view of them, it would seem of little value to use chemotherapy of the multi-drug-resistance class for the treatment of cervical carcinoma. This is substantiated by previous clinical trials, as revised by Thigpen et al.,[17] where these agents elicited very low response rates when used singly. In addition, if we may extrapolate from the experience with other tumors derived from organs with high intrinsic levels of P-glycoprotein (kidney, liver, colon, etc.), even the use of agents not related to the multi-drug-resistance

phenomenon will probably never attain the effectiveness reached in chemosensitive tumors, such as mammary and ovarian carcinoma, which, of significance, express P-glycoprotein in a much lower proportion of cases before treatment.[9, 12, 19] A theoretic way out of this dilemma may be the circumvention of multidrug resistance with drugs inhibiting P-glycoprotein function. A number of membrane-active compounds, such as verapamil and trifluoperazine, are able to completely reverse multidrug resistance mediated by P-glycoprotein when used under experimental conditions.[20] The doses needed for this, however, far exceed the therapeutic dose tolerated in humans; this represents the major obstacle to their clinical use.

In conclusion, P-glycoprotein was demonstrated with immunohistochemistry techniques in most cervical carcinomas studied. It was also present on the epithelium of all normal cervical controls. P-Glycoprotein may thus play a significant role in the known resistance to chemotherapy of cervical carcinomas, although other mechanisms of resistance must be implicated.

A randomized trial of prostaglandin E_2 in a controlled-release vaginal pessary for cervical ripening at term

Frank R. Witter, MD, Laura E. Rocco, MS, and Timothy R.B. Johnson, MD
Baltimore, Maryland

OBJECTIVE: The purpose of this study was to determine if prostaglandin E_2 in a controlled-release vaginal pessary can produce cervical ripening at term.
STUDY DESIGN: This was a double-blind, randomized, placebo-controlled study conducted at a university center and involving 81 patients with 42 receiving active agent. Categoric data were analyzed by Pearson's χ^2 or logistic regression. Continuous variables were analyzed by analysis of variance and the F test.
RESULTS: Prostaglandin E_2 was significantly better than placebo at cervical ripening and at decreasing the time to rupture of membranes, the time to onset of labor, the need to give oxytocin, and the time to vaginal delivery. Multiparous women benefitted more than primiparous ones. The cesarean section rate decreased only for multiparous women. Uterine hyperstimulation occurred only with prostaglandin E_2 and after the onset of labor.
CONCLUSIONS: Prostaglandin E_2, when administered in a controlled-release vaginal pessary, is affective in producing cervical ripening at term. This agent should be used on inpatients who are under continuous monitoring and it should be removed at the onset of labor. (Am J Obstet Gynecol 1992;166:830-4.)

Key words: Pregnancy, cervical ripening, induction of labor, PGE_2, prostaglandin

Prostaglandin E_2 (PGE_2) has been suggested as an agent to ripen the unfavorable cervix for induction of labor at term. It has several properties that might make it a likely candidate for this task. It can relax the smooth muscle of the cervix[1] and induce an increase in the production of glycosaminoglycans by cervical fibroblasts.[2] The increased glycosaminoglycans may be involved in cervical softening unrelated to uterine contractions, and such softening and increased extendibility have been associated with exogenous PGE_2 application.[3]

Unfortunately, for its role as a cervical ripening agent, PGE_2 is also a uterotonic agent for the pregnant uterus and there are concerns about production of hyperstimulation with its use.[2] PGE_2, when applied in a gel intracervically, has been documented to produce cervical ripening and occasional hyperstimulation.[4] Because PGE_2 is rapidly metabolized in the tissues of origin and by the lungs and gastrointestinal tract, if it were possible to remove the exogenous PGE_2, hyperstimulation could be rapidly reversed. A readily removable solid intravaginal dosage form would be welcome. This report describes a blinded, placebo-controlled trial of a new controlled-release intravaginal PGE_2 pessary for preinduction cervical ripening at term.

Material and methods

This study was approved by our institutional review board for human trials and consisted of a randomized, blinded, placebo-controlled trial of an intravaginal PGE_2 pessary for cervical ripening. Change in cervical status before induction was assessed by the Bishop score, as described in Bishop's classic article.[5]

The pessary is made of a cross-linked polymer hydrogel that releases PGE_2 at a near-constant rate of approximately 1 mg/hr in vitro. The total reservoir contained in the pessary was 10 mg. It was supplied together with placebo pessaries in foil wrappers, which were kept at −20° C until immediately before use.

The patients were recruited from women to be delivered at our hospital who were to have labor induced at term and who fulfilled the eligibility criteria listed in Table I.

After giving informed consent, the patient underwent a 30-minute observation period in which a nonstress test was performed. If this test was reactive and the patient met all other criteria, she entered the study and was randomly assigned to receive either active or placebo pessary. At the time of pessary insertion, a Bishop score was obtained and the thawed pessary was inserted into the posterior fornix of the vagina with its long axis transverse to the long axis of the vagina. The patient was asked to remain recumbent for the first 2

Table I. Eligibility criteria

1. Informed consent
2. Singleton pregnancy of ≥37 weeks' gestation
3. Cephalic presentation
4. Nulliparous or multiparous with ≤3 previous viable infants
5. A medical or obstetric indication for induction
6. Bishop score of ≤4 on admission
7. Reactive fetal nonstress test
8. No previous uterine scars
9. No vaginal bleeding
10. Intact membranes or premature rupture of membranes for ≤4 hours at insertion of pessary
11. No fever
12. No allergy to prostaglandins
13. No history of asthma or glaucoma, except for childhood asthma without adult recurrences
14. No evidence of fetal distress
15. No evidence of spontaneous labor
16. No evidence of clinical hydramnios, confirmed by ultrasonography
17. No use of aspirin, nonsteroidal antiinflammatory drugs, or acetaminophen within 4 hours before insertion of pessary and any time thereafter
18. No underlying maternal cardiac lesion that might put patient at risk from potential hypotensive effects of PGE_2

hours after insertion and then was allowed to get up as needed. The pessary was to remain in situ for 12 hours, during which continuous electronic monitoring was used to observe uterine activity and fetal heart rate. Repeat Bishop scores were performed by the same individual if possible at 6 and 12 hours after insertion. If, for any reason, the pessary had to be removed before 12 hours after insertion, a repeat Bishop score was obtained at removal. All pessaries still in situ at the time of the 12-hour Bishop score were removed at that time. After removal of the pessary, any patient who was not in labor underwent induction of labor with oxytocin. Amniotomy was performed at the discretion of the attending physician.

Eighty-one patients entered the study. Thirty-nine received placebo and 42 received the active agent. Of the original 81 patients, 36 placebo and 41 active-agent patients could be evaluated for cervical ripening. To be evaluated for cervical ripening the patient must have been eligible for the study and have had at least one Bishop score after the initial one. Of the placebo patients who could not be evaluated, one never received a pessary when it was determined after randomization that she had a uterine scar and was ineligible, the second patient had insufficient data to analyze because she had a cesarean delivery at 7½ hours after insertion for worsening severe preeclampsia, and the third had ruptured membranes for >4 hours at pessary insertion and was ineligible. The active-agent patient who could not be evaluated was ineligible because she had onset of labor at pessary insertion.

In addition to cervical ripening, the labor parameters that were of interest included time to rupture of membranes, time to onset of labor, length of the first stage of labor, length of the second stage of labor, and the time to vaginal delivery. Labor was defined as uterine contractions occurring at least every 3 minutes and lasting at least 45 seconds or cervical dilatation of 5 cm with any contraction pattern. All times were measured from pessary insertion, with the exception of the first and second stages of labor. Thirty placebo patients and 39 active-agent patients could be evaluated for these

labor parameters. Of the placebo patients who could not be evaluated for labor parameters, two had delays from pessary removal to initiation of induction of labor, one failed to go into labor after an extended induction and had a primary cesarean section, and three underwent serial attempts at induction with overnight rests between oxytocin administrations. The two active-agent patients who could not be evaluated had serial attempts at induction with overnight rests between oxytocin administration.

Statistical analysis was done with the Statistical Analysis System.[6] Categoric data were analyzed by either Pearson's χ^2 or logistic regression. Continuous variables were analyzed by analysis of variance and the F test.

Results

Demographic data (Table II), obstetric history (Table III), initial Bishop score (Table III), and primary indication for induction (Table IV) did not differ between the placebo and active-agent groups. This balance was not disturbed when the patients were stratified into those evaluable for cervical ripening and those evaluable for labor parameters or when these evaluable groups were substratified into multiparous and primiparous patients.

The primary outcome variable for this study was cervical ripening. Successful treatment outcome was defined as a change in Bishop score of ≥3, a Bishop score of ≥6, or vaginal delivery within 12 hours of pessary insertion. Table V lists several possible ways to gauge success in cervical ripening for evaluable patients. The results were unchanged when primiparous women were considered separately. When multiparous women were analyzed, only treatment outcome and onset of labor within 12 hours remained statistically different between the placebo and active agent.

Timing for labor events for evaluable patients is presented in Table VI. When primiparous patients were analyzed separately, only the time to rupture of membranes and the time to onset of labor remained statis-

Time to vaginal delivery			
Mean ± SD	32.3 ± 9.92 (n = 20)	20.9 ± 12.90 (n = 30)	0.0093
Range	18-75	5.0-55.7	

**p* Values from analysis of variance F test.
†Three patients with pessary insertion after membrane rupture not included.

tically different. For primiparous patients, the mean time to vaginal delivery with placebo was 32.9 hours and with active agent was 27.0 hours (p = 0.1633, analysis of variance F test). When multiparous patients were analyzed separately, in addition to the significant differences seen in the overall group, the mean length of the second stage of labor was significantly shorter with the active agent, 0.4 versus 0.9 hour with placebo (p = 0.0411, analysis of variance F test). For multiparous patients, the mean time to vaginal delivery was 29.7 hours with placebo and 14.0 hours with the active agent (p = 0.0016, analysis of variance F test).

Data for method of membrane rupture, type of analgesia in labor, method of delivery, and occurrence of episiotomy are listed in Table VII for evaluable patients. No statistically significant differences appeared when primiparous women were analyzed separately. The cesarean rate for primiparous women was 33% in both placebo and active-agent groups. When the multiparous women were analyzed separately, a statistically significant difference appeared in cesarean section rate, 33% for placebo versus 7% for active agent (p = 0.0100, Pearson's χ^2 test).

Data on oxytocin administration are given in Table VIII for evaluable patients. The results were unchanged when primiparous patients were analyzed separately. When multiparous patients were analyzed separately, the amount of oxytocin administered was no longer statistically different between the placebo and active agent. This may have been due to the small sample size, because all of the multiparous patients in the placebo group (n = 6) required oxytocin averaging 7.2 U total, whereas only 20% (n = 3) of the multiparous patients in the active-agent group required oxytocin averging 2.4 U total.

Three patients receiving the active agent had uterine hyperstimulation. No patient who received placebo had

uterine hyperstimulation. Uterine hyperstimulation was defined as uterine contractions lasting ≥2 minutes or a contraction frequency of five or more in 10 minutes with evidence that the fetus was not tolerating this contraction pattern, as demonstrated by late decelerations, severe variable decelerations, or fetal bradycardia.

The incidence of hyperstimulation in patients receiving the active agent was 7% in this study. These episodes occurred between 1 hour and 8 hours 50 minutes after pessary insertion. All resolved rapidly after removal of the pessary, and no further therapy was required. All episodes of hyperstimulation occurred after the onset of labor.

Comment

The PGE_2 pessary, which released PGE_2 at a near-constant rate of approximately 1 mg/hr in vitro, tested in this study is effective in producing cervical ripening when compared with placebo. It has a distinct advantage over PGE_2 gel or suppositories in that it releases a small amount of PGE_2 over a prolonged period rather than the entire dose rapidly.

The active agent results in significantly more patients going into labor during its 12-hour administration period than placebo. These findings are observed for both primiparous and multiparous patients. When we look past cervical ripening to benefits from pessary use in the subsequent labor, we find that the active pessary shortens the time to rupture of membranes and to onset of labor. It also decreases the need to administer oxytocin.

Additional benefits achieved by multiparous women are a shortened second stage of labor, a shortened time to vaginal delivery, and a decreased cesarean section rate.

The primiparous women gained some additional benefits. The average total amount of oxytocin needed to be administered was cut almost in half, from 12.0 to 6.3 U. Twenty-five percent of the primiparous women given the active agent required no oxytocin, as opposed to all of those given placebo. Additionally, those patients receiving the active agent who also received oxytocin were more likely to require only augmentation (50% vs 8% with placebo). Thirty-eight percent of the primiparous women given the active agent went into labor during the 12-hour period of pessary insertion, whereas none of those patients on placebo did. The time from pessary insertion to vaginal delivery was not shortened by active agent (27.0 hours, range 7.2 to 55.7 hours, vs placebo 32.9 hours, range 18 to 53 hours). The failure to achieve statistical significance is probably due to the wide range of time taken to achieve vaginal delivery. This should not be surprising as Bishop[5] in reporting his scoring system cautioned against elective induction of primiparous patients, because, even in the presence of apparently favorable circumstances, the duration of labor is unpredictable.

Uterine contractions were frequently produced by the active pessary. Irregular contractions and frequent mild contractions compatible with the diagnosis of uterine irritability (not perceived as painful, ≤20 seconds' duration, every 1 to 2 minutes) were the most frequent patterns. Uterine hyperstimulation as defined previously had an incidence of 7% in this study among patients receiving PGE_2. Hyperstimulation resolved immediately on removal of the pessary and resulted in no emergency deliveries. The solid dosage form of the pessary allows for easy removal of the PGE_2 when compared with other dosage forms. All patients with hyperstimulation were multiparous women in labor at the time of the incident. Because of this risk of hyperstimulation that could occur at any time during the administration of the pessary, PGE_2 pessaries should be administered only to inpatients who are having continuous external electronic fetal monitoring and should be removed at the onset of labor as defined here.

The resolution of chronic pelvic pain after normal laparoscopy findings

Philip N. Baker, DM, and E. Malcolm Symonds, MD
Nottingham, England

Sixty patients with chronic pelvic pain were monitored after diagnostic laparoscopy had excluded obvious pelvic pathology. Six months after the procedure only two patients described their symptoms as unchanged or worse. Treatment should be limited to the minority of patients whose symptoms remain 6 months after laparoscopy. (Am J Obstet Gynecol 1992;166:835-6.)

Key words: Peritoneoscopy, abdominal pain

Chronic pelvic pain with no obvious pathologic cause is a common complaint in gynecology clinics and accounts for a large proportion of diagnostic laparoscopies. The findings on laparoscopy are grossly normal in ≤66% of cases.[1] A wide variety of causes have been postulated, including pelvic venous congestion in the majority of these women.

As to treatment of these women after normal laparoscopy findings, in a small prospective study Pearce et al.[2] found that nondirective psychologic counseling helped reduce pelvic pain, with a minority of the nontreatment control group being free from pain after 1 year. Our current management of these patients does not include such counseling; after normal laparoscopy findings, patients are discharged to their general practitioners. Our study was undertaken to assess whether this management is adequate.

Material and methods

Sixty premenopausal women with a median age of 29 years were recruited to the study after undergoing laparoscopies with normal findings. Seventy-five women with histories of chronic pelvic pain had initially had laparoscopies performed (by P.N.B. or E.M.S.). Fifteen patients were excluded on the basis of pathologic findings (8 cases of endometriosis, 5 pelvic adhesions, 1 appendicitis, and 1 ectopic pregnancy). All 60 women had histories of pelvic pain of ≥3 months' duration before the laparoscopy. The character of the pain varied, being described as unilateral by 27 (45%), bilateral by 12 (20%), and generalized by 21 (35%). Thirty-three women (55%) reported no relationship between their symptoms and their menstrual cycles, whereas 27 (45%) reported that their pain was cyclic in nature.

All 60 women were reassured at a postoperative ward round that no gynecological abnormalities had been seen and were asked to attend outpatient follow-up appointments 6 weeks and 6 months after their laparoscopies. Recall of patients who did not initially attend follow-up appointments was done by mail and telephone. No detailed counseling was given at the follow-up appointments; patients were merely questioned about their symptoms and given general advice regarding simple analgesia.

Results

All 60 patients attended the 6-week follow-up appointment. Thirteen (22%) said they were pain free, 24 (40%) said their pain had diminished, and 23 (38%) said their pain was unchanged or worse.

Fifty-seven (95%) patients attended the 6-month follow-up appointment, with 33 (58%) reporting that they were pain free and 22 (39%) reporting that their pain had diminished. All 13 women who were pain free 6 weeks after the laparoscopy remained pain free 6 months after the procedure. None of these 55 patients believed that the pain had inconvenienced their lives to a significant extent in the 8 weeks before the 6-month appointment, and only three had taken simple analgesics to alleviate their symptoms. Two (4%) of the 57 patients described their symptoms as unchanged or worse. Both patients had consistently described their pain as generalized and unrelated to their menstrual cycles.

Comment

As in previous studies,[1] no diagnosis was made in this study after laparoscopy in the majority of women initially seen with chronic pelvic pain. However, from a pragmatic standpoint the findings we have presented suggest that the diagnosis itself is of limited importance.

Our study could be criticized for incorporating only a minimal attempt to quantify the subjects' pain. Nevertheless, the clear conclusion drawn from these results is that after a laparoscopy with normal findings, release

of the patient to the general practitioner is appropriate. Whatever the etiology of the pelvic pain, the symptoms of most patients improved or resolved. A psychologic component has frequently been suggested in women with chronic pelvic pain in the absence of pathology; presumably the reassurance derived from the results of the laparoscopy at least contributed to the improvement in symptoms. It would have been interesting to have compared this group with a similar group of patients who had not had laparoscopy to determine whether the laparoscope is truly therapeutic.

These findings were thus at variance with those of Pearce et al.[2] We suggest that treatment (including conseling) should concentrate on the small minority of patients whose symptoms remain 6 months after laparoscopy.

Prostaglandin E_2 for induction of labor in patients with premature rupture of membranes at term

Deborah A. Ray, MD, and Thomas J. Garite, MD
Santa Clara and Orange, California

OBJECTIVE: A prospective study comparing three management schemes for patients at term with premature rupture of membranes was performed.
STUDY DESIGN: One hundred forty patients were randomized to one of three study groups: prostaglandin E_2, placebo, or oxytocin. Patients randomized to prostaglandin E_2 and placebo received vaginal suppositories containing 3 mg prostaglandin E_2 or glycerin only, respectively; suppositories were administered in a double-blind fashion, on one or two occasions, 6 hours apart. Oxytocin was given only if labor was not established after 12 hours or to augment inadequate labor. In patients randomized to oxytocin labor was induced with intravenous oxytocin. The time interval to delivery, delivery outcome, and complications were analyzed.
RESULTS: Patients receiving prostaglandin E_2 were more likely to be in labor after one suppository and to be delivered without the addition of oxytocin when compared with placebo. The time interval to delivery was shorter with prostaglandin E_2 and oxytocin induction versus placebo ("expectant management"). The incidence of maternal infection was lowest in patients with labor induced by prostaglandin E_2. Although the overall cesarean section rate was low, there was a trend toward a lower rate with prostaglandin E_2 induction. No adverse effects were observed with prostaglandin E_2.
CONCLUSION: Prostaglandin E_2 can be used successfully to induce labor after premature rupture of membranes at term with greater ease of administration when compared with oxytocin. (Am J Obstet Gynecol 1992;166:836-43.)

Key words: Premature rupture of membranes, induction, prostaglandin

Management of the term gestation with spontaneous rupture of membranes before the onset of labor remains one of the most frustrating problems encountered by the practicing obstetrician. Its common occurrence and the considerable confusion that exists regarding the most appropriate course of management contribute to the frustration. An aggressive approach involving prompt administration of oxytocin to induce labor has been advocated in the past in an effort to reduce the significantly increased maternal and neonatal morbidity and mortality associated with infection[1]; however, oxytocin induction of labor in such patients has proved to be associated with an unacceptably high rate of cesarean delivery.[2-5] The vast majority of these operative deliveries are reported to be due to failed induction or lack of progress. A prolonged in-

duction and labor with multiple pelvic examinations can result in intraamniotic infection, associated dysfunctional labor, cesarean section, and subsequent endometritis.[6, 7] The alternative, expectant management, has resulted in a cesarean section rate that is approximately half that noted with oxytocin-induced labor[2-5]; however, expectant management can result in significant delay before delivery. Evidence indicates that the rate of intrapartum fever increases with a latent period after rupture of membranes of >24 hours in term gestations. Perinatal mortality and neonatal infectious morbidity have been reported to increase as well after prolonged premature rupture of membranes.[8]

Prostaglandins have been used by a number of investigators to ripen the cervix and induce labor.[9] Intravaginal or intracervical prostaglandin E_2 (PGE_2) has been found to be efficacious in inducing labor at term,[10-17] with the majority of patients delivered without the aid of oxytocin, most within 24 hours. The success rate is dependent on dose of prostaglandin, location of administration, condition of the cervix at the onset of induction, and parity. The rates of cesarean section for failed induction have been low in these studies. Other reported advantages of the use of prostaglandin in comparison to oxytocin for labor induction include decreased blood loss at delivery, decreased use of analgesics in labor, a lower incidence of neonatal jaundice, and greater patient satisfaction. Patient side effects have been few and uterine hypertonus encountered infrequently.

Few reports of use of prostaglandins in patients with ruptured membranes have appeared in the literature.[18-22] These studies document successful induction of labor with various prostaglandin preparations. Several studies reported reduction in intravenous oxytocin, analgesia, and lowered cesarean section rates. This study was undertaken to compare the effectiveness of intravaginal PGE_2 for induction of term labor with oxytocin induction and expectant management in patients with spontaneous rupture of membranes before the onset of labor.

Material and methods

The study was performed at the University of California, Irvine Medical Center and Long Beach Memorial Medical Center. Patients, recruited from both the private and clinic obstetric services, gave their informed consent. This study was approved by the human subjects committees of both institutions. Eligible patients included those at term (>36 weeks) with spontaneous rupture of membranes who presented before the onset of labor. All patients had singleton pregnancies with vertex presentations and no evidence of intrauterine infection or fetal distress. Rupture of membranes was documented by sterile speculum examination with positive ferning and Nitrazine tests. A digital cervical examination was not carried out until labor or oxytocin augmentation began. The cervix was observed on the initial sterile speculum examination and patients with advanced dilatation (≥3 cm) were excluded. Uterine activity of two or more contractions per 10 minute intervals at presentation was considered evidence of labor and resulted in exclusion. Patients who met all of the above criteria were excluded only if they refused to participate.

Eligible patients were randomly assigned to one of three study groups: PGE_2, placebo, or oxytocin. The randomization was performed by selecting the study group next on a random list maintained by the pharmacy personnel. Each time a patient was enrolled, the pharmacy was contacted and the labor and delivery staff informed if the patient was to receive oxytocin or suppository (PGE_2 or placebo).

Patients randomized to the oxytocin group immediately received intravenous oxytocin. The protocol for oxytocin induction in effect at the time of the study called for initiation of oxytocin by infusion pump at 3 mU/min and incremental increases (1 mU/min every 20 minutes) until adequate uterine activity was achieved. The protocol was consistently applied at both institutions and for all study groups. Internal monitors were used whenever the uterine contraction information provided by the external tocodynamometer was thought to be inadequate, fetal distress was suspected, or progress in labor deemed to be slow. Adequate uterine activity was defined as three uterine contractions of at least 50 mm Hg in intensity per 10-minute intervals.

Patients randomized to the PGE_2 and placebo groups received a vaginal suppository. PGE_2 suppositories were prepared by thoroughly mixing 20 mg PGE_2 suppositories in a glycerin base and creating individual suppositories containing 3 mg PGE_2. Placebo suppositories contained only glycerin. The suppositories were indistinguishable and given in a double-blind fashion. The code was not broken until data evaluation was begun after completion of the study.

The vaginal suppositories were carefully placed in the posterior fornix with a sterile glove. Patients receiving suppositories were reevaluated in 6 hours. Patients without regular uterine contractions, defined as more than two perceived uterine contractions per 10-minute interval, received a second suppository, the content of which was the same as the first. After an additional 6 hours, the patients were evaluated again, and those without regular uterine contractions received intravenous oxytocin, as noted. No digital cervical examinations were performed until patients were considered to be in labor or oxytocin was begun. Oxytocin for augmentation was used in patients with inadequate labor patterns and failing progress. Internal pressure catheters were used frequently to assess uterine activity when progress of labor was deemed to be slow. Deci-

sions regarding the course of labor were made by the resident physicians and attending staff on the basis of standard obstetric practice. Failure to progress resulting in delivery by cesarean section included patients with prolonged latent phase (>18 hours) and lack of dilatation or descent in active phase (<1 cm in 2 to 3 hours). Chorioamnionitis was diagnosed if maternal temperature exceeded 38° C during labor without evidence of other sources of fever. Antibiotics were initiated when the diagnosis was made. Endometritis was diagnosed when maternal temperature exceeded 38° C on two occasions or 38.5° C on one occasion after the first 24 hours post partum when uterine tenderness was present and other sources of fever were excluded. Prophylactic antibiotics were used routinely at the time of cesarean section. Neonates were admitted to the neonatal intensive care unit to rule out sepsis when prolonged rupture of membranes (>24 hours) and maternal fever during labor were present. Maternal records were reviewed to assess the duration of ruptured membranes, need for oxytocin, highest dose of oxytocin, time interval from intervention (oxytocin induction or placement of first suppository) to delivery, mode of delivery, maternal side effects and infectious morbidity, fetal effects, and neonatal morbidity. Statistical analysis was applied using χ^2, Fisher exact, and Student *t* test where appropriate.

Results

One hundred forty-three patients were randomized. Three patients, two in the placebo and one in the PGE_2 group, were excluded because of noncompliance with the study protocol. No significant differences in mean maternal age, parity, or duration of rupture of membranes on admission, were found among the three groups (Table I). The number of patients requiring oxytocin for induction or augmentation was significantly less with PGE_2 compared with placebo. The mean highest dose of oxytocin administered did not differ among the three groups. Of patients receiving suppositories, 47.5% in the PGE_2 group versus 71.1% in the placebo group required a second suppository after 6 hours ($p = 0.02$). Thus 52.5% of patients with labor induced with PGE_2 were having regular uterine contractions within 6 hours of receiving a single dose. The mean time interval to delivery with PGE_2 induction (16.3 ± 9.4 hours) and oxytocin induction (13.9 ± 7.7 hours) was significantly less than with placebo (21.2 ± 9.9 hours, $p < 0.05$). The cumulative number of patients delivered at ≤12 and ≤18 hours was significantly greater with PGE_2 and oxytocin induction than with placebo ($p < 0.01$) (Fig. 1). Among patients delivered vaginally, the mean time interval to delivery was significantly less with PGE_2 induction (15.3 ± 8.7 hours) and oxytocin induction (12.8 ± 7.3 hours) than with placebo (19.4 ± 8.7 hours, $p < 0.05$). The incidence of maternal infection requiring antibiotic treatment, which includes chorioamnionitis and endometritis, was lowest with PGE_2 (Fig. 2). A trend toward a lower incidence of cesarean section and cesarean section for failure to progress was seen in the PGE_2 induction group; however, this did not reach statistical significance (Fig. 3). There were no apparent differences between the groups in the distribution of cesarean sections for failure to progress in latent phase versus active phase. However, the number of cesarean sections performed is too small to allow statistical analysis.

Maternal side effects were minimal. Three patients who received suppositories, one in the PGE_2 and two in the placebo group, complained of nausea with or without vomiting. Two patients in the placebo group required subcutaneous terbutaline for treatment of

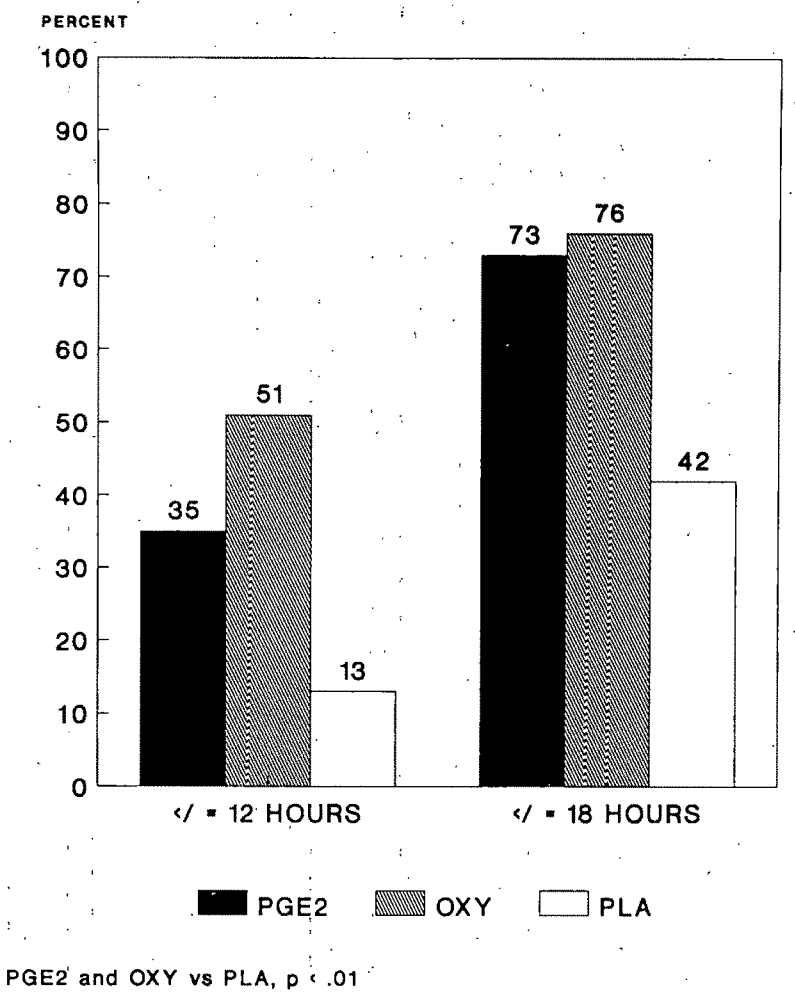

Fig. 1. Cumulative number of patients delivered.

prolonged decelerations of the fetal heart rate caused by hyperstimulation. There were no instances of hyperstimulation necessitating tocolytics in either the PGE_2 or the oxytocin group. One patient in the oxytocin group was delivered vaginally of an infant with a 5-minute Apgar score <7 after a prolonged deceleration. Seven neonates were admitted to the neonatal intensive care unit to rule out sepsis, two from the PGE_2 group, two from the oxytocin group, and three from the placebo group. In none of the neonates was sepsis documented and all had uneventful neonatal hospital stays.

The data for nulliparous patients and patients with at least one prior delivery (para ≥1) were analyzed separately (Tables II and III). All the trends previously noted in the overall population were evident for both the nulliparous and parous patients; however, with the smaller size of the groups not all comparisons reached statistical significance. The parous patients receiving PGE_2 for induction appeared to do particularly well. Only 21% of these patients required oxytocin and nearly 90% were delivered within 18 hours. This group had no cesarean sections, compared with four cesarean sections for failed progress among parous patients who received oxytocin induction.

When the results were stratified by hospital, there were no differences observed in the above noted trends.

Comment

The use of prostaglandins for cervical ripening and labor induction has been investigated in numerous randomized trials. Efficacy in both nulliparous and parous patients has been documented with few maternal side effects and good neonatal outcome.[10] Successful induction of labor and delivery without the addition of oxytocin has been reported in 60% to 90% of parous patients and 30% to 70% of nulliparous patients with intact membranes.[11-17] Few studies have considered patients with ruptured membranes. Hauth et al.[18] re-

ported on 100 patients who were not in labor 3 hours after spontaneous rupture of membranes at 38 to 41 weeks. In their comparison of oral PGE_2 with intravenous oxytocin, prostaglandin was successful in initiating active labor in 88% of patients. The interval from rupture to delivery was shorter and the cesarean section rate lower in patients induced with prostaglandin. MacLennan and Green[19] reported successful induction of term labor in patients with spontaneous rupture of membranes receiving intravaginal prostaglandin $F_2\alpha$. Prins et al.[20] treated 20 patients between 32 and 43 weeks with premature rupture of membranes and an unfavorable cervix with 2.5 mg of PGE_2 intravaginally, with a 55% incidence of spontaneous labor and no failed inductions. Two published studies have compared intravaginal PGE_2 and intravenous oxytocin. Ma-

gos et al.[21] reported equivalent outcomes when labor was stimulated with 3 mg PGE_2 pessaries and oxytocin after at least 4 hours of ruptured membranes in patients between 34 and 42 weeks. Ekman-Ordeberg et al.[22] randomized nulliparous term patients with premature rupture of membranes and unfavorable cervical status to receive either intravenous oxytocin or 4 mg PGE_2 administered intravaginally. One of 10 women receiving oxytocin was delivered vaginally within 24 hours versus six of 10 women after PGE_2 application.

This is the first report evaluating vaginally administered prostaglandin in patients with premature rupture of membranes at term in comparison with the two most commonly used methods of management, i.e., immediate induction with oxytocin and some period of expectant management before intervention with oxytocin. In the current study the placebo suppository group functions as an expectant management group,

as they received no mediation to initiate labor for 12 hours. This study included both nulliparous and parous patients of varying cervical status. We chose not to assess cervical Bishop score, as recent evidence has shown that infection rates increase when digital cervical examination is performed once membrane rupture has occurred.[6, 23] Additionally, we chose to assess the effect of PGE_2 in all patients to evaluate and compare its overall efficacy. Since patients with unfavorable cervical status are clearly the hardest in whom to successfully induce labor, it is possible that the differences might have been greater if only patients with unfavorable cervices had been included.

In this heterogeneous population, the use of PGE_2 significantly reduced the need for oxytocin and was highly successful in independently inducing labor, with nearly two thirds of patients not requiring oxytocin. Parous patients were even more likely to be successfully induced with prostaglandin alone (79%).

Although the latent period before the onset of labor in term patients with premature rupture of membranes may be prolonged, the duration of labor has been reported to be shorter with spontaneous labor after expectant management compared with oxytocin-induced labor.[4] Because the onset of labor is difficult to determine, we chose to evaluate the overall time interval from intervention (including onset of expectant management, i.e., placebo) to delivery. The current study demonstrates that both prostaglandin and oxytocin achieved equivalently shorter time intervals to successful vaginal delivery than did expectant management. We were unable to document any improvement in outcome with 12 hours of expectant management. This is in keeping with the results of a recent study comparing early versus delayed oxytocin induction of labor in 182 patients at term with spontaneous rupture of membranes in which no advantage to delay of induction was achieved with 24 hours of expectant management.[23]

The price that one pays for the shorter interval between rupture of membranes and delivery with oxytocin in most studies is a higher cesarean section rate. Compared with expectant management, oxytocin induction after premature rupture of membranes has been associated with rates of cesarean section ranging from 20% to 47%.[2-5, 22] The cesarean section rate in our population with oxytocin induction was relatively low compared with that in other reports (18% overall and 16% for failure to progress). However, the rate was even lower in the PGE_2 group (7.5%). Of the three types of management compared in the current study, the lowest cesarean section rate was achieved with vaginally administered PGE_2. Studies comparing oxytocin induction with expectant management have reported an increased incidence of maternal infections in patients with oxytocin induction. We also found a significantly increased rate of maternal infectious morbidity in the oxytocin group. This may be due at least in part to a tendency for more intervention, such as digital examinations and use of internal monitors in patients receiving oxytocin.

In this study the best combination of shortening the interval to delivery while keeping the cesarean section rate and maternal infection rate as low as possible was achieved with intravaginal PGE_2, followed by oxytocin when necessary.

The cavitational ultrasonic surgical aspirator for cytoreduction in advanced ovarian cancer

Peter G. Rose, MD
Worcester, Massachusetts

OBJECTIVE: The cavitational ultrasonic surgical aspirator is a newer surgical instrument that has been shown to be effective in tumor resection. The purpose of this study was to evaluate its usefulness for cytoreduction of advanced ovarian cancer.
STUDY DESIGN: Over a 24-month period patients with advanced ovarian cancer (stage IIIC and IV or bulky recurrent disease) were studied to determine the frequency of use of the cavitational ultrasonic surgical aspirator and the sites of tumor resection. The blood loss and operative time for patients who underwent surgery with the cavitational ultrasonic surgical aspirator were compared by Student *t* test with those of patients who did not undergo surgery with the cavitational ultrasonic surgical aspirator.
RESULTS: The cavitational ultrasonic surgical aspirator was utilized to effect optimal cytoreduction in 22 of 45 patients (48%). Of 52 sites of disease resected, 23 (44%) involved sites difficult to resect with standard operative techniques. These sites included the diaphragm, liver, spleen, and fixed retroperitoneal adenopathy. The cavitational ultrasonic surgical aspirator allowed resection from other sites, precluding procedures with potentially more morbidity. Of all 45 patients, 86% had cytoreduction to <2 cm and 44% to <0.5 cm. The blood loss and operative time were not different between cases in which the cavitational ultrasonic surgical aspirator was used and those in which it was not used.
CONCLUSION: The cavitational ultrasonic surgical aspirator appears to contribute to cytoreduction in patients with advanced ovarian cancer. (Am J Obstet Gynecol 1992;166:843-6.)

Key words: Ovarian cancer, cytoreduction, cavitational ultrasonic surgical aspirator

In advanced ovarian carcinoma, the volume of postoperative residual disease has been shown to significantly affect survival.[1] Furthermore, among the many factors that predict survival before chemotherapy initiation, this factor is the only one that is subject to modification. Aggressive surgical techniques have allowed the optimal debulking of postoperative residual disease in the majority of patients with advanced ovarian carcinoma.[2-4] Wharton and Herson[5] demonstrated that the survival of patients who required extensive surgical procedures was equal to that in those with easier cytoreduction. Although optimal debulking was originally defined as residual disease measuring 1.5 to 2 cm in greatest diameter, achieving even smaller residual disease appears to be beneficial.[1, 4]

The frequency of optimal cytoreduction varies in the literature and is a reflection of the aggressiveness of the surgical service. In addition to traditional surgical techniques, three newer instruments have been reported to be effective. These include the cavitational ultrasonic surgical aspirator,[6-8] the carbon dioxide laser,[9] and the argon beam coagulator.[10] The cavitational

ultrasonic surgical aspirator has been reported effective in debulking tumor from the diaphragm,[6, 7] spleen,[6] liver,[8] and intestine[6, 8] without injury to these organs. It may offer an advantage over the other two methods because it selectively spares connective tissue and blood vessels. This article reports the frequency with which the cavitational ultrasonic surgical aspirator was used during cytoreductive surgery for ovarian carcinoma and its effectiveness in contributing to the cytoreductive effort.

Material and methods

All patients with advanced ovarian carcinoma (stage IIIC or IV or bulky recurrent disease) who were operated on for the purpose of cytoreduction at The University of Massachusetts Medical Center during a 24-month period, from Aug. 1, 1988, to Aug. 1, 1990, were included. Patients with ovarian cancer who underwent exploration for purposes other than cytoreduction, including second-look laparotomy and intestinal obstruction, were excluded.

In all cases the surgical procedure consisted of abdominal exploration and resection of the primary tumor and metastatic deposits by standard operative technique. In each case the cavitational ultrasonic surgical aspirator was available and was used at the discretion of the surgeon if cytoreduction was not accomplished by standard operative techniques or if the cavitational ultrasonic surgical aspirator could be used with decreased morbidity. A cavitational ultrasonic surgical aspirator system 100 or 200 Macro-Dissector (Valleylab, Boulder, Colo.) with a frequency of 23,000 Hz was used to fragment and resect tumor. The amplitude of vibration controls the excursion of the instrument tip and the depth of tissue disruption. The amplitude setting most commonly used for tumor resection was 0.7 to 0.8 (210 to 240 μm). When the liver and spleen were resected, the amplitude was set at 0.4 to 0.5 (120 to 150 μm). The sites of tumor, operating time, blood loss, and postoperative residual disease were recorded. Statistical analysis was performed with a Student t test on Minitab Software (Minitab Inc., State College, Pa.).

Results

Forty-five patients with advanced ovarian disease including stage IIIC (n = 24), IV (n = 13), and recurrent disease >2 cm (n = 8) underwent cytoreductive surgery. The cavitational ultrasonic surgical aspirator was used in 22 (48%) (10 of 24 with stage IIIC, 9 of 13 with stage IV, and 3 of 8 with recurrent disease). The sites of disease that were resected with the cavitational ultrasonic surgical aspirator and the frequency with which these sites were resected are listed in Table I. Thirty-nine of the 45 patients (86%) had cytoreduction to <2 cm and 20 (48%) to <0.5 cm. The site of bulky residual disease was extraperitoneal in two of the six patients without optimal cytoreduction (supraclavicular node, n = 1, and lung, n = 1).

The diaphragm was the disease site where the cavitational ultrasonic surgical aspirator was most frequently used. Preresection tumor measurements varied from 5 × 5 × 5 to 5 × 8 × 10 cm. In the most advanced cases the liver was adherent to the diaphragm with tumor. In these cases the tumor between the liver and diaphragm was bluntly fractured, the liver was mobilized by transection of the falciform ligament, and the cavitational ultrasonic surgical aspirator was used to resect tumor from both the diaphragm and liver peritoneum. No pneumothoraces were demonstrated on postoperative chest radiographs.

Disease involving the liver parenchyma was resected in six patients. In five of the six the tumor was adequately cytoreduced. One patient, 25 years old, had multiple liver metastases measuring 8 cm in diameter, and only partial resection was accomplished. In this case the largest residual tumor measured 3 cm in diameter on a postoperative computed tomographic scan.

Six patients had bulky disease resected with the cavitational ultrasonic surgical aspirator that involved either the splenic hilum or the capsule. In one of these patients a splenic capsule laceration occurred because of operative retraction. This was controlled with conservative hemostatic techniques and observed without problems. In five cases tumor involving the gastrosplenic ligament was removed. During this same time period two patients underwent splenectomy by the gynecologic oncology service for cytoreduction.

The cavitational ultrasonic surgical aspirator was used for effective cytoreduction in the colon in 10 patients. This avoided additional intestinal resection. However, five of the 22 patients undergoing cavitational ultrasonic surgical aspirator did require intestinal resection. In two cases, because of previous pelvic or

Table II. Comparison of operative time and estimated blood loss

	Cavitational ultrasonic surgical aspirator (n = 22)	*No cavitational ultrasonic surgical aspirator (n = 23)*	*p Value*
Operative time (min, mean ± SD)	246 ± 89	266 ± 132	$p = 0.56$
Estimated blood loss (ml, mean ± SD)	1018 ± 803	897 ± 692	$p = 0.59$

abdominal radiation, a colostomy was performed. Eight of the 23 patients in whom the cavitational ultrasonic surgical aspirator was not used required intestinal resection to complete cytoreduction. Four of these patients required colostomy or ileostomy.

Four patients had resection of bladder tumor with the cavitational ultrasonic surgical aspirator. In two additional patients partial bladder resection was performed because tumor involving the bladder was adherent to the anterior abdominal wall.

There was no difference in the operative time or blood loss between those patients who underwent cavitational ultrasonic surgical aspirator resection and those treated by standard surgical techniques (Table II).

Comment

The cavitational ultrasonic surgical aspirator is a relatively new surgical instrument that uses ultrasonic vibration to fracture tissue that is high in water content. The instrument can be used to destroy tumor tissue because of its high water content and relative lack of collagen. It selectively spares connective tissue and prevents injury to bowel, blood vessels, or the peritoneum of the pelvis or diaphragm. The amplitude of vibration can be adjusted to suit the precision or rate of tissue destruction desired. Where there are smaller amounts of connective tissue, such as the liver or spleen, the amplitude of vibration must be decreased to avoid resection of normal organ parenchyma.

The goal of surgery in advanced and recurrent ovarian cancer is to minimize the amount of postoperative residual tumor. Certain tissues, including the liver and diaphragm, and cases of fixed retroperitoneal adenopathy are difficult to cytoreduce by standard operative techniques. Other sites of bulky disease, including the spleen, bladder, and small and large intestine, can be resected. However, each of these procedures is associated with its own morbidity. In the current study the cavitational ultrasonic surgical aspirator was found to be effective in contributing to cytoreduction in 48% of patients with advanced ovarian cancer. Of the 52 sites of disease resected, 23 (44%) involved either the diaphragm, liver, spleen, or fixed adenopathy. In the remaining 29 sites, the cavitational ultrasonic surgical aspirator precluded the need for more extensive surgery.

The frequency with which patients in this series had cytoreduction to <2 cm (86%) compares favorably with that of other reports in the literature.[2-4] Furthermore, 44% of patients had cytoreduction to <0.5 cm. On the basis of prior reports, such minimal residual disease should confer improved survival.[1, 4] However, longer follow-up will be required to determine the effect of such complete cytoreduction on the survival of our patient population.

One of the benefits of the cavitational ultrasonic surgical aspirator over laser techniques is that it selectively avoids injury to tissues with high connective tissue content. This has allowed it to be used safely on the intestine without reported injury.[6, 8, 11] However, in rare cases certain desmoplastic tumors with high collagen content may be difficult to resect.[8] Such fibrotic tissues can be optimally resected in combination with either standard operating techniques,[8] continued cavitational ultrasonic surgical aspirator resection,[12] or laser techniques.[9] Only one patient in the current series had such a desmoplastic tumor. This patient had optimal cytoreduction by a combination of the cavitational ultrasonic surgical aspirator with standard techniques.

One of the criticisms of the cavitational ultrasonic surgical aspirator has been that the dissection is tedious and operating time increased.[8, 11] Adelson et al.[6] reported its use in 10 patients with intraabdominal tumors with a mean operating time of 49 minutes. However, operating time may be offset if extensive dissection and reconstruction required by standard techniques can be avoided. For example, if the cavitational ultrasonic surgical aspirator is used to resect tumor involving the sigmoid colon, this should be compared with the time to resect the sigmoid colon and the time to complete either intestinal reanastomosis or diversion. In our study the operating room time in those patients in whom the cavitational ultrasonic surgical aspirator was used was slightly shorter than but not statistically different from that in patients in whom it was not used.

Few studies have examined operative blood loss during cavitational ultrasonic surgical aspirator surgery. Deppe et al.,[8] reporting their results in 11 women with ovarian cancer, noted an apparent decrease in blood loss.[8] In our study the mean operative blood loss was 1018 ml and was not statistically different from that in patients in whom the cavitational ultrasonic surgical aspirator was not used.

In this study the cavitational ultrasonic surgical aspirator appeared to contribute to the cytoreductive effort, because it was used by the surgeon in nearly half of the cases after standard operative techniques already had been used for cytoreduction. However, the reader should be aware that proof of the cavitational ultrasonic surgical aspirator's efficacy would require a randomized study where patients would by chance undergo completion of their cytoreduction with the cavitational ultrasonic surgical aspirator or be left with bulkier residual disease. Additionally, subsequent long-term follow-up is needed to prove a survival benefit to those patients who underwent cavitational ultrasonic surgical aspirator–assisted cytoreduction. Because cytoreductive surgery, although based on retrospective nonrandomized analyses, is so basic to our current management of ovarian cancer, such a study is unlikely to be completed.

UNIVERSITY OF MICHIGAN MEDICAL CENTER

The Department of Obstetrics and Gynecology at the University of Michigan Medical Center is seeking three Board certified or active candidate Obstetrician/Gynecologists to serve as tenure track faculty members in the Division of Maternal-Fetal Medicine. Responsibilities will include the teaching of house officers and medical students, conducting clinical and/or basic research, and patient care. Desired areas of interest should include ultrasound, prenatal diagnosis, fetal therapy and placental studies. Research experience also desired. Salary and academic rank will be commensurate with the candidates' training and experience. Please direct inquiries and curriculum vita to:

Robert H. Hayashi, M.D.
J. Robert Willson Professor of Obstetrics
Director, Maternal-Fetal Medicine
Women's Hospital L3208-0264
1500 East Medical Center Drive
Ann Arbor, Michigan 48109-0264

The University of Michigan is an Equal Opportunity/Affirmative Action Employer. Codes 21,23,28.

OBSTETRICIAN GYNECOLOGIST

UNIVERSITY OF CONNECTICUT

Board certified or Board eligible general obstetrician-gynecologist for academically oriented University faculty position. Excellent opportunity to teach residents and medical students, care for patients, become involved in academic research initiatives and develop administrative skills.

Does oxytocin augmentation increase perinatal risk in primigravid labor?

David J. Cahill, MB, Peter C. Boylan, MAO, and Colm O'Herlihy, MD
Dublin, Ireland

To assess the influence of high-dose oxytocin augmentation of spontaneous labor, a consecutive series of 30,874 primigravid term deliveries were analyzed for adverse perinatal outcome. In spite of a longer mean duration of labor, the frequencies of asphyxial perinatal death, neonatal seizures, and abnormal neonatal neurologic behavior were not significantly increased in 14,119 (45%) oxytocin-treated patients. There was no case of uterine rupture in any primigravid labor during the study. These results from 13 years of clinical practice provide reassurance about maternal and fetal safety if oxytocin is used as part of a protocol of active management to correct dystocia when spontaneous primigravid labor with vertex presentation fails to progress. (Am J Obstet Gynecol 1992;166:847-50.)

Key words: High-dose oxytocin augmentation, active management of labor, adverse perinatal outcome

It has been suggested that dystocia is the primary cause of the rising international rates of cesarean section in first labors.[1-3] Early diagnosis and correction of dystocia in primigravid women have been shown to effectively counter this rising trend in both Europe[4-6] and North America.[7,8] High-dose oxytocin administration forms an essential part of programs of active augmentation by improving uterine contractility and preventing prolonged labor.[9] It has, however, been suggested that the price to be paid for more efficient uterine activity may be an increased risk of perinatal asphyxia resulting from myometrial hyperstimulation.[10-12]

At the National Maternity Hospital in Dublin, a standard regimen of high-dose (6 to 40 mU/min) intravenous oxytocin therapy has been used in slowly progressing primigravid labor for >20 years. The fact that no case of uterine rupture has resulted from this regimen underlines its maternal safety in relation to augmented primigravid labor.[13] To reassess the influence of oxytocin on the incidence of perinatal asphyxia, we analyzed our experience with oxytocin augmentation in spontaneous primigravid labor at term. Only primigravid women were included because of the well-documented risks of uterine hyperstimulation in multigravid women.[14,15]

From the Department of Obstetrics and Gynaecology, University College Dublin, National Maternity Hospital.
Received for publication September 10, 1990; revised August 6, 1991; accepted August 27, 1991.

6/1/33428

Methods

An analysis of 35,726 consecutive primigravid deliveries was undertaken at the National Maternity Hospital during the period January 1976 to December 1988. Excluded from analysis were multiple pregnancies (n = 330), elective (prelabor) cesarean sections (n = 494), labor induced by medical or surgical methods (n = 1762), breech and other malpresentations (n = 751), and deliveries <37 completed weeks' gestation (n = 1515). All births occurred in our hospital. Data on the augmentation of labor, perinatal deaths, and abnormal neurologic behavior were collected prospectively during the period and were collated in the hospital's Annual Clinical Reports (1976 through 1988).[13] Individual patient records were reviewed where appropriate.

Postmortem examinations were carried out on all term perinatal deaths during the 13 years. Asphyxial perinatal death was defined according to autopsy findings in infants who died during labor or in the first week of life but excluded deaths associated with cord prolapse. Abnormal neurologic behavior was defined as a syndrome of abnormal tone and primitive reflexes with evidence of cerebral irritation manifested by irritability or motor seizures[16]; asphyxial seizures were diagnosed in the presence of any myoclonic, multifocal clonic, generalized tonic, or focal clonic activity within the first week of life in the absence of a metabolic or infective cause.[17]

Primigravid labor was managed along uniform and clearly defined guidelines throughout the period studied.[15] Diagnosis of labor was based on the presence of uterine contractions supported by spontaneous rupture

Table I. Adverse perinatal outcome related to oxytocin augmentation in 30,874 consecutive spontaneous primigravid labors

	Oxytocin augmentation (n = 14,119)	*No oxytocin (n = 16,755)*	*p Value**
Asphyxial death	24 (1.7/1000)	28 (1.7/1000)	0.94, NS
Asphyxial seizures	31 (2.2/1000)	21 (1.3/1000)	0.06, NS
Neurologic abnormality without seizures	22 (1.7/1000)	20 (1.3/1000)	0.48, NS

*χ^2 Test.

of the membranes or passage of blood-stained mucus vaginally and effacement or dilatation of the cervix on pelvic examination. Oxytocin augmentation was defined as stimulation after the spontaneous onset of labor and was initiated in primigravid women if, within 3 hours of admission, cervical dilatation had not progressed by 1 cm/hr. Oxytocin was administered by infusion of 10 U/L of 5% dextrose solution, commencing at 6 mU/min and increasing incrementally every 15 minutes to a maximum rate of 40 mU/min. Oxytocin usage was confined to primigravid women with singleton pregnancies at term with vertex presentations and with no evidence of fetal distress; if a fetal heart rate abnormality or meconium-stained amniotic fluid was detected, oxytocin was withheld until normal fetal pH status was established by scalp blood sampling. Fetal surveillance was generally performed by intermittent auscultation.[18] Continuous electronic fetal monitoring was carried out on a selective basis when indicated by abnormal fetal heart rate on auscultation, meconium-stained or absent amniotic fluid after amniotomy, or preexisting conditions such as fetal growth retardation or antepartum hemorrhage.

At birth, asphyxial morbidity was assessed by (1) Apgar scores <7 at 1 minute, (2) when performed, cord venous pH values <7.2, and (3) pediatric follow-up of all babies showing abnormal neurologic behavior, with or without seizure activity, during the first week of life; cord pH was routinely determined in infants requiring resuscitation at birth only during the last 5 years of the study period, and so the numbers for analysis of this parameter are smaller.

Statistical analysis was performed with the Student *t*, χ^2, and Fisher exact tests, of significance at the 5% level.

Results

The overall hospital perinatal mortality rate (including stillbirths and first-week neonatal deaths after 28 weeks' gestation) among primigravid women during the period was 14.6 per 1000 (10.1/1000 when lethal malformations were excluded). The overall primigravid incidences of asphyxial neonatal seizures and abnormal neonatal neurologic results were 2.0 per 1000 and 1.4 per 1000, respectively. A total of 35,726 primigravid women were delivered during the 13 years studied, 930 (2.6%) of whom labored for ≥12 hours.

After 4852 exclusions were made on the basis of the criteria already mentioned, the study group of 30,874 primigravid women remained who entered labor spontaneously at term with singleton live pregnancies and vertex presentations. Of these, 14,119 (45%) received oxytocin to augment labor that was progressing slowly, as defined by a rate of cervical dilatation of <1 cm/hr. The incidence of intrapartum cesarean section was 3.1%; the incidence of instrumental delivery was 13.9%. There was no case of uterine rupture among the patients studied.

In total, there were 52 (0.17%) asphyxial perinatal deaths, 23 stillbirths, and 29 neonatal deaths. Ninety-four (0.3%) infants showed abnormal neurologic behavior; 52 (0.16%) of them had seizures associated with evidence of asphyxia. Oxtyocin augmentation did not influence the incidence of these complications (Table I).

Among those primigravid women with an adverse perinatal outcome, patients with oxytocin augmentation did not differ significantly in terms of maternal or gestational age from those not given oxytocin (Table II). Not surprisingly, however, mean duration of labor was significantly longer in association with augmentation and mean birth weight was higher among the oxytocin-treated patients with adverse outcomes. The duration of augmentation was similar, regardless of the type of adverse outcome, with mean total administered oxytocin dosages of 8 U.

Cord venous pH estimations were performed in 80 (65%) of 123 live born infants who had an adverse outcome (Table III). In 57 (71%) cases the value was low (pH <7.20). The proportions of infants with low cord pH values were not different between the augmented and nonaugmented groups. One hundred four (85%) infants had 1-minute Apgar scores <7; a greater proprtion (54/59, 92% vs 50/64, 78%) of these low scores associated with adverse outcomes followed nonaugmented labor.

Comment

The purpose of this study was to assess whether adverse perinatal outcome, specifically asphyxial perinatal death and abnormal neonatal neurologic behavior, with or without early seizures, was more common after the use of oxytocin to augment spontaneous labor in sin-

gleton pregnancies at term with cephalic presentations. These results show that high-dose oxytocin acceleration does not increase fetal risk as measured by these adverse outcome variables. The protocol of labor management and fetal surveillance did not alter throughout the study period.

Although this investigation is retrospective and the statistical power of analyzing the small abnormal subgroups is somewhat reduced, nevertheless untreated patients who experienced bad outcomes did not differ from the oxytocin-treated group in any respect, apart from their more efficient uterine activity, shorter labors, and apparently smaller babies (birth weight being significantly different only in cases of perinatal death). Therefore our results are reassuring when viewed in association with evidence that cord arterial pH and P_{CO_2} values are unaffected by high-dose oxytocin stimulation.[19] In addition, we can confirm that oxytocin is completely safe in primigravid women in terms of the risk of uterine rupture.

The duration of primigravid labor at term is directly correlated with birth weight,[20] and our finding in complicated pregnancies that the duration of labors augmented with oxytocin was longer merely reflects the restriction of oxytocin usage to primigravid women in whom the progress of cervical dilatation was delayed. Indeed, further prolongation of such labors, were oxytocin withheld, might have been expected to increase, rather than reduce, the likelihood of fetal hypoxia.[21] Given that oxytocin-stimulated labors lasted longer and were thus potentially more hypoxic, the absence of a preponderance of perinatal complications in this group

further emphasizes the safety of the active management protocol used. Slow progress of cervical dilatation during the first stage of labor is the most reliable clinical indication of dystocia in primigravid women. A consequence of the avoidance or inadequate administration of oxytocin in these circumstances is an inevitable acceptance of a greater incidence of cesarean delivery in such patients. Our data suggest that such an approach cannot be justified on the grounds of potentially increased fetal jeopardy in augmented labors. When suboptimal dosages of oxytocin are used, cervical dilatation may be stimulated in some subjects, but cesarean delivery rates up to sixfold higher have resulted from uncorrected dystocia, often after labors lasting considerably longer than our 12-hour maximum.[22]

Our analysis of a very large number of first labors managed with a standard intrapartum regimen includes an asphyxial mortality rate of <2 per 1000 among nulliparous women during the period studied. By reflecting the practice of a large obstetric hospital over many years, rather than a restricted research context, it serves to emphasize that oxytocin used in clearly defined clinical circumstances in primigravid labor does not increase fetal hazards but instead acts as the keystone for the early correction of dystocia and helps to maintain a low incidence of primary cesarean delivery without additional fetal jeopardy.

The frequency of breech presentation by gestational age at birth: A large population-based study

Durlin E. Hickok, MD, MPH,[a, b] Diane C. Gordon, MS, MPH,[b] John A. Milberg, MPH,[b] Michelle A. Williams, ScD,[a, b] and Janet R. Daling, PhD[b]

Seattle, Washington

From a study of birth records, breech presentation at delivery for each gestational age was found to be less frequent as compared with other reports about antenatal ultrasonographic examination. Selection bias or the effect of labor may account for the observed difference. (AM J OBSTET GYNECOL 1992;166:851-2.)

Key words: Breech presentation, gestational age, ultrasonography

Breech delivery has always been a subject of great interest, in part because of the associated increased perinatal mortality and morbidity. Although the greatest cause of the adverse outcome associated with breech delivery is low birth weight, congenital malformations also contribute to the increased morbidity and mortality risk. Recent reports concerning the frequency of breech presentation by gestational age have been derived by antenatal ultrasonographic examination.[1, 2] We undertook this study to examine this relationship with a large, population-based data set of birth records.

Material and methods

We examined computerized birth certificate tapes for 136,199 births occurring during 1986 and 1987 in Washington State. For the purpose of this study, we excluded multiple births because they are associated with an excess abnormal fetal presentation. To most accurately describe the overall frequency of breech presentation by gestational age, we did not exclude cases with fetal or uterine anomalies. Information was missing in 9028 cases (7.0%), leaving 127,171 births for analysis. Accuracy of information in the Washington State Birth Record is excellent, with an error rate of <4% as determined by comparison with hospital records.

Results

The frequency of breech presentation was highest at the earliest gestational ages (Table I). In Washington State 20.6% of deliveries at 25 to 26 weeks were complicated by breech presentation. The frequency of breech presentation dropped rapidly after 28 to 30 weeks to a nadir of 1.7% after 40 weeks. After comparison with that in other series as determined by ultrasonography, the prevalence of breech presentation in Washington State was less for every gestational age category.

Comment

Although gestational age is the single greatest determinant of fetal presentation, other causes have been ascribed, including uterine relaxation as a secondary effect of parity, hydramnios, uterine anomalies (including fibroids), and abnormal placental implantation.

Scheer and Nubar[1] reviewed ultrasonography findings on 2276 patients in the second half of pregnancy at the Boston Hospital for Women for a 12-month period during 1974 and 1975. There were multiple indications for most examinations; rarely was ultrasonography performed only for ascertainment of fetal lie. Their findings were similar to those of Hill,[2] who reviewed 4024 ultrasonographic examinations performed in the second and third trimesters at the Mayo Clinic during 1982 and 1983. Information was used from the first visit only, and cases with twins, congenital anomalies, polyhydramnios, oligohydramnios, and uterine anomalies were excluded.

Our study differs in several important respects. The frequencies presented are derived from population-based data and are less subject to potential selection biases than hospital-based studies of patients seen at referral centers. Although the data base used for this study was large, it still may not be applicable to other populations with differing demographic and reproductive characteristics. Seven percent of the birth records had missing information for presentation at delivery; however, unless the majority of the missing cases were actually breech, the frequencies would remain relatively unchanged.

Our finding of less frequent breech presentation at each gestational age varies somewhat from the findings of other investigators. It is especially evident from 29 to 32 weeks, where a difference of >5% is found between this study and others. We believe that our data represent a more accurate description of this relationship, perhaps because information from delivery rather than from antenatal ultrasonography was used. It is also possible that labor may have an effect on the final presentation of the fetus before birth. Alternatively, selection bias may account for the higher frequency of breech presentation at all gestational ages, as reported by other authors.

Ovarian carcinoma of low malignant potential, infertility, and induction of ovulation—Is there a link?

Gary L. Goldberg, MD, and Carolyn D. Runowicz, MD
Bronx, New York

Three cases of ovarian carcinoma of low malignant potential associated with infertility and ovulation induction are reported. The natural history of ovarian epithelial tumors is possibly being interrupted with earlier intervention and diagnosis in patients who may have presented 10 to 15 years later with disseminated ovarian carcinoma. (AM J OBSTET GYNECOL 1992;166:853-4.)

Key words: Ovarian carcinoma, infertility, ovulation induction

There appears to be an increasing incidence of borderline tumors of the ovary in young women. We observed an association of these ovarian tumors with a history of infertility and subsequent induction of ovulation. Three patients <35 years old presenting to this institution with the diagnosis of ovarian carcinoma of low malignant potential had histories of infertility, infertility management including laparoscopy, induction of ovulation with menotropins (Pergonal, Serono Laboratories, Randolph, Mass.), and serial ultrasonography to evaluate follicular size, and pregnancy.

Fischel and Jackson[1] postulated the potential risk of ovarian, endometrial, and breast carcinoma from excessive ovarian stimulation. There have been reports in the British and European literature of seven cases of ovarian carcinoma associated with ovulation induction.[2] These cases were all associated with clomiphene citrate induction of ovulation. Six of these seven patients received clomiphene for >1 year and one received clomiphene plus Pergonal.

To our knowledge there has not been a report of ovarian carcinoma associated with induction of ovulation in the American literature.

All the patients in our series received Pergonal therapy for induction of ovulation, and serous ovarian tumors of low malignant potential developed in all.

Case reports

Case 1. A 32-year-old woman with a long history of primary infertility was enrolled in the in vitro fertilization program and received two cycles of Pergonal, resulting in a successful intrauterine pregnancy with the second cycle. She underwent cesarean section and was noted to have excrescences on the right ovary. Biopsies revealed a serous adenocarcinoma of low malignant potential. Elective surgical staging and right salpingo-oophorectomy confirmed the diagnosis.

Case 2. A 25-year-old woman with a 2-year history of primary infertility was accepted into the in vitro fertilization program and had three cycles of induction of ovulation with Pergonal. A successful intrauterine pregnancy resulted from the third cycle. She underwent follow-up with regular pelvic ultrasonography. She was found to have a 10 cm complex left ovarian mass at 19 weeks' gestation. She underwent exploratory laparotomy and a left salpingo-oophorectomy. Histopathologic examination revealed a serous adenocarcinoma of low malignant potential. She experienced no problems after operation, and the pregnancy progressed to term. She had a cesarean section and complete surgical staging.

Case 3. A 28-year-old woman with primary infertility who underwent induction of ovulation with Pergonal, resulting in an intrauterine pregnancy after two cycles of therapy, was found to have a right adnexal mass and underwent follow-up with serial sonograms. She presented with an acute abdomen at 21 weeks' gestation, presumably from torsion of an ovarian cyst. She underwent exploratory laparotomy and ovarian cystectomy. The final pathologic examination revealed a serous adenocarcinoma of low malignant potential. After delivery of a viable infant, she had elective surgical staging.

Comment

The incidence of ovarian tumors of low malignant potential may not actually be increasing, but the diagnosis is being made earlier in this select group of patients who are under intense medical surveillance. They have frequent sonograms and undergo laparoscopy and a high percentage have cesarean section. It may be coincidental that ovarian carcinoma developed in this subgroup after induction of ovulation. If these cases had been undetected or undiagnosed, the women may have presented with late-stage ovarian carcinoma

10 or 15 years later. We may have interrupted the natural history of the disease with earlier intervention and diagnosis.

These case reports are clinical and not scientific data. However, the clinical observation is important and one that we believe requires evaluation and follow-up. It might be prudent to set up a national registry for patients <35 years old with ovarian carcinoma. If this confirms our observation and the common denominator is infertility with subsequent ovulation induction, further study regarding this issue appears warranted. This may have an effect not only on the management of patients with infertility but also in the earlier diagnosis of patients with ovarian carcinoma.

Maternal and fetal cardiovascular responses to strenuous bicycle exercise

Marieke B. van Doorn, MD,[a] Fred K. Lotgering, MD, PhD,[a] Piet C. Struijk, BSc,[a] Jan Pool, MD, PhD,[b] and Henk C.S. Wallenburg, MD, PhD[a]

Rotterdam, The Netherlands

In a longitudinal study we investigated some cardiovascular responses to strenuous bicycle exercise in 33 healthy women during pregnancy and the postpartum period. The exercise electrocardiogram demonstrated depression of the ST segment in 12% of women in the absence of clinical signs of ischemia, and the incidence of these changes was unaffected by pregnancy. In spite of slightly different blood pressures at rest during the first and second trimesters of pregnancy, the blood pressure response to exercise at approximately 75% $\dot{V}O_2$max was virtually unaffected by pregnancy. After a maximal bicycle test, the fetal heart rate was increased by an average of 4 beats/min, without a change in pattern. Tocodynamometry suggested a transient increase in uterine activity after maximal exercise in 6% of the tests. These findings support the view that strenuous exercise of limited duration is not harmful to the healthy mother and fetus. (Am J Obstet Gynecol 1992;166:854-9.)

Key words: Pregnancy, maximal exercise, blood pressure, electrocardiogram, fetal heart rate

With ever-increasing numbers of pregnant women wanting to participate in sport activities, the question as to how safe maternal exercise is for mother and fetus becomes more important. With regard to the mother, cardiovascular adjustments to strenuous physical activities could be dangerous because of the added burden to an already hyperdynamic maternal circulation. On the other hand, the low resistance of the dilated vascular bed in pregnancy could have a protective effect on the circulation and depress the maternal blood pressure response to exercise.

Physical exercise of the mother presents a potential threat to fetal health because uterine blood flow is known to decrease progressively with exercise intensity.[1] Results of early studies in healthy pregnant women suggested that even mild to moderate exercise may occasionally be associated with fetal bradycardia during exercise,[2, 3] but this finding was later dismissed as representing an artifact.[4] Animal studies have demonstrated that several compensatory mechanisms act

together to preserve fetal oxygen consumption even during exhaustive exercise.[1] These observations provide the justification for a study of maternal and fetal responses to strenuous exercise in healthy pregnant women.

In this study in healthy pregnant women with uncomplicated pregnancy, we assessed some physiologic responses to strenuous bicycle exercise relevant to the safety of the mother and her fetus: maternal electrocardiogram (ECG), blood pressure, uterine contractility, and fetal heart rate (FHR).

Material and methods

We studied 33 women at 16, 25, and 35 weeks' gestation and 7 weeks after delivery. In each study period we measured maternal blood pressure and recorded the ECG at rest and at increasing levels of bicycle exercise until maximal aerobic power was reached; we also recorded FHR and uterine contractility at rest and during recovery. All women were healthy and had uncomplicated singleton pregnancies. The study was approved by the Hospital and University Ethics Committee, and all women included in the study gave their informed consent.

Exercise was performed in an air-conditioned room at 21° C and 55% humidity. All participants underwent a physical and obstetric examination before each test to exclude any abnormality. In addition, we recorded FHR by means of Doppler ultrasound and uterine contractility by external tocodynamometry (model III fetal monitor, Corometrics, Wallingford, Conn.) in the second and third trimesters of pregnancy to ensure fetal well-being.

After 20 minutes of rest in the semisupine position, each woman was asked to sit on a bicycle ergometer (model II FE ergometer 400 L, Mijnhardt, Bunik, The Netherlands). She was connected to a gas flow meter (Oxycon 4, Mijnhardt) for a study of maximal oxygen consumption on which we reported separately.[5] The volunteer was also connected to an ECG monitor (model RM 102, Honeywell, Best, The Netherlands) and a bipolar ECG, lead CM_5, from manubrium to the left precordial position (V5), was continuously recorded (with a Cardiostat, Siemens, Stockholm). We measured blood pressure at 3-minute intervals with a standard sphygmomanometer (Erka-sphygmomanometer, Bad Tolz, Germany) and auscultation using Korotkoff sounds I and V to indicate systolic and diastolic blood pressures, respectively. After 5 minutes of baseline measurements at rest on the ergometer, the woman started to exercise. Three minutes of warming up at 30 W was followed by stepwise increments in exercise intensity of 10 W every 30 seconds until maximal oxygen consumption ($\dot{V}O_2max$) was reached. This was followed by 5 minutes of cooling down at 10 W. The cardiotocogram could not be recorded reliably during exercise, so it was recorded during 20 minutes of recovery with the woman in a semisupine position.

The ECGs were evaluated according to previously established criteria.[6] Mean blood pressures were calculated as $\frac{1}{3} \times$ (Systolic pressure + 2 × Diastolic pressure). The cardiotocograms were evaluated in a blinded fashion with the use of the Fisher score.[7] In addition, we calculated the average basal FHR during the last 5 minutes of rest and the first 5 minutes of recovery with the woman in a semisupine position and measured the frequency of contractions.

For each test period and each variable under consideration we computed mean values and standard errors of the mean. Analysis of variance and Student t tests were used to assess differences between paired variables. A p value of <0.05 was taken as the level of significance.

Results

The 33 women who participated in the study, 23 nulliparous and 10 parous, remained healthy, with uncomplicated pregnancies, throughout the study period, and they were delivered of healthy infants. Maternal age at the time of delivery was 30.9 ± 0.7 years (mean ± SE), gestational age was 40.3 ± 0.2 weeks, and birth weight was 3.43 ± 0.08 kg. Birth weight for gestational age, corrected for parity and fetal sex, was between the 10th and 90th percentiles of the reference curve in 28, <10th percentile in four, and >90th percentile in one infant.

All subjects were studied at 16.1 ± 1.0, 25.3 ± 0.7, and 35.0 ± 0.6 weeks of pregnancy and at 6.7 ± 1.4 weeks after delivery. Mean body weight at 16 weeks' gestation was 68.0 ± 1.7 kg, not different from the postpartum control value of 67.6 ± 1.9 kg, but it increased significantly with advancing gestational age to 71.8 ± 1.8 and 75.3 ± 1.8 kg at 25 and 35 weeks' gestation, respectively.

The values of heart rate at rest and at maximal exercise have been previously reported.[5] Heart rate at rest increased significantly with advancing gestational age from 87 ± 2 beats · min^{-1} at 16 weeks to 89 ± 2 beats · min^{-1} at 25 weeks and to 94 ± 2 beats · min^{-1} at 35 weeks' gestation, as compared with 83 ± 2 beats · min^{-1} post partum. Heart rate showed a linear increase with exercise intensity to a maximum of 174 ± 2 beats · min^{-1} throughout pregnancy and 178 ± 2 beats · min^{-1} post partum, as shown in Fig. 1. Analysis of the resting ECGs for abnormal changes in conduction, repolarization, and rhythm showed no anomalies in 30 women; two demonstrated sinus arrhythmia and one had an ectopic atrial rhythm. During exercise, 28 women had a normal ECG throughout pregnancy and post partum; four subjects showed

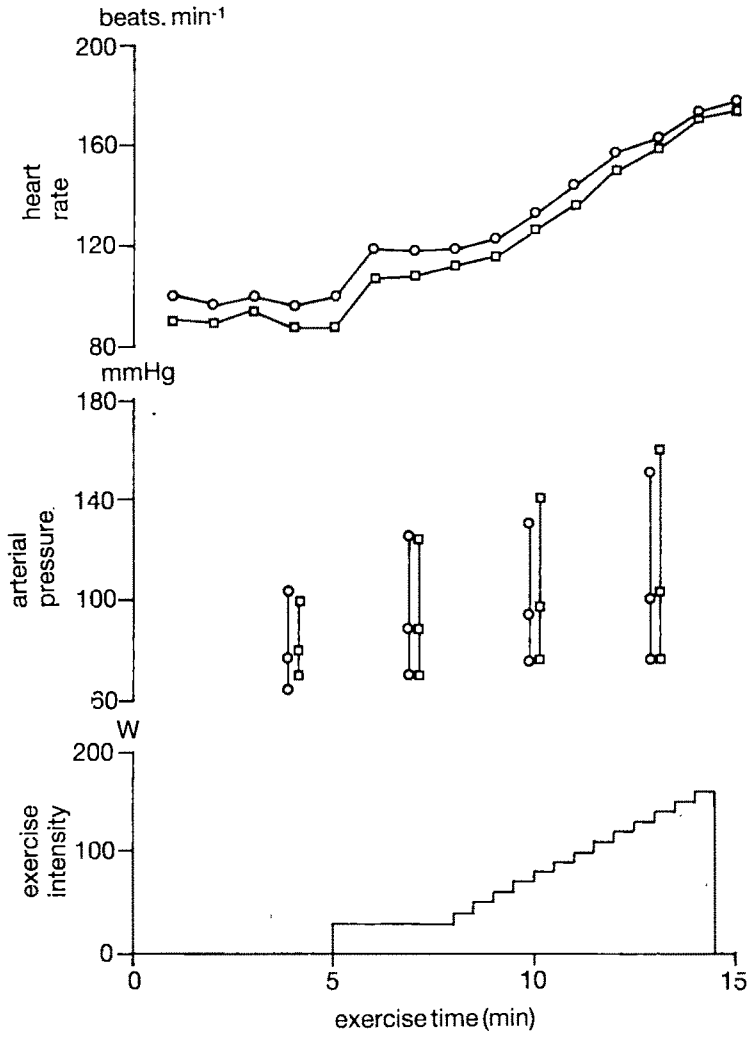

Fig. 1. Rise in heart rate and systolic and mean blood pressures at increasing levels of exercise intensity and absence of change in diastolic blood pressure. ○, First trimester; □, post partum.

depression of the ST segment of ≥0.1 mV, accompanied by an inverted T wave in one subject. Sinus arrhythmia disappeared during exercise in the two women who showed this abnormality at rest, but the ectopic atrial rhythm persisted in one subject. The ECG abnormalities during exercise in these women occurred consistently in all pregnancy and postpartum test periods. None of the 33 women had signs or symptoms suggestive of cardiac ischemia.

Mean values of systolic, diastolic, and mean arterial pressures at rest and at approximately 75% $\dot{V}O_2max$ are shown in Table I. Systolic blood pressures at rest appeared to be unaffected by pregnancy, whereas diastolic and mean pressures were slightly lower during the first and second trimesters of pregnancy as compared with values obtained in the third trimester and post partum. Systolic and mean arterial pressures showed a linear increase with exercise intensity (Fig. 1). At approximately 75% $\dot{V}C_2max$ systolic and mean arterial pressures were significantly increased by an average of 36% and 17%, respectively, whereas diastolic pressures increased marginally by an average of 2%. Mean values of exercise intensity and systolic blood pressure were similar and values of diastolic pressure were slighly lower in the first and second trimesters than in the postpartum period. During the third trimester the average exercise intensity at the time of the measurement was 5% higher and the systolic blood pressure during exercise was 4% higher than in the postpartum period, whereas the diastolic pressure was similar. Except for a marginal difference at 16 weeks' gestation, calculated mean blood pressures during ex-

Table I. Effect of pregnancy on blood pressure at rest and during strenuous bicycle exercise

	Blood pressure (mm Hg)			
	Systolic	*Mean*	*Diastolic*	*Exercise intensity (% $\dot{V}O_2max$)*
At rest				
16 wk	110.0 ± 1.8	85.4 ± 1.3*	73.0 ± 1.2*	—
25 wk	113.0 ± 1.7	87.5 ± 1.1*	74.7 ± 1.0*	—
35 wk	114.8 ± 1.9	90.3 ± 1.3	78.0 ± 1.3	—
Post partum	112.9 ± 1.6	90.6 ± 1.2	79.4 ± 1.1	—
During exercise				
16 wk	150.3 ± 2.7	100.8 ± 1.4†	76.1 ± 1.1*	74.0 ± 1.9
25 wk	153.9 ± 3.0	102.9 ± 1.5	77.4 ± 1.1†	74.5 ± 1.9
35 wk	158.0 ± 3.0*	105.6 ± 1.5	79.4 ± 1.2	76.8 ± 2.0
Post partum	151.5 ± 2.7	103.5 ± 1.3	79.5 ± 1.0	73.1 ± 2.1

Values are mean ± SE. Exercise values are significantly increased above resting values ($p < 0.01$) for all variables except for diastolic blood pressure.

*$p < 0.01$, compared with postpartum control values ($n = 33$).

†$p < 0.05$, compared with postpartum control values ($n = 33$).

ercise in pregnancy were not different from the postpartum value.

Mean FHR during the first 5 minutes after exercise showed a small but significant increase relative to the resting control value observed in the second and third trimesters; in the second trimester it rose from 143.9 ± 0.9 to 148.7 ± 1.5 beats · min^{-1} and in the third trimester from 140.7 ± 1.4 to 144.2 ± 1.8 beats · min^{-1}. The Fisher score could not be established in 10 of the 33 subjects at 25 weeks' gestation because of poor quality of tracings, whereas all 20-minute tracings except one were satisfactory at 35 weeks' gestation. Average scores after exercise were not significantly different from those obtained at rest, both at 25 weeks' gestation (9.7 ± 0.2 and 9.9 ± 0.1, respectively) and at 35 weeks of pregnancy (9.5 ± 0.2 and 9.6 ± 0.2, respectively). At 25 weeks of pregnancy 22 of the remaining 23 fetuses had an optimal score of 8 to 10 points both at rest and after exercise. In one case the score changed from optimal (8 points) at rest to suboptimal (7 points) after exercise. At 35 weeks 30 fetuses were scored as optimal both before and after exercise, one changed from optimal (8 points) to suboptimal (7 points), and one changed from suboptimal (7 points) to optimal (10 points).

Uterine activity was recorded reliably from all subjects in both trimesters. At 25 weeks' gestation 32 of the 33 women showed no uterine activity before or after exercise; in one woman uterine contractility after exercise was not present at rest but was recorded after exercise. At 35 weeks' gestation 27 women had no uterine contractility either before or after the bicycle exercise, three women showed some uterine contractility both before and after exercise, and three women showed a few irregular contractions after exercise, which subsided spontaneously. None of the women noticed the recorded contractions or progressed into labor.

Comment

We observed depression of the ST segment in 12% of the pregnant women studied; similar[8] or much higher figures of up to 75%[9] have been observed in other studies in healthy pregnant women. The cause of these repolarization abnormalities remains unknown; most women with ST depression during exercise testing have angiographically normal coronary arteries.[10] It has been suggested that the ECG changes could be due to altered sympathetic regulation,[10] and one might speculate the ECG abnormalities during exercise may occur more frequently in pregnant women[11] because pregnancy may affect sympathetic regulation.[12] Our findings do not suggest that pregnancy markedly increases the incidence of repolarization abnormalities or arrhythmias in exercising women, but our study does not rule out a possible effect of pregnancy. Our data seem to support, however, the suggestion that exercise electrocardiography is of limited value in healthy pregnant or nonpregnant women.[13]

We used sphygmomanometry and auscultation for the measurement of arterial blood pressure. This method has known limitations with respect to accuracy and precision, in the nonpregnant and pregnant state.[14] However, in this longitudinal study the errors inherent in the method of blood pressure measurement may be expected to have been similar in all test periods, and for that reason it seems unlikely that they have affected pregnancy trends. In the first and second trimesters of pregnancy we found lower diastolic pressures at rest as compared with those observed in the third trimester

and post partum but no significant differences in systolic blood pressure. This is in agreement with the literature and is thought to reflect a reduction in systemic vascular resistance.[14] Systolic arterial pressure increases with exercise intensity, whereas diastolic pressure increases only slightly.[15] Some authors reported a higher systolic pressure response to exercise in pregnant women than in nonpregnant ones,[16] whereas others observed no difference.[17, 18] We found that absolute values of diastolic and mean arterial pressure during exercise were slightly lower during the first and second trimesters of pregnancy, which may reflect the lower resting values observed during these periods. Systolic blood pressure during exercise differed from that in the postpartum period only in the third trimester of pregnancy, when it was significantly increased by 4%, or 6 mm Hg. This may reflect the cumulative effect of the 2% higher systolic pressure at rest and the 5% higher exercise intensity during the third trimester in this study rather than a physiologically important difference in response. The observation that the blood pressure response to exercise is virtually unaffected by pregnancy in spite of the hyperdynamic circulation suggests that the pressure response is governed by local demand.

The FHR response to moderately strenuous maternal exercise has been investigated repeatedly since it was proposed as a clinical test for uteroplacental insufficiency.[19] We consistently observed an elevated basal FHR after the maximal bicycle test. This probably reflects the increase in body temperature rather than fetal distress and confirms similar observations after less strenuous exercise.[20, 21] Although abnormal heart rate patterns, including bradycardia, have been reported during exercise,[2, 3] other studies have adduced evidence that these abnormal patterns are artifacts caused by rhythmic maternal movements during exercise.[4] During recovery from exercise such artifacts are less likely to occur. Fetal bradycardia has been reported to persist occasionally for 4 minutes after exercise,[2] and one study reported a 19% incidence of fetal bradycardia (defined as a heart rate <110 beats/min for ≥ 10 seconds) within a few minutes after maximal maternal exercise before return to a normal heart rate.[22] One may only speculate as to what may have caused these changes. We were unable to record FHR reliably during the bicycle test but found the pattern unchanged after exercise and 5 minutes of cooling down. We did not measure FHR within 5 minutes of maximal effort. However, with the use of invasive techniques it has been demonstrated that even exercise at the point of exhaustion has little effect on FHR in experimental animals and that fetal blood gas values remain within normal limits.[23]

We observed uterine contractility after exercise in some women. This is in agreement with observations by others who reported either occasional slight increases[24] or no change[25] in uterine contractility in response to physical activity, without progression into labor.

In conclusion, we obtained no evidence that strenuous exercise of limited duration in pregnancy markedly modulates the ECG or blood pressure response or affects the FHR pattern. The safety to the healthy mother and fetus of strenuous exercise of long duration remains to be studied.

We thank Dr. K.F. Kerrebijn for making the laboratory facilities available to us and Mr. J.M. den Ouden for technical assistance.

Is trichomoniasis often associated with bacterial vaginosis in pregnant adolescents?

Janine A. James, MD, Jessica L. Thomason, MD, Sheldon M. Gelbart, PhD, Peter Osypowski, MT(ASCP), Paul Kaiser, RN, CNM, and Lisa Hanson, RN, CNM

Milwaukee, Wisconsin

The same criteria for identifying bacterial vaginosis are often present in women with trichomoniasis. These criteria include elevated vaginal pH, vaginal odor, homogeneous discharge, increased anaerobic bacteriologic vaginal flora, and elevated levels of bacterial enzymes. Clinically mixed vaginal infections occur, and because the treatment for these two conditions can be different, it is important to distinguish between them. Trichomoniasis can interfere with a Gram stain diagnosis or the proline aminopeptidase test for bacterial vaginosis. Clue cells are not generally found in women with *Trichomonas vaginalis*, but when present, they strongly indicate the concomitant presence of bacterial vaginosis. (AM J OBSTET GYNECOL 1992;166:859-63.)

Key words: Bacterial vaginosis, trichomoniasis, clue cells

Older studies report an association between trichomoniasis and bacterial vaginosis, with as many as 80% of women infected with *Trichomonas vaginalis* also being diagnosed with bacterial vaginosis.[1-3] For the diagnosis of bacterial vaginosis, Amsel's classic criteria and, more recently, other more accurate criteria have been identified to objectively and rapidly make a correct diagnosis.[4-6]

Bacterial vaginosis is a condition in which there is a grossly abnormal vaginal ecosystem with a predominance of anaerobic flora and decreased lactobacillus species, creating an environment conducive to anaerobic proliferation. *T. vaginalis* is an anaerobic protozoan capable of creating and thriving in an anaerobic milieu. Trichomonads contain granules called hydrogenosomes, which generate hydrogen. Hydrogen combines with oxygen to form water, thereby removing oxygen from the vaginal ecosystem.[7] This mechanism stimu-

lates and facilitates the growth of other anaerobic bacteria.[8]

Mixed vaginal infections are seen frequently in clinical practice, especially in sexually transmitted disease clinics.[2] It is unclear, when two or more types of vaginitis occur in an individual, whether criteria used to diagnose one type of vaginitis are affected by the presence of another pathogen (i.e., bacterial vaginosis in the presence of trichomoniasis). It has been established that if women do not undergo culturing for *T. vaginalis*, the disease will be underdiagnosed, making study analysis of patient groups difficult. The purpose of this study was to clarify the interrelationship between trichomoniasis and bacterial vaginosis. Trichomonads cause some manifestations seen in bacterial vaginosis, but conceptually there are two distinct entities that should be able to be differentiated. Six different diagnostic methods are currently in use to diagnose bacterial vaginosis. All methods were studied to see how the presence of trichomoniasis affects each of these various criteria.

Material and methods

After informed consent was obtained, 142 consecutive pregnant teenagers were tested for both bacterial vaginosis and trichomoniasis and for sexually transmitted diseases at their initial visit to the Adolescent Pregnancy Program at Sinai Samaritan Medical Center between March 1989 and March 1990. All but 33 were primigravid with a mean age of 15.9 ± 1.82 years. The mean gestation when they were first seen was 17.4 ± 8.8 weeks. Median gravidity was 1, parity 0, abortion 0.

Trichomonads were detected by two methods: analysis of saline solution wet mounts of vaginal secretion and by culture of vaginal secretions in Diamond's medium modified (Remel, Lenexa, Kan.). Wet mounts were prepared by placing a saline solution–moistened, cotton-tipped swab containing vaginal secretions, obtained from the lateral walls of the anterior vaginal fornices, into 1.0 ml of physiologic saline solution. A drop of this suspension was placed on a slide and a coverslip was added. Examination was made at a magnification of ×100 with >20 fields being examined. Any suspicious elements were examined at a magnification of ×400. Only motile trichomonads were counted. Wet mounts were prepared within 15 minutes of collection and analyzed immediately. The swab was then placed into trichomonas culture medium and incubated at 35° ± 2° C under 5% to 7% carbon dioxide at 80% humidity. The medium was examined at 2, 4, and 7 days for motile organisms.

Bacterial vaginosis was detected by six methods. Two clinical methods (Amsel et al.[3] and Thomason et al.[6]), three Gram stain interpretative methods (Spiegel et al.,[4] Nugent et al.,[5] and a new rapid semiquantitative method), and a proline aminopeptidase assay[9] were used. Vaginal secretions were collected as previously described, and wet mounts were examined at a magnification of ×400 for clue cells.[6] Odor was tested by immersing a swab containing freshly collected vaginal secretions into 1.0 ml of 10% potassium hydroxide and then smelling the swab. Only a distinctly fishlike odor was considered positive. The pH of vaginal secretions was measured with phenaphthazine paper (Nitrazine paper, E.R. Squibb and Sons, Princeton, N.J.). The presence of homogeneous discharge was noted during routine pelvic examination. The criteria of Amsel et al. for bacterial vaginosis include three of four diagnostic signs: presence of homogeneous discharge, pH >4.5, positive amine odor, and presence of clue cells on wet preparation.[2] Criteria of Thomason et al. include the presence of clue cells on microscopic analysis of vaginal secretions.[6]

Gram stains were made from smears of vaginal secretions. For the Spiegel and Nugent method at a magnification of ×1000, the following coding scheme was used: 1+, less than one organism per field; 2+, one to five organisms per field; 3+, six to 30 organisms per field; 4+, >30 organisms per field. Patients were considered to have bacterial vaginosis by the Spiegel method of interpretation if lactobacillus morphotypes were <2+, *Gardnerella* morphotypes were 4+, and at least one other morphotype was present.[4] Patients were considered to have bacterial vaginosis by the Nugent Gram stain method if the following criteria were met: Numeric values were assigned to each quantitation of morphotype, specifically, 4+ lactobacilli = 0, 3+ lactobacilli = 1, 2+ lactobacilli = 2, 1+ lactobacilli = 3, no lactobacilli = 4, 1+ *Gardnerella* = 1, 2+ *Gardnerella* = 2, 3+ *Gardnerella* = 3, 4+ *Gardnerella* = 4, 1 to 2+ *Mobiluncus* = 1, 3 to 4+ *Mobiluncus* = 2. If the number achieved from the counts of these three morphotypes was 7 to 10, the patient was diagnosed as having bacterial vaginosis. If the counts gave a numeric value of 4 to 6, the patient's flora was considered intermediate, and if the counts gave a numeric value of 0 to 3, bacterial vaginosis was excluded.[5] In addition, all Gram stains were examined for the presence of clue cells. A semiquantitative Gram stain was also used. If clue cells were present and nonlactobacillus morphotypes exceeded lactobacillus morphotypes, bacterial vaginosis was diagnosed.

The proline aminopeptidase assay was performed as originally described.[9] Briefly, a cotton-tipped swab containing vaginal secretions was placed into 1.2 ml saline solution and agitated to suspend the vaginal material. The swab was removed and the suspension was centrifuged at 8730*g* for 2.5 minutes on a Microfuge (Beckman, Palo Alto, Calif.) to pellet the suspension. All but 0.1 ml of the supernatant was discarded. The pellet was then resuspended and 0.05 ml was added to a microtiter

well containing 0.05 ml of 0.2% L-proline β-naphthylamide (Sigma, St. Louis). The trays were covered to prevent evaporation and incubated at 35° ± 2° C for 4 hours. Then 0.05 ml of 0.015% fast garnet GBC salt (Sigma) was added to the well to detect β-naphthylamine and read visually for red color after 5 minutes.

χ^2 Statistical methods were used to analyze data. Both McNemar and Fisher tests were used where appropriate.

Results

Of the 142 teens surveyed, 22 (15%) were excluded because of having simultaneous chlamydia or gonorrhea. Women with vaginal yeast infections were not excluded because it has been shown that yeasts do not affect the diagnosis of either trichomoniasis or bacterial vaginosis.[9,10] Thirty-two of 120 evaluable teens (26.6%) were found to have trichomonads by culture. Only 25 cases of trichomoniasis, 78% of those diagnosed by culture, were also diagnosed by wet mount examination ($p < 0.05$, McNemar χ^2). No teens with positive wet mounts for trichomonads had negative cultures.

Table I shows the association between various diagnostic criteria used to identify women with bacterial vaginosis and trichomoniasis in the 120 evaluable teens. Of the 88 patients who had no trichomonads (Table I, column 2), a subset of 59 teens had no trichomonads by culture and no bacterial vaginosis (defined by criteria of Amsel et al.). This group's characteristics are shown in Table II.

*Bacterial vaginosis diagnosed by criteria of Amsel et al.

Teens with trichomonads (Table I) were less likely to have odor on alkalinization of vaginal secretions than teens without trichomonads ($p < 0.05$, Fisher) and slightly more likely to have homogeneous discharge, although this finding was not significant ($p > 0.05$, Fisher). Clue cells in wet mount examination were found in only two teens with trichomonads, both of whom had bacterial vaginosis by all diagnostic methods used.

There was evidence of change in the bacterial flora, with teens having trichomonads significantly more likely to have nonlactobacilli morphotypes predominating when compared with the group of teens in Table II ($p < 0.05$, Fisher). Twenty teens with trichomonads had positive proline aminopeptidase results, but only seven had bacterial vaginosis by any criteria used. Women with trichomonads consistently had leukocytes exceeding vaginal epithelial cells when compared with the teens in Table II (53% vs 34%, $p < 0.05$, Fisher).

Only seven teens having trichomonads were simultaneously diagnosed with bacterial vaginosis by criteria of Amsel et al. (Table I). All had positive results by proline aminopeptidase. Of significant interest is the fact that only two (2/32) teens with trichomoniasis had clue cells. All women with trichomonal vaginitis who had clue cells in secretions also had concomitant bacterial vaginosis by any of the six methods used to diagnose bacterial vaginosis.

From the total 120 evaluable teens, 36 women were diagnosed as having bacterial vaginosis with the criteria

*Eleven women also had intermediate flora.

of Amsel et al. and 31 of 36 would have met the criteria of bacterial vaginosis by Thomason et al. (clue cells in wet mounts) (Table III). There were 13 (13/36) women with bacterial vaginosis who had all of the four diagnostic characteristics of Amsel et al. All women in this study who had clue cells on wet mount also had clue cells on Gram stain, but six additional patients had clue cells on Gram stain yet did not meet any criteria for bacterial vaginosis nor have trichomonads by culture.

Thirty-nine women had bacterial vaginosis by Spiegel's Gram stain, including 30 of 31 who had clue cells on wet mount (Table III). Nugent's Gram stain method showed 34 teens with bacterial vaginosis but also showed 11 with intermediate classification, eight of whom had trichomonads. There were 88 teens who had nonlactobacilli morphotypes exceeding lactobacilli types, but if the two criteria, clue cells on Gram stain and nonlactobacilli morphotypes exceeding lactobacilli on Gram stain, were combined, 36 women were identified, 31 of whom had bacteria vaginosis by criteria of both Amsel et al. and Thomason et al.

Forty-nine (49/120, 41%) women had positive test results by the proline aminopeptidase assay. Sixty-two percent (20/32) of women having trichomonads were also found to have a positive proline aminopeptidase assay, although only seven of this group had concomitant bacterial vaginosis by criteria of Amsel et al. (Table I). One teen with a positive result by proline aminopeptidase had neither trichomonads nor bacterial vaginosis by any of the other methods. Proline aminopeptidase accurately identified 89% (32/36) of women having bacterial vaginosis by the criteria of Amsel et al. in this study and 97% (30/31) having bacterial vaginosis by criteria of Thomason et al. (Table III).

Comment

The association of trichomoniasis and bacterial vaginosis (7/32, 22%) diagnosed with classic criteria in asymptomatic pregnant teens was not as great as previously reported in symptomatic women[1] or in women attending sexually transmitted disease clinics.[3] Study patients were all pregnant, and the effect pregnancy has on the association between trichomoniasis and bacterial vaginosis is not known. Nearly half of the women with trichomoniasis lacked increased levels of white blood cells in vaginal secretions. However, if trichomonads were detectable on wet mount, white blood cells were elevated in 68% (17/28) of cases. Women with trichomoniasis nearly always had abnormal bacterial flora, i.e., lactobacilli morphotypes were outnumbered by nonlactobacilli morphotypes. Of significance is the finding of a lack of clue cells in teens having *T. vaginalis* in secretions. On the contrary, if clue cells were present in teens with trichomoniasis, all had bacterial vaginosis. Certainly, if an observer finds trichomonads and clue cells during microscopic examination of vaginal secretions, other criteria for bacterial vaginosis should be sought.

Homogeneous discharge and vaginal pH continue to be diagnostic signs that lack specificity, as has been suggested in previous studies.[6, 10, 11] Our data in Table II confirm this finding. Observer bias and pH differences in sample sites may account for these factors being present in a large number of women without *T. vaginalis* or bacterial vaginosis. Many women during pregnancy complain of an increased amount of vaginal discharge, and this may simply reflect hormonal changes with increased vascularity present in the lower genital tract during this time period. Perhaps this explains why 68% of our population were found to have homogeneous discharge.

Bacterial vaginosis was found in 30% (36/120) of our teens, yet the predominance of nonlactomorphotypes (73%, 88/120) was seen even more frequently. This criterion is easily identified on Gram stain and wet preparation analysis of vaginal secretions. However, this study confirms previous work that using this single criterion on Gram stain or Papanicolaou smear to accurately predict bacterial vaginosis would result in overcalling the diagnosis of bacterial vaginosis.[6] In Table II this single criterion would have falsely identified nearly half of these adolescents as having bacterial vaginosis.

Proline aminopeptidase is a rapid, objective biochemical test that has a positive result in women having bacterial vaginosis.[9] The data in this study show that this assay is affected by trichomonads, presumably because of the changes in bacterial flora induced by *T. vaginalis* when it removes the oxygen from the vaginal environment. Vander Meijden et al.[12] have shown that the microbial flora in bacterial vaginosis and trichomoniasis is similar. This may explain our finding of bacterial flora in trichomoniasis causing a positive proline test. In this

study 4-hour incubation with substrate was used for the proline aminopeptidase assay. Shortening the incubation time might alleviate the problem of false-positive results caused by trichomonads. However, clinicians should be aware of the high false-positive rate of this test seen in women having *T. vaginalis* alone and not bacterial vaginosis in vaginal secretions. Concomitant wet mount examination of vaginal secretions is always prudent before proline aminopeptidase is used as a screening tool for the identification of women having bacterial vaginosis.

In conclusion, in a population that had cultures for *T. vaginalis,* this protozoan was not frequently associated with bacterial vaginosis. Such women may have some of the characteristics that meet the criteria for bacterial vaginosis, such as profuse discharge with odor or elevated vaginal pH, but they usually have no clue cells. The absence of clue cells strongly suggests that these women do not have bacterial vaginosis.[6, 10, 11, 13] However, if women who have trichomonads in secretions also have clue cells, bacterial vaginosis should be strongly suspected. Bacterial vaginosis has been associated with both premature rupture of membranes and premature labor, and therapy in such patients should be considered.[11, 13] Single-dose metronidazole therapy, while effective for trichomoniasis, is not effective for bacterial vaginosis.[11] Similarly, because there is a change in bacterial flora induced by trichomonads, both the Spiegel et al. and Nugent et al. Gram stain interpretations used for diagnosis of bacterial vaginosis, and also the proline aminopeptidase assay can give false-positive diagnoses for bacterial vaginosis when trichomonads are present. In contrast, concomitant yeast infection does not influence bacterial flora and therefore affects neither clinical criteria for bacterial vaginosis nor the Gram stain diagnostic method nor the proline aminopeptidase assay.[9] Because trichomoniasis can cause false diagnoses of bacterial vaginosis, women treated with clindamycin for bacterial vaginosis who fail to respond should be tested for trichomoniasis and treated with metronidazole if trichomonads are found, because clindamycin has no effect on *T. vaginalis.*

Laparoscopic radical hysterectomy with paraaortic and pelvic node dissection

Camran R. Nezhat, MD,[a, b] Matthew O. Burrell, MD,[c] Farr R. Nezhat, MD,[a, b] Benedict B. Benigno, MD,[c] and Charles E. Welander, MD[c]

Macon and Atlanta, Georgia

We report the first case of a laparoscopic radical hysterectomy and paraaortic and pelvic lymphadenectomy to treat a stage IA2 carcinoma of the cervix. To our knowledge, a laparoscopic radical hysterectomy with laparoscopic paraaortic lymphadenectomy has not been previously described. (AM J OBSTET GYNECOL 1992;166:864-5.)

Key words: Laparoscopy, paraaortic node dissection, radical hysterectomy

We report the first case of a laparoscopic radical hysterectomy and paraaortic and pelvic lymphadenectomy to treat a stage IA2 carcinoma of the cervix.

Case report

A 30-year-old woman, gravida 3, para 2-0-0-2, was evaluated at 12 weeks' gestation for an abnormal Papanicolaou smear. Colposcopic examination was satisfactory and findings were consistent with dysplasia. No areas suspicious for invasion were noted. Biopsy revealed grade 3 cervical intraepithelial neoplasia. She underwent follow-up during pregnancy with colposcopy and biopsy without evidence of invasion and was delivered by repeat cesarean section.

Laser conization (6 weeks post partum) revealed cervical intraepithelial neoplasia with a 2.74 mm focus of invasion with lymphatic space involvement and a width of 3 cm. Lymphatic space involvement by tumor cells put this patient at higher risk for metastases and consequently made her a candidate for radical hysterectomy. Physical examination revealed a healthy young woman, 5 feet 8 inches tall, weighing 199 pounds, with a history of three cesarean sections.

A standard bowel preparation was used and she received three 2 gm doses of cefoxitin prophylactically.

During the laparoscopic portion of the procedure all pedicles were coagulated with bipolar cautery and incised with the carbon dioxide laser.[1] Sutures were not required and peritoneal incisions were allowed to heal secondarily.

For the right common iliac and lower paraaortic lymphadenectomy, the patient was tilted to the left side and placed into the deep Trendelenburg position at 35 to 40 degrees. The ureter was identified through the peritoneum. An opening was made into the peritoneum just above the sacral promontory; with hydrodissection[2] the retroperitoneal space was injected with lactated Ringer's solution and then incised with the carbon dioxide laser toward the duodenal bulb.[2] The common iliac and paraaortic nodes were removed from the veins' surface by blunt dissection, hydrodissection, and the carbon dioxide laser.[1] Larger bleeders, such as the venous perforators of the vena cava, were coagulated first with bipolar cautery.[1] The ureter was identified immediately next to the vena cava, and dissection was taken to 2 cm above the aortic bifurcation. Then the rectovaginal, paravesical, and pararectal spaces were dissected. The rectum was dissected off the posterior vaginal wall. This was taken to 5 cm below the cervix. The round ligaments were coagulated close to the pelvic sidewalls and transected. The peritoneum was opened and the paravesical and pararectal spaces were dissected out, allowing excellent skeletonization of the obliterated hypogastric artery.[2] The uterine vessels were identified, skeletonized, coagulated medial to their origin, and transected, then rotated anterior to the ureters.[2]

The vesicovaginal space was developed using techniques described above, with difficulty because of scarring from three previous cesarean sections.[2]

The uterine vessel was disseted medially for 4 cm and elevated from the ureter using the carbon dioxide laser. The anterior parametrium was transected, and the ureters were freed from the peritoneum and skeletonized down to the bladder. The uteroovarian pedicles were coagulated and transected.[1]

The left common iliac nodes, with the left pelvic nodes, were removed as on the right side.

The external iliac nodes between the external iliac vein and artery and the obliterated hypogastric artery were carefully stripped to the deep circumflex veins. The obturator nerve was exposed and the hypogastric and obturator nodes were removed. The obturator nerve was dissected and cleaned caudally to the point

6/1/34742

at which it left the pelvis. The nodal tissue between the obturator nerve and external iliac vein was dissected. The inferior aspect of the external iliac vein was separated until the internal obturator muscle and pelvic bone were seen. Venous anastomosis between obturator and external iliac veins was visualized and retained. Lymph nodes posterior to the obturator nerve were excised. The uterosacral ligaments and lateral parametria were coagulated and sequentially transected approximately 1.5 cm lateral to the cervix. The dissection was taken down to 3 cm below the cervix. The vagina was entered anteriorly and posteriorly. Sponges in the vagina prevented loss of pneumoperitoneum.

The radical hysterectomy was completed vaginally by incising the vagina 3 cm distal to the cervix. After anterior and posterior mobilization, the residual cardinal ligaments were divided approximately 1.5 cm lateral to the cervix and then ligated with sutures.[1] The uterus and pelvic nodes were removed transvaginally.[1] The vaginal vault was then closed and a suprapubic catheter was placed.

The procedure lasted 7 hours with an estimated blood loss of 30 ml. The patient began eating within 24 hours and was discharged in 48 hours. The suprapubic catheter was removed in the office 7 days after operation.

The final pathologic examination revealed no residual cancer. All lymph nodes were negative. Of five paraaortic nodes removed, the largest was 1.5 cm and total tissue measured 4 × 3 × 3 cm. Nine left pelvic nodes were removed; the largest was 2.5 cm and total measurement was 6 × 5 × 2 cm. The five nodes removed from the right pelvic area totaled 5.5 × 2 cm; the largest was 1.3 cm. The measurement from the vaginal cuff's lower portion to the superior portion of the uterine fundus was 10.5 cm, and the uterine fundus was 5 × 5 cm wide. The hysterectomy specimen weighed 118 gm.

Comment

Before fair assessment of morbidity from operative laparoscopy can be made, more experience with similar cases is necessary. Only time will show if this case remains a surgical curiosity or whether the procedure becomes commonplace in the future.

Addendum

Since submitting this article, we have performed another laparoscopic radical hysterectomy with paraaortic and pelvic node dissection. The patient was 31 years old, gravida 0, with stage IA2 squamous cell carcinoma of the cervix. A total of 25 pelvic nodes (15 right, 10 left) and 9 paraaortic nodes were removed. Additional specimens included vaginal cuff measuring 3 cm in length and 3 cm of parametrium. The duration of the procedure was 6 hours. No intraoperative or postoperative complications were noted. She was discharged on the second postoperative day. Four months after operation the patient is doing well and shows no sign of recurrent malignancy.

Emergency room use of transvaginal ultrasonography by obstetrics and gynecology residents

Ilan Timor-Tritsch, MD, Susan Greenidge, MD, Dahlia Admon, MD, and M. Lynne Reuss, MD

New York, New York

OBJECTIVE: The objective of this study was to evaluate the feasibility and diagnostic value of the emergency room use of transvaginal ultrasonography operated by the obstetrics and gynecology residents.

STUDY DESIGN: One hundred sixty-eight patients scanned in the emergency room constituted the study group and were compared with 61 patients for whom emergency room scanning was not available. Scanning and no-scanning days alternated for a 6-month period. The Student *t* test was used in the analysis.

RESULTS: By comparing the two patient groups a statistically significant ($p < 0.0001$) difference was seen in the time spent by the group of patients scanned in the emergency room (40 minutes) when compared with that of the patients for whom no emergency room scanning was available (215 minutes). The residents expressed high confidence in the scanning procedure. There were six misdiagnosed cases, three of them nonruptured ectopic gestations. However, none of these patients was discharged without adequate treatment.

CONCLUSION: The study confirmed our hypothesis that obstetrics and gynecology residents can operate and should have available ultrasonography machines in the emergency departments to render quicker and better patient care. (AM J OBSTET GYNECOL 1992;166:866-72.)

Key words: Emergency room, transvaginal ultrasonography

For the past 10 years transabdominal ultrasonography has been actively used in the labor and delivery suites, has become a component part of resident education,[1] and has been successfully applied in emergency room care of women. Jehle et al.[2] reported on a study in which transabdominal ultrasonography was used by emergency room physicians to correctly diagnose, among nonobstetric problems, the presence or absence of intrauterine pregnancy in patients with lower abdominal complaints. The authors concluded that ultrasonography improved the diagnosis and treatment of a large number of patients and suggested that it should become a standard part of emergency room care. Later, Stabile et al.,[3] Grumbach et al.,[4] and Shea and Aghababian[5] also evaluated the frequency of abdominal and pelvic ultrasonography use in the emergency department. These authors found that the use of ultrasonography allowed for faster and safer discharge of patients. Furthermore, they found it to be cost-effective and helpful because many patients who normally would be admitted for observation, further laboratory testing, or operative techniques, could be discharged. Other publications confirmed the importance of ultrasonography in emergency rooms.[6-8]

Ultrasonography has been designated by the Council on Resident Education in Obstetrics and Gynecology as a component of resident education. Thus this laboratory instrument becomes fully integrated into acceptable patient care routines. However, the boundaries for its use should be established, and with this in mind we chose to look at the emergency room use of vaginal ultrasonography.

The American College of Emergency Physicians issued a position statement on the use of ultrasonography for emergency department patients.[9] They stressed the time dependency of the diagnosis in patients seen in the emergency room, i.e., life-threatening situations, urgent cases, and nonemergency cases in which ultrasonography is used as a procedural aid. Patients with a suspected ectopic pregnancy are part of the first two categories and therefore should be scanned in the emergency room.

Our hypothesis was that the availability of an ultrasonography machine in the majority of obstetrics and gynecology patients seen in the emergency room would enable the provider to spend less time in reaching the diagnosis and confirm the one previously made.

Residents in our department were being trained in the use of ultrasonography in general and transvaginal ultrasonography in particular. It was our belief that most residents mastered the technique in a short time,

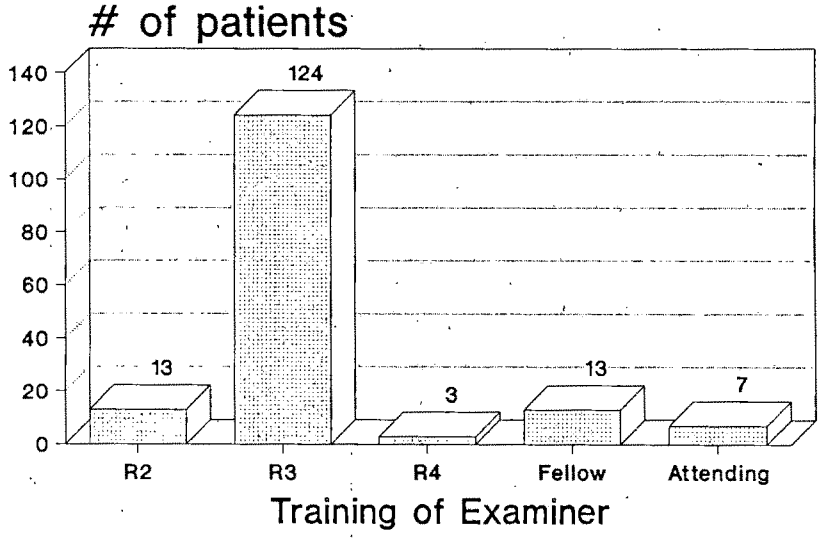

Fig. 1. Who performed the scan (n = 160)?

and they were able to perform transabdominal and transvaginal ultrasonographic examinations at a level that allowed them to incorporate the device into their routine in the emergency room history, physical examination, and laboratory studies. Thus the study was based on evaluating resident performance.

Material and methods

A Hewlett Packard (HP Co., Melville, N.Y.) Research and Development scanner with both a 3.5 MHz mechanical abdominal probe and a 6.5 MHz vaginal probe were used. The images were recorded on a Sony P-61 thermal video printer. The study period was 6 months, from April to September 1990. Two groups were created by alternating scanning days with no-scanning days. On the scanning days the patients were examined in the usual fashion by the residents. If an abdominal or transvaginal ultrasonographic examination was needed, this was performed by that resident. A report was then generated and a study questionnaire was completed. Consultation was available, if requested, during working hours.

On the no-scanning days patients were managed in the usual fashion customary before the ultrasonography unit was placed in the emergency room. If there was no emergency, an appointment for a later scan was given by the resident establishing a working diagnosis. If the patient required an ultrasonography examination, she was taken by that resident to the ultrasonography unit situated on the twelfth floor of the same building. After hours, the patient was either scanned when a consultation was available, admitted for observation if necessary, or discharged for ambulatory follow-up if the level of concern was such that delay in confirming the diagnosis would not place the patient at risk. The time spent by the patient in the emergency room and the time of admission or discharge after a final diagnosis was given were also recorded. The patients were followed up to establish the validity of the final diagnosis and the treatment, as well as the time of the final treatment received by the patient. The questionnaire had the following 14 components:

1. Length of time until final clinical diagnosis was achieved
2. Was it a scanning or no-scanning day?
3. Diagnosis before ultrasonography if on scanning day
4. Was the diagnosis changed after ultrasonography?
5. Did ultrasonography confirm the working diagnosis?
6. Was the management changed after ultrasonography?
7. Was an ultrasonography consultation obtained to clarify the situation?
8. Who performed the ultrasonographic examination?
9. Time of day that examination was done
10. Length of time in minutes to perform the scan
11. Was the scan abdominal, vaginal, or both?
12. The resident's opinion about whether it helped the diagnosis
13. The resident's evaluation of whether it was helpful for the provider
14. The level of confidence of the provider administering the ultrasonographic examination

On the scanning days, 168 patients were scanned and 61 patients constituted the control group seen in the emergency room on the no-scanning days. Most of the time all questions were answered by the scanning person; however, in a minority of the cases one or another question was answered in a fashion that could not be

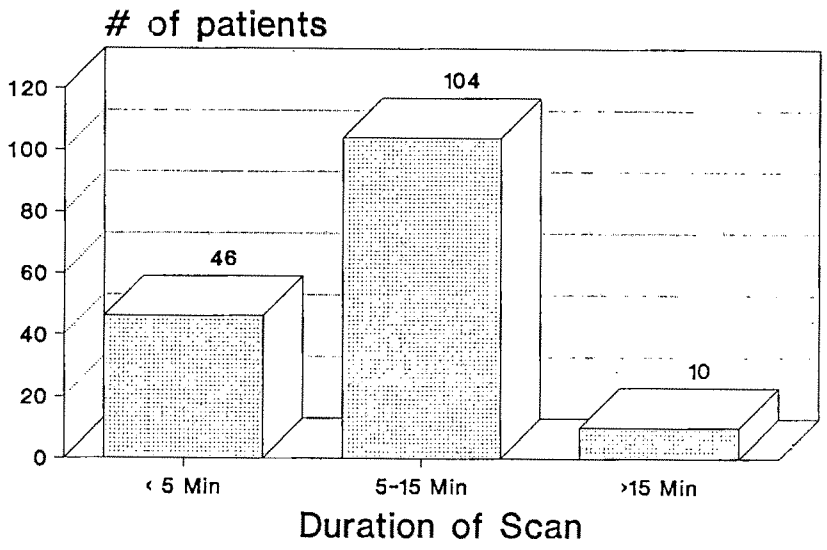

Fig. 2. Duration of scans (n = 160).

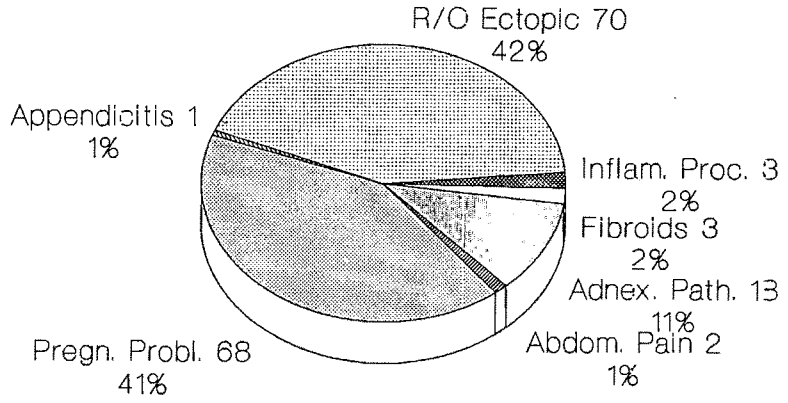

Fig. 3. Diagnosis before scans (on scanning days) (n = 167).

evaluated by us. Thus some graphs have slightly different patient counts. The discrepancy between the study and control group stems from the fact that 3 months after the beginning of the study the residents found ways to scan patients on the no-scanning days. Therefore we used the 61 controls that were handled according to the basic requirements of the protocol so that the study and control groups remained statistically comparable.

Thirteen patients were scanned by a second-year resident, 124 by a third-year resident, and three by a fourth-year resident (Fig. 1). Thirteen patients were scanned by fellows and seven by first-year attending physicians (who were chief residents in the first half of the study). Seventy-four scans were done from 8 AM to 5 PM. Fifty-six patients were scanned at night and 30 over a weekend. Abdominal scanning was done in 21 patients, transvaginal in 113, and both modalities in 21. The scanning lasted <5 minutes in 46 patients, 5 to 15 minutes in 104, and >15 in 10 (Fig. 2). The reasons for the patients being scanned <5 and >15 minutes are presented in the Results section. The diagnosis before and after the scans on the scanning days is shown in Figs. 3 and 4. Sixty-eight patients had pregnancy problems, 70 patients were scanned to rule out ectopic pregnancy, and there were 10 patients with various pelvic disorders. The data were processed by the statistical package SSP version 4 (SPSS Inc., Chicago) and displayed by the Harvard Graphics package (Harvard Graphics SPC Software, Mountain View, Calif.).

Results

One hundred sixty-eight patients were scanned on the scanning days. Of these patients 83% had suspected pregnancy problems or ectopic pregnancies (Fig. 3). After the scans, 53 intrauterine pregnancies were diagnosed, eight ectopic pregnancies were found, a normal pelvis was diagnosed in 26 patients, and six ovarian

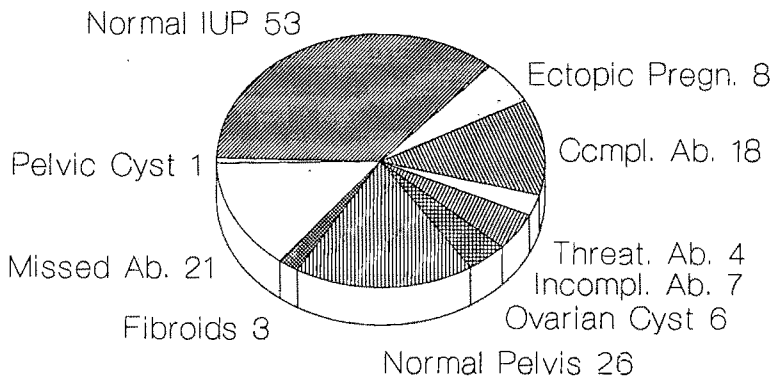

Fig. 4. Diagnosis after scans (all cases) (n = 166).

cysts and one pelvic inclusion cyst were seen. Fifty-two various pathologic conditions of pregnancy were diagnosed, such as complete, incomplete, threatened, and missed abortions (Fig. 4). The breakdown of the diagnoses in the control group (n = 61) was similar to the diagnoses in the scanned group. Most of the patients in whom the examination lasted <5 minutes had suspected pregnancy problems or suspected ectopic pregnancies. The results of the short scan showed normal pregnancies and pathologic pregnancies in most of these cases and only one ectopic pregnancy with a live fetus. All these diagnoses could be made in <5 minutes by using transvaginal ultrasonography. Ten patients were scanned >15 minutes. Seven of them had suspected ectopic pregnancies, two suspected fibroids, and one ovarian torsion.

On the scanning days 76 patients were discharged sooner, 14 patients were admitted earlier, and 14 received surgical treatment sooner. In 53 patients the residents thought that the scan did not change the management of their care. To ascertain that the scanned and the nonscanned patient populations were the same, we looked at the 61 patients who were not scanned. In 43 of the 61 the initial working diagnosis was changed after further diagnostic tests were performed. To answer whether the scans helped the examiner, we evaluated 160 responses. In 121 patients the residents believed management was quicker than usual; in five patients, establishing the diagnosis took a longer time, and in 34 patients the residents thought that the time required to make the diagnosis with or without a scan would have been the same. For the question of whether ultrasonography made the diagnosis more complicated, easier, or the same as without the scan, only four of the 159 questionnaires reflected a more complicated diagnostic process with the scans. In 126 the diagnosis was made easier, and in 29 the residents thought that ultrasonography made no difference in establishing the diagnosis. In 158 questionnaires the residents evaluated their own confidence level. One hundred fifteen felt highly confident with the ultrasonographic examination done in the emergency room, 33 had intermediate and nine low confidence, and in one case the resident was not sure about the level of confidence.

The time spent by the patient in the emergency suite before the diagnosis was reached was 34 minutes in the study group and 215 minutes in the control group (Fig. 5). This was found to be a significant difference at the level of $p < 0.0001$. To arrive at the diagnosis of ectopic gestation took 40 minutes on the scanning days (n = 8) and 190 minutes on nonscanning days (n = 4) (Fig. 6).

There were six missed diagnoses in the scanned group; one normal pregnancy and one complete abortion turned out to be incomplete abortions. The left adnexal mass was diagnosed during surgery as an appendiceal abscess. Three ectopic pregnancies were missed: One was diagnosed as a complete abortion, in the second a normal pelvis was suggested, and the third was labeled as a missed abortion. None of the ectopic pregnancies ruptured, and no patients were discharged home before the correct diagnosis was made, by means of β-human chorionic gonadotropin levels and a repeat sonogram, and treatment was rendered.

Comment

The American College of Obstetricians and Gynecologists issued suggested guidelines for training in ultrasonography.[10] An article was presented at a national meeting[1] and a review article was published to emphasize the use of ultrasonography in the delivery room.[11] It was clear that there was a growing use and suggested need for ultrasonography in labor and delivery rooms. The instrumental progress made in residency teaching of ultrasonography was primarily in the domain of obstetrics.[12] In the imaging literature there is no mention of the gynecologic or emergency room use of this important laboratory tool by residents in obstetrics and gynecology. As noted earlier, the published studies are in the domain of abdominal ultrasonography and were performed by radiologists.

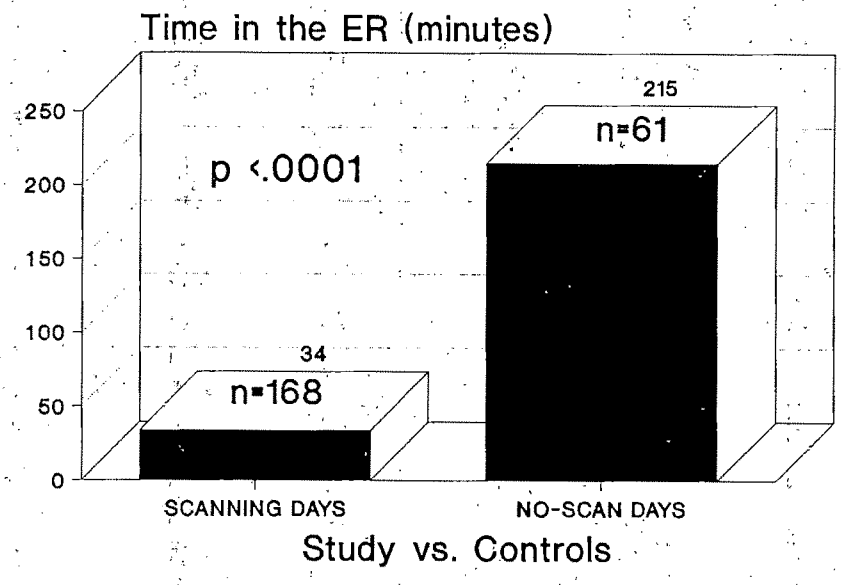

Fig. 5. Time to make the diagnosis.

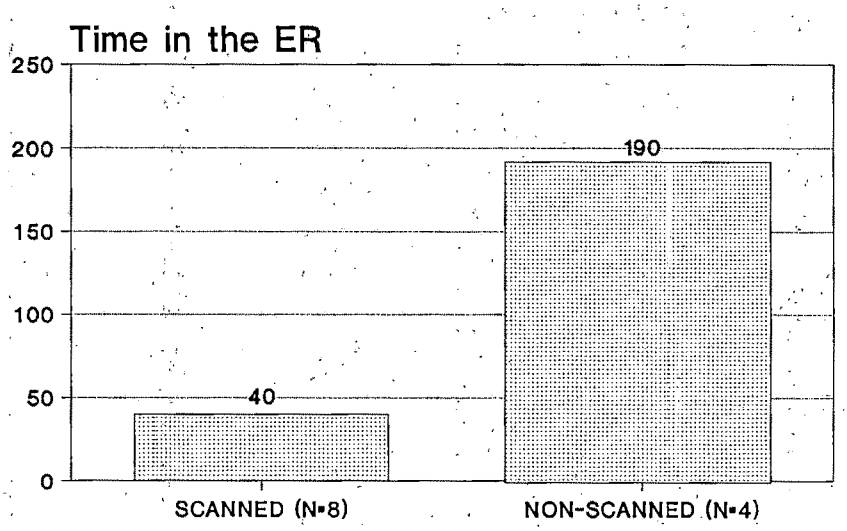

Fig. 6. Average emergency room time (minutes) for ectopic pregnancies.

We reviewed the literature concerning the use of transabdominal ultrasonography in the emergency room, for the management of gynecologic patients. Stabile et al.[3] used high-resolution abdominal sector scanning in the gynecologic emergency room for pregnancy-related diagnoses. In 158 of 624 patients there was no evidence of pregnancy, 60 patients had ectopic pregnancy, and in 406 women the ultrasonographic examination correctly identified intrauterine pregnancy as the cause of vaginal bleeding. Grumbach et al.[4] reported on the emergency room use of computerized tomography and ultrasonography in patients seen in the emergency room with bleeding during pregnancy and other gynecologic problems. Ultrasonography and computerized tomography were considered by these authors as important tools in the workup of many patients treated by the emergency room physician. Shea and Aghababian[5] evaluated the frequency of abdominal and pelvic ultrasonography in the emergency room. Forty-three of 1010 patients who were seen in the emergency room with abdominal or vaginal bleeding required ultrasonography.

It was clear that a study to evaluate the use of transvaginal ultrasonography in the emergency room was needed. The physician seeing obstetrics and gynecology patients in our emergency room is a resident already trained in ultrasonography/ therefore we chose the obstetrics and gynecology resident physician as our model for this study.

The results of our study emphasize several points in the efficacy and diagnosis of gynecologic emergency room illness and the cost of reaching a diagnosis.

First, of the 167 patients who were scanned on scanning days, 83% had pregnancy-related diseases, such as "rule out ectopic" and other problems in pregnancy. On the nonscanning days the diagnoses were similar.

In one third of these cases (44/138 patients) the final diagnosis was aided by a scan completed in ≤5 minutes with ultrasonography. The most important subset of the pregnancy-related problems are the patients with suspected ectopic pregnancy. A closer look at this patient population revealed that only seven of 70 patients with suspected ectopic pregnancy had the condition. The patients in the study group were diagnosed relatively rapidly (40 minutes as opposed to 190 minutes in the control group) as having an ectopic gestation. This evaluation was longer on the nonscanning days because of waiting for a quantitative pregnancy test and an ultrasonography scan, off site and at another time. An additional ectopic gestation was found in a patient with a suspected ovarian cyst during the bimanual examination preceding the scan.

The second important aspect of the study was the statistically significant time difference for arriving at the final diagnosis between the scanned group and the control group. The faster turnover in the emergency room and the shorter time until definitive treatment can be started is an achievement appreciated not only by hospital staff but also by residents themselves who can use the excess time generated. Our initial idea was to measure the efficiency of ultrasonography in the emergency room by looking at the number of unnecessary admissions occurring on nonscanning days. However, one must realize that even on nonscanning days the patients had gotten the necessary laboratory tests and ultrasonography scans at an off-site location. Therefore regardless of the diagnostic route a correct diagnosis was achieved. Comparing the number of admissions in the scanned and nonscanned group would not necessarily reflect the difference in the diagnoses. The same is true if we look at the necessary or unnecessary procedures that occurred. The one area that is indicative of the performance of scans in the emergency room is the time difference between the two groups, that is, the time at which the final diagnosis was reached.

The third and last point is the issue of the missed diagnoses. As with every laboratory tool, the ultrasonography examination also has its misdiagnoses. A total of six missed diagnoses were noted in the scanning group. Three of them concerning abnormal intrauterine pregnancies seem insignificant because they did not jeopardize the immediate treatment given to the patient. Of more concern are the misdiagnosed ectopic pregnancies. None was a bleeding or ruptured tubal ectopic pregnancy. Had that been the case, the free culde-sac fluid would have been recognized at once by the residents who are specially trained for this occurrence. None of these three patients was discharged because they had a positive β-human chorionic gonadotropin test result and there was no intrauterine pregnancy. The suspicion of an ectopic pregnancy was therefore maintained. The correct diagnosis was made during subsequent procedures (curettage and laparoscopy).

Transvaginal ultrasonography contributed valuable information to the diagnostic process in 41% of our study cases by changing the initial diagnosis and bringing about a correct diagnosis.

In summary, the use of ultrasonography performed by experienced obstetrics and gynecology residents was tested. The analysis of the study group and control group showed differences in (1) the speed of the diagnostic process and (2) the accuracy of the diagnosis in favor of the scanned group.

There were six missed diagnoses in the scanned group but no ill effects on the patients. In spite of a few complicated and lengthy scans the residents expressed a high confidence level in operating ultrasonography equipment in the emergency room.

Therefore we conclude that the residents can efficiently use transvaginal ultrasonography in the emergency room. This transvaginal ultrasonography is in addition to the bimanual pelvic examination and should be performed subsequent to the bimanual examination. The emergency room ultrasonography in general, transvaginal ultrasonography in particular, is important because (1) it shortens the time spent in the emergency room, not only for the patients but also for the managing residents, and (2) it contributes to a correct and quick diagnosis in the majority of the patients.

The statement of the American College of Emergency Physicians and the initial report from the American Institute of Ultrasound in Medicine Ad Hoc Committee on Ultrasound in Emergency Medicine clearly states that ". . . it is the responsibility of the ultrasound physicians (Radiology, Cardiology, Obstetrics, etc.) to provide the ultrasound service . . . on a timely 24-hour seven days a week basis. . . ."

For quick and efficient patient care the use of ultrasonography (including a vaginal probe) in the emergency room, operated by the resident on call, should be encouraged.

We thank the resident staff of our department whose collaboration and hard work in generating the data helped bring it all together.

Ultrasonographic dating of pregnancy causes significant errors in Down syndrome risk assessment that may be minimized by use of biparietal diameter–based means

Timothy M. Reynolds, MB, ChB,[a] Michael D. Penney, MD,[b] and Howard Hughes, MSc[b]
Cardiff and Newport, Wales

OBJECTIVES: Gestational dates assessed by ultrasonographic measurement of fetal dimensions are usually quoted in terms of complete weeks because the uncertainty of ultrasonographic measurement is approximately ±7 days. This study examines the effect of ultrasonographic dating on Down syndrome risk assessment.
STUDY DESIGN: The effect of small changes in measured biparietal diameter resulting in a change in estimated gestational week and the benefits of a more precise measure of fetal gestational age (raw biparietal diameter) are examined mathematically.
RESULTS: If maternal serum α-fetoprotein and human chorionic gonadotropin are used to assess Down syndrome risk, risks assessed with ultrasonographically determined dates may be ≤45% too high for fetuses with biparietal diameter at the lowest end of the size band and ≤22% too low with biparietal diameter at the top of the size band. If the results for maternal serum α-fetoprotein, human chorionic gonadotropin, and unconjugated estriol are used, these figures become ≤150% and ≤60%, respectively.
CONCLUSION: If ultrasonography is used to assess gestational age, the raw biparietal diameter and not the estimated week of gestation must be used to derive means for calculation of multiples of the mean.
(AM J OBSTET GYNECOL 1992;166:872-7.)

Key words: Trisomy 21, multivariate risk screening, α-fetoprotein, human chorionic gonadotropin, unconjugated estriol

In the majority of hospitals in the United Kingdom the gestational duration is calculated from the date of last menstrual period (LMP); this date is checked by ultrasonographic measurement of the crown-rump length or biparietal diameter (BPD). In some hospitals the LMP date is used as the "gold standard" and is only altered by the results of the ultrasonographic examination if there is a discrepancy in dates of ≥2 weeks. Other hospitals use the BPD-derived dates as the final arbiter of gestational age. Unfortunately, it is not possible to estimate exact dates from BPD measurements (i.e., the relationship between BPD and true gestational age is continuous, but because of analytic imprecision and biologic variation the technique can only give an accuracy of prediction of ±7 days[1]). Consequently, gestational dates derived from BPD data are invariably

quoted in terms of complete weeks, such that a band of BPD sizes corresponds to a single week of gestational age; this inevitably results in imprecision at the edges of the size band. This loss of precision, however, is not confined to interpretation of BPD measurement because gestational age calculated from LMP is invariably rounded up or down to the nearest whole week. In our laboratory 77% of the samples received for Down syndrome screening are from women who had been ultrasonographically assessed before blood sampling; 90% of these women have gestational age quoted in whole weeks.

We investigated the difference between Down syndrome risks calculated with multiples of the mean for maternal serum α-fetoprotein (AFP) and human chorionic gonadotropin (hCG) levels with means based on BPD-derived gestational age (gestational week) and means based on raw BPD data. We estimated inaccuracies resulting from addition of a third analyte, unconjugated estriol.

Methods and results

The screening data of 4605 women routinely screened for Down syndrome–associated pregnancy between January and November 1990 were examined. After exclusion of 1060 data sets from women with multiple pregnancies, women who had not been scanned, and women whose data sets were incomplete, and exclusion of 523 results from women who had not been scanned on the same day as the blood sample was collected for screening, there were 3022 complete data sets. A complete data set included the mother's age at expected date of delivery, BPD measured outer table to outer table, AFP, and hCG.

Table I shows the size bands used to determine gestational week. Many laboratories receive ultrasonographically derived gestational age as a decimal value (e.g., 16.1, 15.5). These values are derived from a similar size-band table or by calculation with regression parameters for BPD versus dates. Although decimal values appear to be more accurate, they are just as uncertain as other ultrasonographically derived measurements.

Log transformation of AFP and hCG values resulted in normalization of the data, and therefore least-squares regression of log 10 (AFP) and log 10 (hCG) against raw BPD or gestational week was performed to derive means for AFP or hCG relative to BPD or gestational week. This method generates "regressed mean" values because all the patient results are used to derive the regression parameters. Previous workers[2] have derived "regressed medians" by determining the median for each week individually and then weighted least-squares regression. Medians for weeks 13 through 27 were used. For example, at 16 weeks there were 122 patients; to calculate the regression, the value for the 16-week median was entered into the least-squares regression 122 times. For many of the weeks used, medians were based on <10 patient results. The regressed means are statistically valid because log transformation resulted in a gaussian distribution for the data. Furthermore, only data for weeks 14 through 20 were used to generate regression parameters; regressed means were only considered valid for weeks 15 through 19 (minimum data set was for 15 weeks, $n = 228$). The regression parameters are shown in Table II.

	Gestational week		*BPD (mm)*	
Coefficient	*AFP*	*hCG*	*AFP*	*hCG*
A	0.7495	2.2797	0.9758	2.0076
B	0.047339	−0.057547	0.01452	−0.017716
r	0.2252	−0.2067	0.2354	−0.2170

Formula for regressed mean, $10^{(A + B \times)}$. x, Week or BPD size; A and B, regression coefficients; r, sample correlation coefficient.

With these regression parameters it is possible to calculate regressed means for BPD-derived, gestational week–based, and BPD-based gestational dating methods (e.g., for a 16-week pregnancy, the regressed mean for AFP is $10^{[0.7495 + (16 \times 0.047389)]} = 32.1$ kU/L). These means are then used to calculate the multiples of the mean (usually given as multiples of the median), which are required for the multivariate method of calculation of Down syndrome risk factors.[3] Regressed means for gestational weeks 15 through 18 and for extremes of BPD size bands are shown in Table III. The BPD size band extremes are the points on a BPD size band at which a minimal change in measured BPD (0.1 mm) is sufficient to change the estimated week of gestation (e.g., 34.0 mm corresponds to 15 weeks and 34.1 mm to 16 weeks). There was no significant difference between means derived for gestational week and locally derived medians.

To examine the effect on screening of varying the

method of calculating the mean, a series of values were tested with the means shown in Table III. These were derived from gestational week or extremes of BPD size band with the regression parameters in Table II. AFP and hCG values were chosen such that with week-based means the multiples of the means would be 0.5, 1.5, and 2.5, assuming the gestational week was week 16. With these values, multiples of the means were calculated with BPD-derived means assuming BPD was at each extreme of the size band. These values are shown in Table IV. The multiples of the means were applied to the multivariate screening algorithm[3] with parameters previously described.[2] It should be noted that these parameters were derived from LMP-dated pregnancies; however, because the multiples of the median for both Down syndrome and normal pregnancies remain constant throughout the screening time window, it is unlikely that different dating methods will significantly alter the differential between normal and affected pregnancies. Therefore risk factors calculated with these parameters should be representative. The Down syndrome risk factors calculated with these multiples of the means and the percentage differences between the gestational week–based multiples of the mean Down syndrome risk factor and the BPD-based multiples of the mean Down syndrome risk factors are shown in Table V.

Finally, the effect of a 0.1 mm change in BPD, which results in a change from one size band to another, was examined. Risks were calculated with week-based means to calculate multiples of the means for values corresponding to 0.5, 1.5, and 2.5 multiples of the means for BPD equal to 38 and 38.1 mm. These multiples of the means are shown in Table VI; the week-based multiples of the mean Down syndrome risk factor and percentage difference between risks at gestational weeks 16 and 17 are shown in Table VII.

Comment

Biochemical screening for Down syndrome in pregnancy has only recently become possible. The first steps were reported in 1984 when the association between low maternal serum AFP and Down syndrome was reported.[4, 5] Later the inclusion of maternal age[6] introduced the concept of risk screening with a cut-off designed to select patients requiring amniocentesis. This technique was taken up rapidly, and by 1988 approximately 1 million pregnancies in the United States were

screened annually.[7] This screen allowed detection of only 25% of affected fetuses in women aged <35 years.[8] At this time it was discovered that other serum analytes were also affected by the presence of a Down syndrome affected–fetus (hCG,[9] unconjugated estriol[10, 11]). The addition of these analytes to the screening method improved the detection rate to 63%.[12] It is thus clear that the addition of the extra analytes significantly improved the screen; however, it must be emphasized that this test is still in its infancy and its precision may be further improved.

One problem with the screen is interpretation of results partly because there are a number of methods for calculation of risk (discriminant function analysis,[13] AFP/hCG ratio,[14] multivariate gaussian distribution function[2, 3]) and partly because risk prediction is a new concept for many clinicians. Furthermore, the concentrations of the analytes vary throughout pregnancy; some method of assessing gestational age must be used to allow standardization of the measured concentrations. The original description of Down syndrome screening with the multivariate method included gestational dating by LMP.[2] This method is problematic because of poor recall of LMP date and variations in cycle length. Similarly, estimation of gestational age by ultrasonography is sometimes inaccurate because of variations in fetal growth rate and poor recall of LMP date, both of which render collection of accurate data relating BPD to gestational age impossible. This inability to accurately date a pregnancy by LMP or BPD

Multiples of the mean used for weeks 16 and 17 are those in Table VI. All multiples of the mean are BPD-based. Risk factors shown are 1 : n. Risk factors are shown to six significant figures to emphasize differences. Risks generated in screening would not be reported to this accuracy.

may partially explain previous reports that BPD dating does not improve screening efficiency in AFP screening for Down syndrome[15] and that combined LMP and BPD dating does offer some improvement in neural tube defect screening.[16]

Further complications include numerous protocols for relating BPD to gestational week, differences in the fetal growth rate between races, and differences in methods of measuring BPD (inner to outer table, outer to outer table).[15, 17-22]

Our investigation avoided many of the above pitfalls because a single BPD/age conversion protocol was used, all measurements of BPD were performed by the same method (outer to outer table), and the population of the county Gwent is mostly racially homogeneous.

The results in Table V clearly demonstrate that if a risk is calculated with the two variables (AFP and hCG) and if gestational week is estimated by ultrasonographic examination the risk generated may be significantly at variance with the risk factor calculated with BPD-derived means. Thus if the fetal head is at the lowest end of the size band it is possible that the risk calculated is too high by ≤45%, which may result in an unnecessary referral for amniocentesis. Similarly if the fetal head is at the top of the size band the risk calculated may be up to 22% too low, resulting in a failure to refer for amniocentesis.

Table VII provides further evidence that basing multiples of the mean calculation on gestational week derived from ultrasonography is not effective. A change in BPD of only 0.1 mm, resulting in a change of size band, is sufficient to change the calculated risk by 40%.

These results only cover the effect of two screening variables. The effect of three screening variables (i.e., including unconjugated estriol) can be estimated by conservatively assuming a ±5% variation between the unconjugated estriol week–based and BPD-based means and applying the resulting values to the risk calculation algorithm as before. This results in an estimate that, with three variables and gestational week–based means, the error may be 55% to 150% for fetal head sizes at the lowest end of the size band and 25% to 60% at the top of the size band (data not shown).

Furthermore, these estimates of errors in risk do not take analytic errors into account. The error for ultrasonographic measurement of BPD was reported as approximately 1.5 mm in 1974[23] which, at a BPD of 34 mm, corresponds to 4.5%. Comparative studies in 1984 gave an absolute error of 1.7 mm for an object 51 mm in diameter (3.3%).[24] Newer ultrasonography machines may be more accurate, but because the above studies did not include observer errors, this is unlikely. Likewise in our laboratory, for AFP at a concentration corresponding to 0.6 multiples of the mean for week 16, the coefficient of variation is 7.8%; for hCG the coefficient of variation is 9.9% at a concentration corresponding to 1 multiple of the mean.

The unavoidable errors from analytic variation can only worsen the situation. Deliberate loss of precision by converting a relatively precise measurement of gestation (BPD) to an imprecise measure (gestational week) can and should be avoided. We therefore believe that if gestational dates are to be checked by ultrasonography, means based on BPD should be used instead of medians based on gestational week derived from BPD. To implement this method of screening will necessitate the coordination of ultrasonographic examination and biochemical sampling so that they are performed on the same day.

Finally, it should be remembered that genetically ab-

normal fetuses may have abnormally small or large heads. Obviously if the defect is gross it will be recognized and appropriate action will be taken; however, minor abnormalities may not be detected. This could affect gestational staging either by BPD alone or by BPD-derived gestational week. To minimize this effect, the ratio between BPD and another ultrasonographic measurement may be effective. The BPD/femur length ratio has already been shown by a number of investigators to be abnormal in Down syndrome. This ratio also shows a trend through gestation that may be standardized for use with BPD.[25]

Because the imprecision of the screen increases exponentially as more analytes are included, the effect of replacing one of the biochemical variables by the ultrasonographic measurement should be examined in addition to the effect of BPD-based means for calculation of multiples of the means. The most likely candidate for exclusion would be unconjugated estriol because, although its decreased concentration in Down syndrome–affected pregnancies is similar to the decrease in AFP, AFP has a second role in screening for neural tube defects. Unfortunately, we do not have access to a sufficiently large population to test the effect on screening efficiency of BPD-based means, but we believe that there is likely to be an improved detection rate and probably a significant decrease in the false-positive rate if BPD-derived means are used.

Infarction of the uterus from subacute incomplete inversion

Mary S. Romo, MD,[a] David A. Grimes, MD,[a] and Philip O. Strassle, MD[b]
Los Angeles, California

A patient with subacute incomplete uterine inversion was transferred to our hospital when the diagnosis was made 5 days after vaginal delivery. Intravenous injection of sodium fluorescein dye identified a clear demarcation between viable and necrotic myometrium. The superior aspect of the uterus was infarcted; therefore a hysterectomy was performed. (Am J Obstet Gynecol 1992;166:878-9.)

Key words: Uterus, inversion, infarction, fluorescein

Subacute incomplete inversion of the uterus is a rare obstetric complication. We cared for such a patient, in whom the intraoperative administration of intravenous sodium fluorescein dye confirmed the diagnosis of infarction of the uterus, which led us to perform a hysterectomy.

Case report

A 28-year-old woman, gravida 2, para 1, abortus 1, had a vaginal delivery at term complicated by postpartum hemorrhage. She received three units of packed red blood cells because of the hemorrhage, thought to be a result of uterine atony. She was started on a regimen of oral methylergonovine maleate. On the second day after delivery, a fever of 38.3° C and a leukocytosis of 26,200 white blood cells per milliliter developed. She was started on a regimen of intravenous ampicillin.

Abdominal pain persisted, and 1 day later she underwent a pelvic ultrasonographic examination which revealed a 20 × 13 × 13 cm uterus with endometrial fluid "consistent with endometritis." Pain and vaginal bleeding continued, and 2 days later the patient had a pelvic examination done. The fundus could not be palpated abdominally, and the patient was transferred to our hospital.

On admission vital signs were normal and temperature was 37.6° C. Pelvic examination revealed a dusky mass protruding through the cervix and extending to within 3 cm of the introitus. Hematocrit was 32%. She was given intravenous clindamycin and gentamicin. In the operating room, in spite of the administration of halogenated anesthetic agents and intravenous magnesium sulfate and terbutaline, we could not reduce the inversion by a vaginal approach.

A vertical abdominal incision was then made, and we found the fundus to be inverted with both tubes and ovaries drawn into an inversion ring (Fig. 1). The tight ring prevented replacement of the uterus in spite of the use of traction sutures in the uterus (Huntington procedure)[1] combined with elevation of the fundus with the surgeon's hand in the vagina. A vertical incision of the anterior surface of the uterus enabled us to restore the uterus to its normal position, yet the superior aspect of the uterus felt soft and appeared dusky. Suspecting infarction of the uterus from entrapment in the inversion ring, we injected 700 mg of sodium fluorescein dye (10 mg/kg) intravenously and illuminated the uterus with a fluorescent lamp. A clear line of demarcation between viable and necrotic myometrium was evident. Because of the extent of the injury and the established infection of the necrotic uterus, we performed a hysterectomy. The patient's postoperative course was smooth, and she went home 5 days later.

The pathology report on the uterus revealed the lower uterine segment to be firm, tan, and normal for the postpartum state. The transition between viable and dead tissue was distinct. The necrotic area involved the posterior wall of the uterus more than the anterior wall. Microscopic examination indicated extensive coagulative necrosis of the myometrium and acute endometritis and myometritis with occasional bacterial colonies. There were also ischemic changes in areas bordering the regions of coagulative necrosis.

Comment

Cases of inversion of the uterus are classified both by timing in relation to delivery and by extent of the anatomic defect. Cases are termed acute within 24 hours of delivery, subacute from 24 hours to 4 weeks after delivery, and chronic after 4 weeks. With incomplete inversion the fundus extends to the level of the cervix (first degree) or below the cervix but not to the introitus (second degree). In contrast, with complete inversion the fundus extends either to the introitus (third degree) or beyond the introitus, with the vagina inverted as well (fourth degree).[1] In a 9-year review of uterine inversion in our hospital, encompassing >100,000 deliveries, the incidence of inversion was four per 10,000 deliveries. Of these, <4% were subacute, with the remainder being acute. On the other

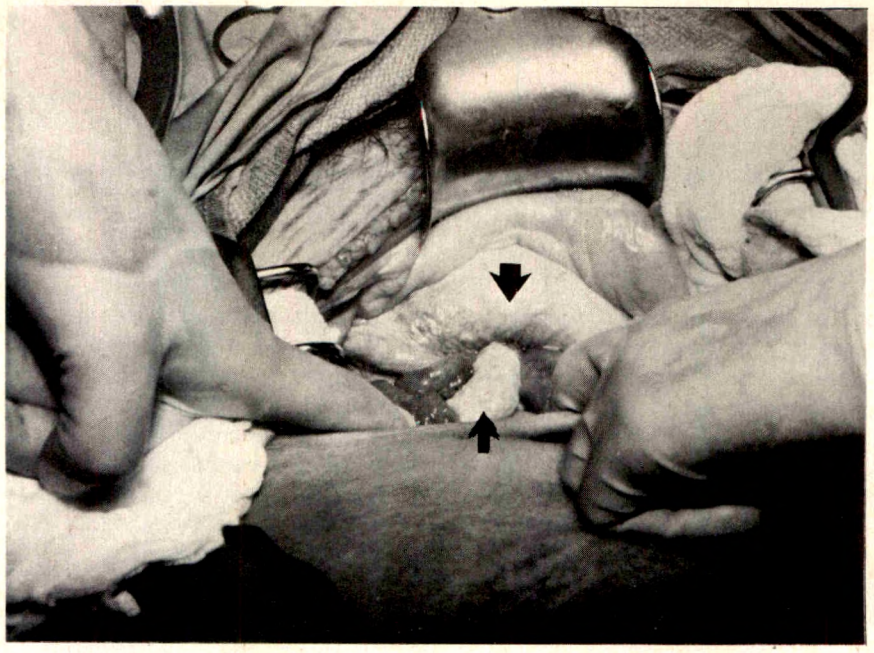

Fig. 1. View of superior aspect of uterus at laparotomy, showing inversion ring *(large arrow)* with both fallopian tubes and one ovary *(small arrow)* drawn into ring. One ovary was caudad to inversion ring.

hand, second-degree incomplete inversion was the most frequent extent of inversion, as occurred in this case.

We chose an anterior hysterotomy incision because of ease of exposure. In contrast, the traditional approach to this problem has been an incision on the posterior surface of the uterus (Haultain procedure),[2] first described at the turn of the century. In addition, vaginal hysterotomy procedures, such as the Spinelli and Küstner operations, have been used with success.[2]

Infarction as a complication of uterine inversion has not been described in recent case-series reports. However, death from gangrene of the uterus has been reported decades ago.[3] In addition, one case of intestinal strangulation, presumably from entrapment in the inversion ring, has been described. The infrequency of infarction as a complication of inversion may reflect the low incidence of inversion, rapid diagnosis, prompt treatment, or a combination of these.

Use of intravenous sodium fluorescein dye confirmed the diagnosis of necrosis of the uterus. Since the early 1940s this technique has been used to determine circulatory failure, ischemia, and necrosis. With an intravenous dose of 10 to 15 mg/kg, all perfused tissues will exhibit fluorescence within 5 to 7 minutes. The technique has been used clinically to determine the viability of bowel during gastrointestinal operations and to guide the extent of excision of infected soft tissue. The approach is simple, safe, and inexpensive; in this case it allowed a definitive diagnosis of infarction to be made during the initial laparotomy, thus avoiding the need for a later hysterectomy.

The primary application of three-dimensional ultrasonography in obstetrics

Hong-Chang Kuo, MD, Fong-Ming Chang, MD, Chun-Hsein Wu, MD, Bor-Lin Yao, MD, and Chi-Hong Liu, MD

Tainan, Taiwan

To date, no report of three-dimensional ultrasonography in obstetrics has been available in the literature. In this study we describe the primary experience with three-dimensional ultrasonography for the prenatal evaluation of nine fetuses between 21 and 33 weeks of gestation. We found that it provides more information for clinical diagnosis than the traditional two-dimensional ultrasonography. The following advantages are notable: (1) the anatomic area of interest can be located first with the conventional real-time two-dimensional mode, then switched to reveal three-dimensional images, instantly; (2) three images are exhibited concurrently; (3) each of the three images can be arrayed separately and scrolled to search for the area of interest within the scanned volume; (4) the three-dimensional ultrasonography can be equipped with Doppler color flow mapping for the study of the fetal cardiovascular system. In conclusion, we believe that three-dimensional ultrasonography can greatly strengthen diagnostic potential, which deserves obstetricians' attention. (Am J Obstet Gynecol 1992;166:880-6.)

Key words: Three-dimensional, ultrasonography, obstetrics

The application of real-time ultrasonography has played a very important role in modern obstetrics. Traditional real-time two-dimensional ultrasonography is usually position dependent and gives only a linear observation of the structures of the fetuses. However, there are several disadvantages, as a result of oligohydramnios, movable status of the fetus, acoustic shadow caused by skeleton, or trunk and extremities of the fetus that are improperly positioned for observation. It is difficult to scan the structures of the fetus in detail, especially complex lesions of the central nervous and cardiovascular systems.[1] With the recent introduction of three-dimensional ultrasonography, in which three continual different planes are displayed simultaneously, we have attempted to resolve the disadvantages of the traditional two-dimensional echo to get as much accurate information as possible. In this study nine fetuses were examined systemically with both two-dimensional and three-dimensional ultrasonography, including a fetus with hydronephrosis and hydroureter.

Material and methods

Nine fetuses between 21 and 33 weeks of gestation were studied. Before three-dimensional ultrasonographic examination (Kretz Combison 330, 3.5 MHz, Zipf, Austria), each fetus underwent the traditional two-dimensional examination (Aloka 650, 3.5 MHz, Tokyo) in which the following parameters were examined: biparietal diameter, orbital diameter, interorbital distance, chest circumference, abdominal circumference, and femur length. Further examination of the fetal anatomy was done in detail for detection of malformation of the central nervous, cardiovascular, gastrointestinal, genitourinary, and skeletomuscular systems. We paid special attention to the fetal head and heart with three-dimensional ultrasonography for analysis of these complex structures in all spatial planes.

According to the manufacturer's manual, three-dimensional ultrasonography is characterized by a special transducer performing two-dimensional scan, sweeping slowly across an arc of 90-60 degrees. The transducer produces continual two-dimensional images a millimeter apart, across an arc of 90-60 degrees. The entire scanned volume can be stored in a memory system, a procedure that takes about 3.5 seconds. We can view the scanned volume simultaneously in three different planes that are perpendicular to each other; these planes are the B plane, C plane, and O plane, representing the longitudinal, transverse, and horizontal sections (Fig. 1). Within the scanned volume, images confined in the three planes can be moved millimeter by millimeter, and their relative positions are indicated with reference lines at the other two planes on the monitor. Any desired section can be displayed, within the scanned volume, by three position controls. The

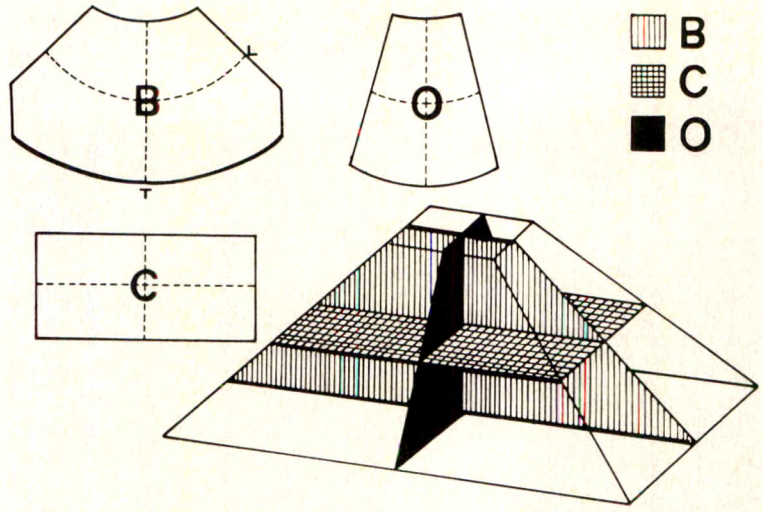

Fig. 1. Within scanned volume, three different planes, *B*, *O*, and *C* planes, perpendicular to each other are illustrated. These planes are consistent in orientation in all subsequent illustrations. T line indicates transverse line of *B* plane. L line is longitudinal line of *B* plane.

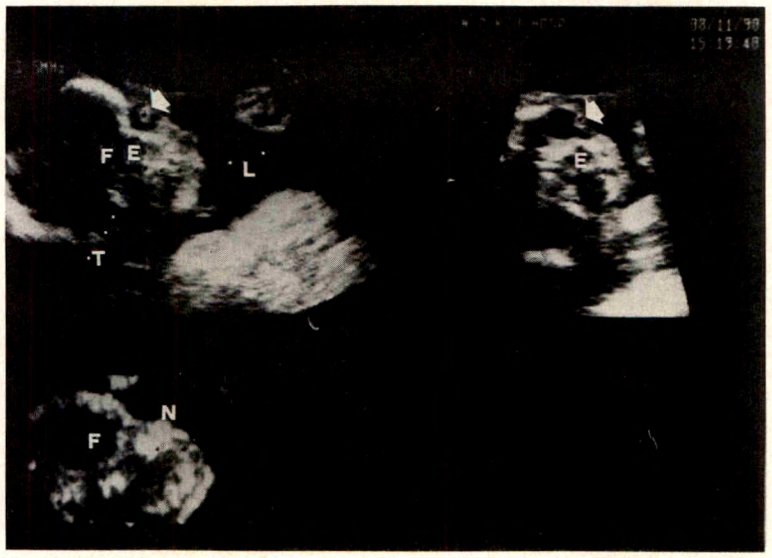

Fig. 2. Fetal face demonstrated well in B plane. Bilateral orbital cavities in O plane were visualized as T line *(T)* was scrolled to midorbital position. Midsagittal view of fetal head in C plane was displayed while L line *(L)* was moved to midface position. *E*, Ethmoid sinuses; *F*, frontal lobe; *N*, nose; *arrow*, lens.

scanned volume may consist of 30 to 60 sections of two-dimensional images about a millimeter apart, depending on the scan angle and depth in one scanned volume. All of these sectional images are presented independently of each other; thus this is a promising technique to analyze the complex anatomy of the fetal head and cardiovascular system.

The three-dimensional ultrasonography is displayed with a 60- or 90-degree sector. The maximum penetration depth of the VWP3.5 3D-Voluson transducer is 210 mm at a transmitting-receiving frequency of 3.5 MHz. The frame rates are 5 to 15 frames/sec at a 90-degree scan angle and 5 to 20 frames/sec at a 60-degree scan angle, depending on the width of sector display and the length and pulse repetition frequency. The power output (spatial-peak temporal average) for three-dimensional ultrasonography is 51 mW/cm^2 measured in water.

Results

With the introduction of three-dimensional ultrasonography, it is feasible to view images of successive fetal anatomic divisions in three different planes simultaneously. Therefore the three-dimensional technology

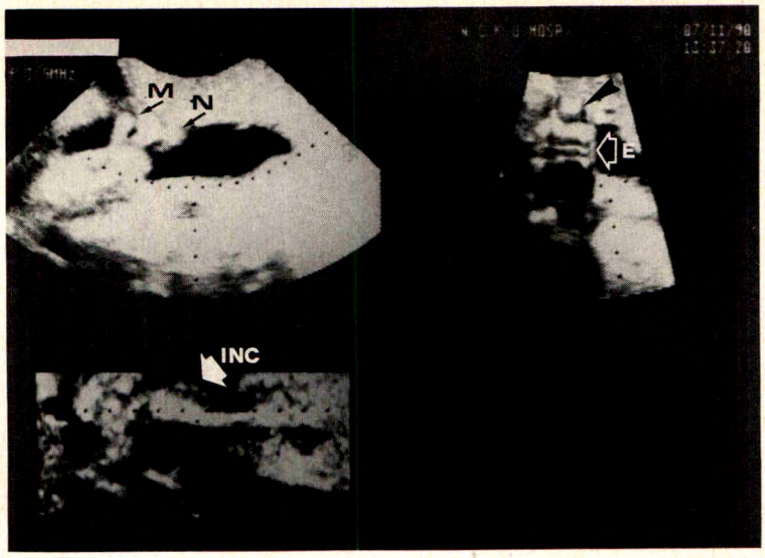

Fig. 3. Coronary view of fetal nose *(N)* and mouth *(M)* seen in B plane. Although orbital cavity was invisible, ethmoid sinuses *(E)* could be seen by scrolling T line to midorbital level. Inferior nasal concha *(INC)* was shown in C plane. *Arrowhead*, Eye.

greatly increases diagnostic potential in obstetrics, with the benefit of its ultimate three-dimensional demonstration of the complicated structures of the fetus. In our study only one fetus with hydronephrosis was detected. The other eight fetuses appeared grossly normal, and serial evaluations of the fetal organs were shown as successive views with the 3.5 MHz transducer.

Fetal head

Fetal face. The fetal face was easily imaged with the two-dimensional real-time mode (Fig. 2, B plane). The bilateral orbital cavities were displayed in the O plane with clear margins by scrolling the transverse line (T line) of the B plane to the midorbital position. Of interest is the ease in observing the midsagittal view of the fetal head, whereas the longitudinal line (L line) of the B plane was moved to the midface position (Fig. 2, C plane). The outlines of the fetal nose and upper and lower lips, as well as the frontal lobe, parietal lobe, occipital lobe, and petrous region, were shown. Similar diagnostic excellence is implied by Fig. 3, in which we cannot see the orbital cavities and ethmoid sinuses in the B plane, yet they do appear in the O plane, through storage of the scan geometry. Because of problems with vertical resolution, the oral cavity and tongue cannot be seen as clearly as the inferior nasal concha and inferior meatus in the C plane (Fig. 3).

Bilateral parietal plane. The axis scan over the bilateral parietal level reveals the complex structures in this volume, including the frontal lobe, temporal lobe, cerebral falx, cavum of septum pellucidum, third ventricle, thalamus, and hippocampus[2] (Fig. 4). Of interest is the demonstration of the corpus callosum in the C plane and the trigone of the lateral ventricle in the O plane, both of which are not always visualized because of a position of the fetal head that is unattainable by conventional two-dimensional echo.

Cerebellum and cervical vertebrae. The coronary section was transmitted obliquely through the fetal head to show the parietal lobe, ambiens, cerebral peduncle, tentorium cerebelli, cerebellum (cerebellar hemisphere and vermis), medulla oblongata, and then the cervical spine from the upper to the lower part of this plane. The cisterna cerebellomedullaris and the sagittal section of the atlantooccipital joint could be displayed in detail, separately.

Cardiovascular system. With the development of high-resolution ultrasonography, we can visualize the fetal heart as early as possible. However, cardiac lesions, such as small septal defects, valvular anomalies, and abnormalities of pulmonary venous return, are usually position dependent with varying presentations of the fetus and are difficult to detect with the use of a two-dimensional scan.[1, 3] We use three-dimensional ultrasonography to survey the complex structures in different planes. We believe that three-dimensional ultrasonography can offer information beyond that with the conventional two-dimensional echo in fetal echocardiography. In our clinical practice we displayed several views of importance in fetal echocardiography, such as the four-chamber view, five-chamber view, and several axis views of the great vessels, and then interpreted these views in different planes for further analysis.

Four-chamber view. In this view the four cardiac chambers, atrial and ventricular septa, foramen ovale, and pulmonary vein are demonstrated as usual. We scrolled the T line to the cross section of the thoracic descending

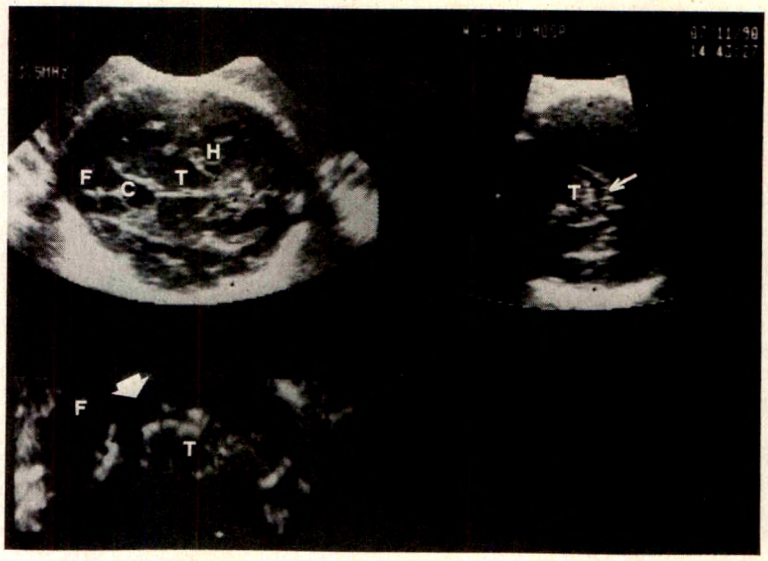

Fig. 4. Axial section at bilateral parietal level revealed frontal lobe *(F)*, cavum septum pellucidum *(C)*, thalamus *(T)*, and hippocampus *(H)* in B plane. Trigone of lateral ventricle *(small arrow)* and corpus callosum *(large arrow)* are shown in O plane and C plane, respectively.

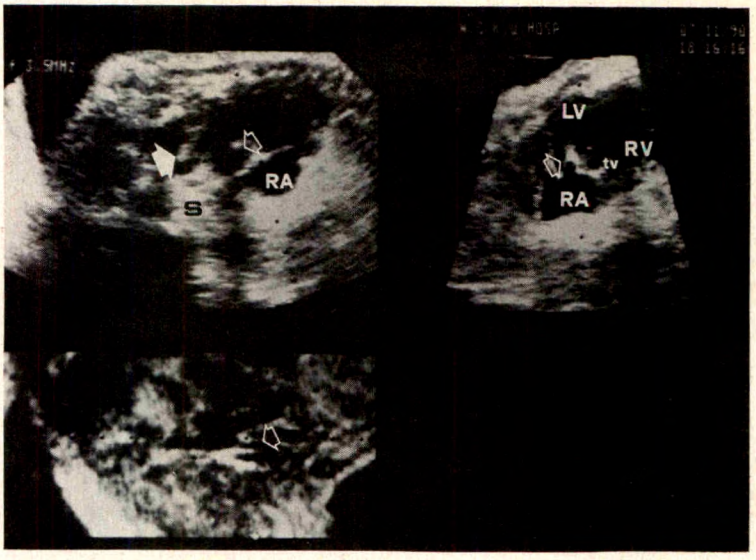

Fig. 5. With slight fetal cephalic tilt of transducer from apical plane, five-chamber view was revealed. Coronary sections of aortic valve *(white halo arrow)* and pulmonary valve *(white arrows)* are indicated. Individual sections of aortic valve were well displayed in O plane and C plane, respectively. *S*, Spine; *tv*, tricuspid valve; *RA*, right atrium; *RV*, right ventricle; *LV*, left ventricle.

aorta; then the long-axis views of the thoracic descending aorta, the superior vena cava, and the pulmonary vein entering the left atrium were demonstrated. The short axis of the ventricles was found by scrolling the L line to this level.

Five-chamber view. With a slight fetal cephalic tilt of the transducer from the plane of the apical view, the ascending aorta constructs the fifth chamber between the right and left atria (Fig. 5, *B-plane*). The coronary section of the cusps of the pulmonary valve and aortic valve could be displayed as the T line was moved to the outlet level of the aorta and pulmonary trunk. The well-shaped aortic valve correlated with the right atrium and right ventricle; the left ventricle was demonstrated in the same B plane at a different location of the T line (Fig. 5, O plane). A similar effect of varying positions of the C plane revealed the longitudinal section of the aortic valves in Fig. 5.

Short-axis–great vessel view. It is essential to interpret the complicated relationship among the great vessels.

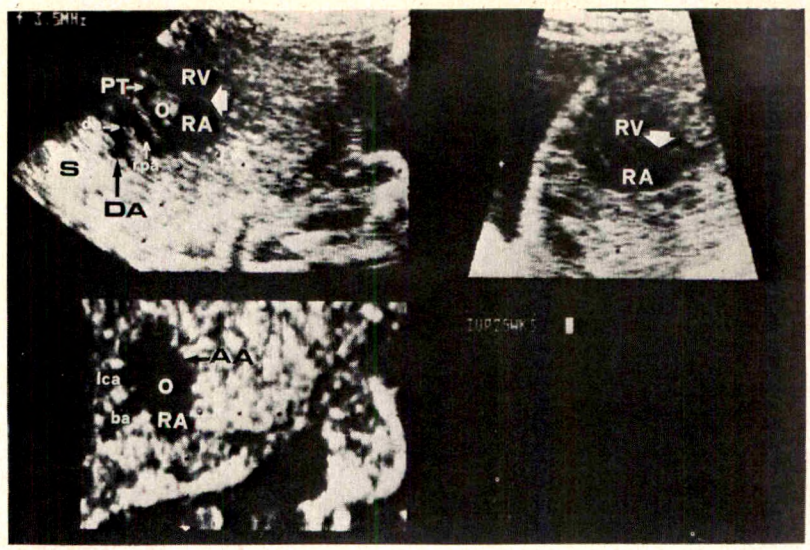

Fig. 6. In this short-axis–great vessel view, right atrium *(RA)*, right ventricle *(RV)*, tricuspid valve *(large white arrow)*, pulmonary trunk *(PT)*, ductus arteriosus *(da)*, and right pulmonary artery *(rpa)* were followed in small counterclockwise rotation (B plane). We can see ductus arteriosus joining descending aorta anterior to spine *(S)*. Longitudinal section of right atrium, right ventricle, and tricuspid valve is shown in O plane. More complicated anatomy of ascending aorta *(AA)* and aortic arch with right atrium is revealed in C plane. *O*, Aortic valve; *ba*, brachiocephalic artery; *lca*, left common carotid artery.

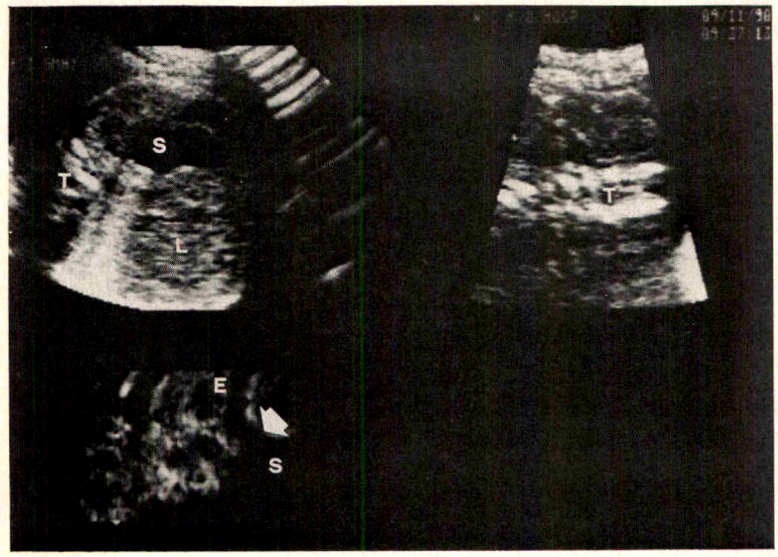

Fig. 7. Transverse section of stomach and liver is displayed in B plane. Well-shaped esophageal-gastric junction *(white arrow)* was unexpectedly demonstrated in C plane. *E*, Esophagus; *L*, liver; *S*, stomach; *T*, spine.

This view shows the right atrium, right ventricle, tricuspid valve, pulmonary valve, main pulmonary artery, ductus arteriosus, and right pulmonary artery arranged in a small counterclockwise rotation (Fig. 6, B plane).[3] The ductus arteriosus enters the descending aorta anterior to the spine. The tricuspid valve was demonstrated well in the O plane. The complex relationship among these greater vessels, including the ascending aorta, left common carotid artery, and brachiocephalic artery, and the aortic valve could be well demonstrated in the C plane.

Umbilical vein and gallbladder. As the ultrasonographic beam transected the fetal abdomen at the bifurcation of the umbilical vein, we could not see the

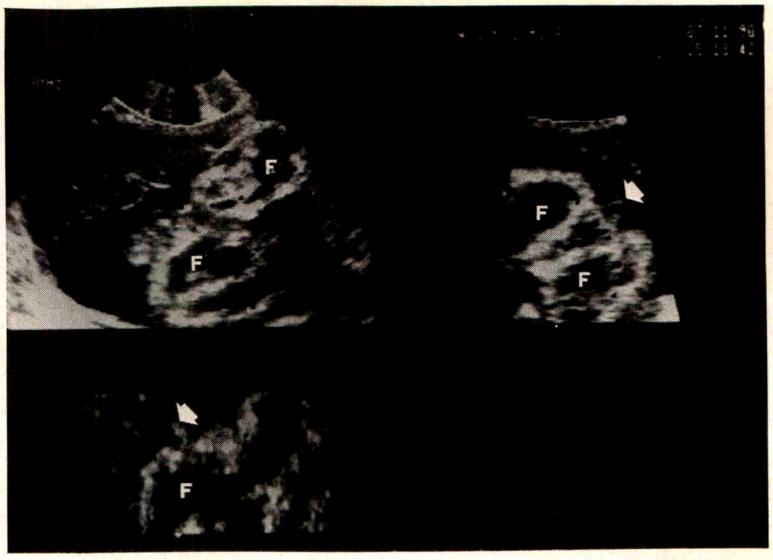

Fig. 8. External genitalia of male fetus could not be identified clearly in B plane, yet we could correctly ascertain male penis *(white arrow)* in both O and C planes. *F*, Femur.

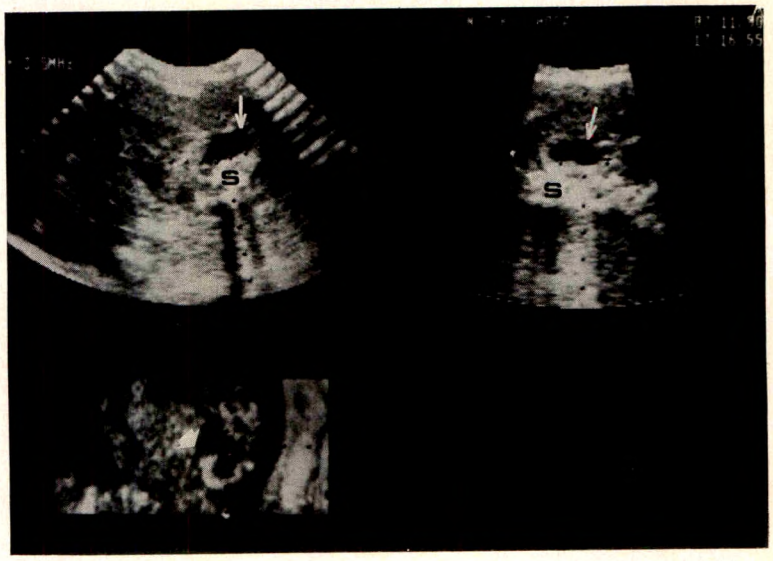

Fig. 9. Hydronephrosis was well demonstrated in three planes. We could see sagittal section of hydroureter *(large white arrow)* in C plane. *S*, Spine.

gallbladder. However, it was visible in the coronary section within the scanned volume.

Esophageal-gastric junction and pylorus. With the fetus lying in a vertex presentation, the B plane displayed the liver, spleen, and cross section of stomach (Fig. 7). Within the scanned volume, the well-shaped esophageal-gastric junction was unexpectedly shown (Fig. 7, C plane). In another case the pylorus was also revealed. In our experience it is uncommon to observe the esophageal-gastric junction and pylorus on the traditional two-dimensional scan. Therefore early prenatal diagnosis of congenital anomalies of the fluid-filled gastrointestinal system will be possible on three-dimensional scan; such diagnosis is difficult after birth because of the poor resolution of the ultrasonographic beam in showing the air-filled organs.

Genitourinary system. Investigation of the genitourinary system has been possible by traditional two-dimensional ultrasonography, yet it is difficult to observe the pelvic-ureter junction and ureterovesical junction except in the presence of hydronephrosis and hydroureter. Three-dimensional ultrasonography allows us to see these fine structures as usual.

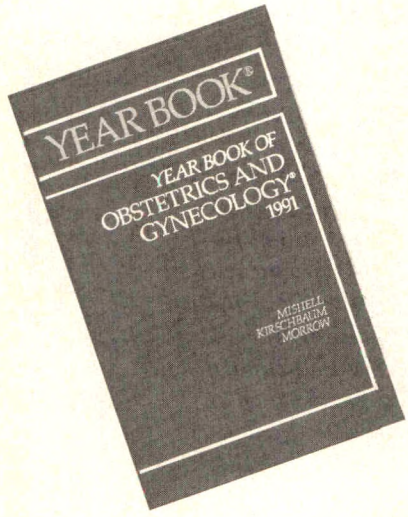
It is not always easy to correctly identify the external

genitalia of the fetus because of improper position of the fetus or ambiguity caused by the poor development of exernal genitalia or confusion with umbilical cord. It is easy to resolve this problem with more confidence with three-dimensional interpretation (Fig. 8).

In our study only one case of a fetal anomaly was detected. A 30-year-old woman, gravida 1, visited our obstetric clinic for a routine prenatal examination at 21 weeks of gestation. Ultrasonographic examination demonstrated an intrauterine pregnancy with a single, live fetus in cephalic presentation with normal amniotic fluid volume. A conventional high-resolution, real-time scanner with a 3.5 MHz transducer revealed hydronephrosis and hydroureter of unknown origin. The three-dimensional ultrasonography was performed 2 weeks later, and we could view clearly the anatomic correlation between the kidney, pelvis, and ureter with three-dimensional evaluation (Fig. 9).

Comment

From our initial experience with three-dimensional ultrasonography in obstetrics, we believe that it could become a very important diagnostic tool for the prenatal diagnosis of fetal anomalies for the following reasons:



1. The anatomic area of interest is located first by using the conventional real-time two-dimensional mode, followed by three-dimensional images.
2. Three images, the B, C, and O planes, are exhibited concurrently. The C plane is perpendicular to the angle of propagation of the ultrasonographic beam, which is inaccessible by conventional techniques. In our study the corpus callosum, the inferior nasal concha, and the longitudinal section of the aortic valve were demonstrated well in this special plane.
3. All three images can be arrayed separately from each other. This technique provides analysis of structures in different spatial planes.
4. The best potential advantage of three-dimensional ultrasonography is that it can be equipped with Doppler color flow mapping for the further study of pathophysiologic characteristics of the fetal cardiovascular system.[1]

Congenital anomaly of the fetus has become the leading cause of neonatal death.[4] It is well known that accurate early prenatal diagnosis of malformation may improve fetal outcome. Nevertheless, there are many blind points or unattainable planes in the complex anatomy of the fetus. Therefore it is difficult to make the correct interpretation on conventional two-dimensional scan. It is our opinion that the adjunctive use of a three-dimensional ultrasonographic imaging system with the normal real-time two-dimensional mode can greatly increase diagnostic accuracy in obstetrics. It suits the need for further analysis of the complex structures of the fetus, especially when an anomaly of the central nervous or cardiovascular system is suspected. In conclusion, we believe that three-dimensional ultrasonography can greatly enhance diagnostic potential, which deserves the attention of obstetricians.

Modern medicine's answer to normal memory loss.

A lively and authoritative review of the year's best journal literature.

Let's face it. Remembering everything from the hundreds of articles you read is a herculean task. You're bound to forget a few important details. It's normal. It's healthy. But with a subscription to the *Year Book of Obstetrics and Gynecology*, it's also unnecessary.

Each year, the *Year Book of Obstetrics and Gynecology* brings you the most important articles relating to obstetrics and gynecology. The articles, chosen by our distinguished editors, are abstracted into concise one and two page summaries for quick and efficient reading. Nearly every article is accompanied by personal commentary from the editors discussing its significance to your daily practice.

The *Year Book of Obstetrics and Gynecology* — it's the best way to remember what you shouldn't forget.

❑ **Yes! I want an overview of the year's most important journal literature.**

Please send my **30-day FREE examination** copy of the *1991 Year Book of Obstetrics and Gynecology* (22118) by Daniel R. Mishell, Jr. If I decide to keep the book I'll pay $57.95 plus shipping and handling.

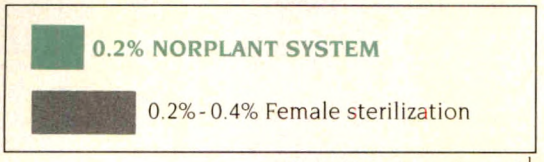
NORPLANT® SYSTEM

levonorgestrel implants



Six reasons why you can feel comfortable recommending it to your patients

Effectiveness comparable to tubal ligation

Although no contraceptive is 100% effective, the NORPLANT SYSTEM is one of the most effective forms of birth control ever developed. The average annual gross pregnancy rate over a five-year period is less than 1%.

Lowest expected and typical failure rates with NORPLANT SYSTEM vs. sterilization during first-year use[1]

Adapted from Trussell J, et al.[1]

Long-term convenience... estrogen-free

NORPLANT SYSTEM, a progestin-only contraceptive, is an excellent option for women desiring a long-term method. Its effectiveness lasts for five years and is not dependent on compliance.

Reversible, with prompt return to previous level of fertility

NORPLANT SYSTEM is reversible at any time; the contraceptive effect ceases when the capsules are removed. In one study, 40% of women wanting to conceive did so within 3 months of removal, 63% by 6 months, 76% by 12 months, and 90% by 24 months.[2]

High patient acceptance despite menstrual pattern changes

NORPLANT SYSTEM causes menstrual irregularities (the most common complaint),* which occur in many women during first-year use and diminish over time. Only 9.1% of patients discontinued during first-year use due to these changes.[3†]

Women who are thoroughly informed of potential menstrual changes and side effects are more tolerant of them when they occur.[4]

Well-received, well-liked by American women

One study of 140 users revealed that 94% were satisfied with NORPLANT SYSTEM, 91% recommended it to their friends, and 74% wanted to use it again.[5]

A 10- to 15-minute office procedure

A local anesthetic and a small 2 mm incision...little or no discomfort during insertion...proper placement should not leave a noticeable scar...in most cases sutures are not needed.

*Serious as well as minor side effects may occur (see prescribing information).

†Based on multicenter trials of 2,470 women.

Please see brief summary of prescribing information on adjacent page.

NORPLANT® SYSTEM
levonorgestrel implants

Lasts 5 years...yet is reversible

NORPLANT® SYSTEM

levonorgestrel implants

Lasts five years…yet is reversible

BRIEF SUMMARY OF PRESCRIBING INFORMATION. CONSULT THE PACKAGE LITERATURE FOR FULL PRESCRIBING INFORMATION.

Indications and Usage

The NORPLANT SYSTEM is indicated for the prevention of pregnancy and is a long-term (up to 5 years) reversible contraceptive system. The capsules should be removed by the end of the 5th year. New capsules may be inserted at that time if continuing contraceptive protection is desired.

Contraindications

1. Active thrombophlebitis or thromboembolic disorders. 2. Undiagnosed abnormal genital bleeding. 3. Known or suspected pregnancy. 4. Acute liver disease; benign or malignant liver tumors. 5. Known or suspected carcinoma of the breast.

Warnings

A. WARNINGS BASED ON EXPERIENCE WITH THE NORPLANT SYSTEM

1. *Bleeding Irregularities* — Most women can expect some variation in menstrual bleeding patterns. Irregular menstrual bleeding, intermenstrual spotting, prolonged episodes of bleeding and spotting, and amenorrhea may occur, and could mask symptoms of cervical or endometrial cancer. Overall, these irregularities diminish with continued use. Because amenorrhea may occur, missed menstrual periods cannot serve as the only identifier of early pregnancy. Perform pregnancy tests whenever pregnancy is suspected. If pregnancy occurs, the capsules must be removed. Hemoglobin concentrations found in clinical trials generally indicated that reduced menstrual blood loss is associated with NORPLANT SYSTEM use. Blood loss resulting in hemoglobin values consistent with anemia occurred rarely.

2. *Delayed Follicular Atresia* — Atresia of the follicle is sometimes delayed, resulting in enlarged follicles that are clinically indistinguishable from ovarian cysts. In the majority of women, enlarged follicles disappear spontaneously. Rarely, they twist or rupture and surgical intervention may be required.

3. *Ectopic Pregnancies* — Ectopic pregnancies have occurred among NORPLANT SYSTEM users, although clinical studies have shown no increase in the rate of ectopic pregnancies per year among NORPLANT SYSTEM users as compared with users of no method or of IUDs. The incidence among NORPLANT SYSTEM users (1.3 per 1000 woman-years) was significantly below the rate estimated for noncontraceptive users in the U.S. (2.7 to 3.0 per 1000 woman-years). Ectopic pregnancy risk may increase with duration of NORPLANT SYSTEM use and increased weight of the user. Rule out ectopic pregnancy in any patient presenting with lower-abdominal pain.

4. *Breast-feeding* — Steroids are not the contraceptives of first choice for lactating women. Levonorgestrel has been identified in breast milk. Limited data suggests no significant effects on infant growth or health when mothers used the NORPLANT SYSTEM beginning 6 weeks after parturition.

5. *Foreign-body Carcinogenesis* — Rarely, cancers occur at foreign-body intrusion sites or old scars. None has been reported in NORPLANT SYSTEM clinical trials and risk to users is judged to be minimal.

6. *Thromboembolic Disorders* — Remove capsules if active thrombophlebitis or thromboembolic disease develops. With prolonged immobilization removal should be considered.

B. WARNINGS BASED ON EXPERIENCE WITH COMBINATION (PROGESTIN PLUS ESTROGEN) ORAL CONTRACEPTIVES (OCs)

Note: Many of the side effects or risks listed below are thought to be estrogen-related; the association of the NORPLANT SYSTEM progestin-only method to these risks is unknown.

1. *Cigarette Smoking* — Cigarette smoking increases the risk of serious cardiovascular side effects from combined OC use. Risk increases with age and heavy smoking (≥15 cigarettes/day) and is quite marked in women over 35 years old.

2. *Elevated Blood Pressure* — Increase in blood pressure has been reported in combination OC users; prevalence increases with long exposure.

3. *Thromboembolic Disorders and Other Vascular Problems* — An increased risk of thromboembolic and thrombotic disease is associated with combination OC use. Estimate of relative risk is 4- to 11-fold higher for users vs. nonusers.

Cerebrovascular Disorders: Combination OCs increase the relative and attributable risk of cerebrovascular events (thrombotic and hemorrhagic strokes). Generally, risk is greatest among hypertensive women > 35 years of age who smoke.

Myocardial Infarction (MI): An increased risk of MI has been attributed to combined OC use. This is thought to be primarily thrombotic in origin and related to the estrogen component. Increased risk occurs primarily in smokers or women with other underlying risk factors for coronary-artery disease. Relative risk of heart attack for combined OC users is estimated as 2 to 6 times that for nonusers. Absolute risk is very low for women under 30 years old.

Studies indicate a significant trend toward higher MI and stroke rates with increased progestin doses in combination OCs. However, recent data indicated no increased MI risk with past use of levonorgestrel-containing OCs.

4. *Carcinoma* — Recent evidence in the literature suggests no association between OC use and increased risk of breast cancer in the overall population of users. The Cancer and Steroid Hormone (CASH) study also showed no latent effect on breast cancer risk for at least a decade following long-term use. Some of these same studies have shown an increased relative risk of breast cancer in certain subgroups; no consistent pattern has been identified. Some studies suggest an association between combination OCs and an increase in the risk of cervical intra-epithelial neoplasia in some populations of women. The extent to which such findings may be due to differences in sexual behavior and other factors remains controversial. A cause-and-effect relationship between combined OC use and breast or cervical cancer has not been established. Combination OCs may decrease ovarian and endometrial cancer risk. Irregular bleeding patterns associated with NORPLANT SYSTEM use could mask cervical or endometrial cancer symptoms.

5. *Hepatic Tumors* — Hepatic adenomas are associated with combination OC use; estimated incidence is 3 events per 100,000 users per year. Risk increases after 4 or more years of use. Hepatic adenomas are benign but may rupture and cause death through intra-abdominal hemorrhage.

6. *Ocular Lesions* — Retinal thrombosis is associated with OC use and is believed to be related to the estrogen component. However, NORPLANT SYSTEM capsules should be removed if there is unexplained partial or complete vision loss; onset of proptosis or diplopia; papilledema; or retinal vascular lesions. Undertake appropriate diagnostic and therapeutic measures immediately.

7. *Use Before or During Early Pregnancy* — Extensive epidemiological studies reveal no increased risk of birth defects when OCs are used prior to pregnancy. Studies also do not suggest a teratogenic effect when taken inadvertently during early pregnancy. No evidence suggests that risk with NORPLANT SYSTEM use is different.

8. *Gallbladder Disease* — Early studies reported an increased lifetime relative risk of gallbladder surgery in OC or estrogen users. More recent studies, however, indicate that the relative risk of gallbladder disease with OC use may be minimal; this may be related to use of OCs with less estrogen and progestin content.

Precautions

GENERAL

1. *Physical Examination and Follow-up* — A complete medical history and physical examination should be taken prior to implantation or reimplantation of NORPLANT SYSTEM capsules and at least annually during its use. Exams should include special reference to the implant site, blood pressure, breasts, abdomen and pelvic organs, including cervical cytology and relevant laboratory tests. Rule out malignancy in cases of undiagnosed, persistent or recurrent abnormal vaginal bleeding. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care.

2. *Carbohydrate Metabolism* — Altered glucose tolerance is found in some combination and progestin-only OC users. Effects of NORPLANT SYSTEM on carbohydrate metabolism appear minimal. Observe diabetic and prediabetic patients carefully while using the NORPLANT SYSTEM. Follow women being treated for hyperlipidemias closely if using the NORPLANT SYSTEM. Some progestins may elevate LDL and may render control of hyperlipidemias more difficult. (See **Warnings**.)

3. *Liver Function* — Consider removing capsules if jaundice develops. Steroid hormones may be poorly metabolized in patients with impaired liver function.

4. *Fluid Retention* — Steroid contraceptives may cause some degree of fluid retention. Prescribe with caution, and careful monitoring, in patients with conditions possibly aggravated by fluid retention.

5. *Emotional Disorders* — Consider removing capsules if significant depression occurs since the symptom may be drug-related. Observe carefully those with history of depression and consider removal if depression recurs to a serious degree.

6. *Contact Lenses* — Contact-lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist.

7. *Insertion and Removal* — Insertion is advised during the first 7 days of the cycle or immediately following abortion to insure that the woman is not pregnant and to assure contraceptive effectiveness during first cycle of use. Capsules may be inserted at any time during the cycle provided pregnancy has been excluded and a nonhormonal contraceptive method is used for the remainder of the cycle. Insertion is not recommended before 6 weeks postpartum in breast-feeding women. Follow insertion and removal instructions closely. Healthcare professionals are strongly advised to be instructed in the procedures before they attempt them. Proper insertion just under the skin facilitates removals; proper insertion and removal should result in minimal scarring. If all capsules cannot be removed at first attempt, attempt removal later when the site has healed. Bruising may occur at implant site during insertion or removal. Hyperpigmentation may occur over implant site but is usually reversible following removal. **See Full Prescribing Information for Detailed Insertion/Removal Instructions.**

8. *Infections* — Implant site infection has been uncommon (0.7%); aseptic technique and proper insertion/removal reduces possibility of infection. Institute treatment if infection occurs; remove capsules if infection persists.

9. *Expulsion* — Expulsion of capsules was uncommon; frequency increased when capsule placement was extremely shallow, was too close to incision, or when infection was present. Replace expelled capsule with new sterile capsule. Treat and cure any infection before replacement. Contraceptive efficacy may be inadequate with fewer than 6 capsules.

10. *Provisions for Removal* — Advise women that capsules may be removed at any time for any reason. Personnel instructed in removal technique should perform removal on request or at the end of 5 years of usage. Upon removal, dispose of capsules in accordance with Centers for Disease Control Guidelines for biohazardous waste.

DRUG INTERACTIONS: Reduced efficacy (pregnancy) in NORPLANT SYSTEM users has been reported when phenytoin or carbamazepine were used concomitantly. Warn NORPLANT SYSTEM users of possible decreased efficacy with use of related drugs.

DRUG/LABORATORY TEST INTERACTIONS: 1. Sex-hormone-binding globulin concentrations are decreased. 2. Thyroxine concentrations may be slightly decreased and triiodothyronine uptake increased.

CARCINOGENESIS: See **Warnings** section and Full Prescribing Information.

PREGNANCY: Pregnancy Category X. See **Warnings** section and Full Prescribing Information.

NURSING MOTHERS: See **Warnings** section and Full Prescribing Information.

INFORMATION FOR THE PATIENT: See Patient Labeling. Provide copy of patient labeling to the patient. Advise patients that Prescribing Information is available upon request. Inform prospective users of risks and benefits associated with NORPLANT SYSTEM use, with other forms of contraception, with no contraception, and about insertion/removal procedures. Informed consent from all patients may be desired in light of techniques involved with insertion and removal.

Adverse Reactions

The following have been associated with the NORPLANT SYSTEM during first year of use: many bleeding days or prolonged bleeding (27.6%); spotting (17.1%); amenorrhea (9.4%); irregular (onsets of) bleeding (7.6%); frequent bleeding onsets (7.0%); scanty bleeding (5.2%); pain or itching near implant site - usually transient - (3.7%); infection at implant site (0.7%); removal difficulties affecting subjects - based on 849 removals - (6.2%).

Controlled clinical studies suggest that the following, occurring during the first year, are probably associated with NORPLANT SYSTEM use: headache; nervousness; nausea; dizziness; adnexal enlargement; dermatitis; acne; change of appetite; mastalgia; weight gain; hirsutism, hypertrichosis, and scalp-hair loss. The following were reported with a frequency of 5% or greater during the first year and possibly may be related to NORPLANT SYSTEM use: breast discharge; cervicitis; musculoskeletal pain; abdominal discomfort; leukorrhea; vaginitis.

Overdosage

Overdosage may cause fluid retention with its associated effects and uterine bleeding irregularities.

Dosage and Administration

The NORPLANT SYSTEM consists of six Silastic® capsules, each containing 36 mg of the progestin, levonorgestrel. The total administered (implanted) dose is 216 mg. Implantation of all six capsules should be performed during the first 7 days of the onset of menses by a healthcare professional instructed in the NORPLANT SYSTEM insertion technique. Insertion is subdermal in the midportion of the upper arm about 8 to 10 cm above the elbow crease. Distribution should be in a fanlike pattern, about 15 degrees apart, for a total of 75 degrees. Proper insertion will facilitate later removal. **(See Full Prescribing Information for Detailed Insertion/Removal Instructions.)**

Cellular immunity of patients with recurrent or refractory vulvovaginal moniliasis

Ignatius W. Fong, MD,[a] Paul McCleary, MD,[b] and Stanley Read, MD[c]
Toronto, Ontario, Canada

Cellular immunity was studied in 73 patients with recurrent vaginal moniliasis and 37 healthy controls, by skin testing with the multitest CMI kit and *Candida* antigen, with measurement of lymphoblastic transformation to phytohemagglutinin, antigens of *Candida albicans,* mumps, and streptokinase. Eighteen patients (24.7%) had a hypoergic or anergic response to *Candida* antigen on skin testing versus two controls (5.4%), $p = 0.01$. Overall, the patient's lymphoblastic proliferation to mitogen and various antigens was not significantly different from that of the controls. However, a subgroup of younger women (19 to 29 years old) had impaired responses to *Candida* antigen when compared with age-matched controls, 58% versus 17%, $p < 0.005$. Most women with recurrent vaginal moniliasis had normal cellular immunity. (Am J Obstet Gynecol 1992;166:887-90.)

Key words: Cellular immunity, vaginal moniliasis

Most women will experience at least one episode of genital moniliasis in their lifetime. However, these episodes occur infrequently and are easily treated. Well-known factors associated with recurrent or refractory vulvovaginal moniliasis include diabetes mellitus, pregnancy, cellular immunodeficiency, and prolonged or recurrent antibiotic and steroid usage. There is a small group of women with recurrent genital moniliasis who are otherwise healthy with none of the above risk factors. The cause of their recurrent infections is unknown,[1] although a few studies suggest that some of these women may have a mild selective defect in cellular immunity.[2, 3] The aim of this study was to further verify the cellular immune abnormality in a larger group of patients by comparing them with a healthy control group.

Patients and methods

This study was approved by the clinical trials committee, and informed written consent was obtained from all patients and volunteers.

Patient population. Patients were selected for the study if they had four or more microbiologically proved episodes of vulvovaginal moniliasis in the past 12 months and no evidence of diabetes mellitus, chronic underlying illness, or long-term usage of steroids or antibiotics. Patients were referred to our clinic by gynecologists or community family physicians.

Volunteers. We selected healthy female volunteers who had no history of vaginal moniliasis or may have had an occasional episode ≥2 years before entry into the study. Control women selected were between the ages of 19 and 50 years, to match the ages of patients enrolled in the study.

Assessment. A detailed history and complete physical examination were done on all patients and volunteers, including a vaginal examination. Laboratory tests included complete blood cell count, white blood cell count and differential, fasting or 2-hour postprandial blood glucose, serum creatinine, calcium and phosphorus, bilirubin, alkaline phosphatase, serum alanine aminotransferase, and urinalysis. Microbiologic assessment included cultures from the vulva, vagina, mouth, and rectum for yeast.

Cellular immunity. Cell-mediated immunity was assessed by skin test response to the multitest CMI kit (Institut Merieux, Lyon, France) and to a 0.1 ml intradermal injection of fresh *Candida albicans* antigen (1:100 dilution). The response to the multitest CMI skin test was classified as normal (>5 mm), hypoergic (total score <5 mm), or anergic (0 score). A positive reaction to *C. albicans* was read as ≥5 mm of induration. Both tests were read at 48 hours after the inoculation.

Lymphoblastic transformation studies were done on separated lymphocytes (Hypaque Ficoll technique) as previously described[4] and included the mitogenic response to phytohemagglutinin and the response to specific antigens, including *C. albicans,* mumps, and streptokinase. The response to normal media was run as a control. All cultures were carried out in RPMI 1640 medium with 10% fetal calf serum. The blastogenic

NS, Not significant.

Table II. Skin test response

	Patients (n = 73)	*Controls (n = 37)*	*p Value (χ^2)*
CMI (anergic or hypoergic)	14 (19.2%)	1 (2.7%)	0.01
Candida antigen (negative reaction)	18 (24.7%)	2 (5.4%)	0.01

transformation to mitogen and antigen (after 3 and 6 days) was measured by increase in deoxyribonucleic acid synthesis incorporation of tritiated thymidine. A normal response to an antigen was empirically assessed as a greater than twofold increase over the normal medium (unstimulated) and a greater than 50-fold increase for phytohemagglutinin stimulation. A stimulation index was computed by calculating the ratio of response to antigen and mitogen over control media:

$$\text{Stimulation index} = \frac{\text{Response to antigen or mitogen}}{\text{Response to control medium}}$$

The serum inhibitory effect on blastogenic transformation was also assessed in patients and volunteers. The lymphocyte response to the antigens and mitogen was measured in the presence of autologous serum.

Statistical analysis. The characteristics of the two groups, such as mean age, and analysis of continuous variables, such as stimulation index, were compared by use of the Student unpaired *t* test. In comparison of rates of abnormal skin tests (anergic or hypoergic reaction), abnormally low response to the various antigens, use of oral contraceptives, a χ^2 test, or Fisher exact test (one tailed) was used.

Results

Seventy-three patients and 37 volunteers were enrolled in the study. The demographic features are summarized in Table I. There were no significant differences in the use of oral contraceptives or underlying illnesses. The mean age of the patients was statistically higher (32.3 vs 28.9 years) but not considered of physiologic importance.

Results of the skin testing (delayed hypersensitivity) are shown in Table II. Although there was a significant difference in response between the two groups, only 19% and 24% of the patients showed anergy or hypoergic response to CMI or *Candida* antigen, respectively. Fourteen of the patients and one volunteer who had an anergic reaction to CMI and *Candida* antigen (1 : 100 dilution) were restested with a stronger strength of *Candida* antigen (1 : 10 dilution). Of these, only one patient had a negative reaction (<5 mm of induration).

Lymphoblastic transformation. One hundred thirty-eight tests were done in 73 patients, and 71 tests were performed in 37 controls. Thirty-nine patients had repeat testing, 15 patients on four separate occasions, nine patients on three occasions, and 15 patients on two occasions. Thirteen controls had repeat testing, 11 on four occasions and two with two tests.

Table III summarizes the results of the lymphoblastic transformation response to the various antigens and mitogen.

Overall, the patients' lymphoblastic responses to the various antigens and mitogen were not significantly different from those of the controls. The exception was the response to mumps antigen, which was significantly greater in the patients versus controls ($p = 0.01$). However, in a subgroup of patients 19 to 29 years old (Table IV), a greater number had low responses to *C. albicans* antigen when compared with the control group in the same age bracket, 58% versus 17% ($p < 0.005$). The

Table III. Lymphoblastic transformation response

Antigen	*Patients (n = 73)*	*Controls (n = 37)*	*p Value*
C. albicans			
Low response*	39 (53%)	13 (35%)	0.20
Stimulation index, mean ± SD†	7.6 ± 23.3	8.8 ± 19.0	0.35
Mumps			
Low response*	15 (21%)	13 (35%)	>0.1
Stimulation index, mean ± SD†	13.9 ± 21.8	8.3 ± 9.7	<0.01
Streptokinase			
Low response*	15 (21%)	10 (27%)	>0.2
Stimulation index, mean ± SD†	13.3 ± 19.4	10.2 ± 12.9	<0.1
Phytohemagglutinin			
Low response*	16 (22%)	11 (30%)	>0.1
Stimulation index, mean ± SD†	126.4 ± 113.3	107.6 ± 110.5	0.15

*Calculated on the presence of at least one abnormal test result in a given patient.
†Calculated from the total tests performed.

reverse effect was seen in the older age groups where a low response to *C. albicans* antigen was greater but not statistically significant in the control group.

The decrease in lymphoblastic transformation to *Candida* antigen in both patients and controls was often not persistently detected. Fifteen patients and 11 controls with initially low lymphocyte proliferation to *Candida* had repeat testing on four separate occasions. All four test results were abnormal in only one control and no patients; three of the test results were abnormal in five patients and four controls, and only two or fewer of the test results were abnormal in six patients (40%) and six controls (54.5%).

There was no significant inhibitory effect of serum on the patients' or volunteers' lymphoblastic responses. The lymphoblastic response and stimulation index with the various antigens and mitogen were unchanged with the addition of serum.

40-50 yr			
Low response	5 (56%) (n = 9)	4 (67%) (n = 6)	NS

NS, Not significant.

Comment

Recurrent or refractory vaginal moniliasis is an uncommon illness in otherwise healthy women but is associated with protracted discomfort, stress, and frustration in patients. Most family physicians and gynecologists see patients with this condition, but the exact incidence is unknown.

Few studies have addressed the issue of the underlying etiology of this condition. Certainly, conditions with impaired cellular immunity are well-known causes of recurrent moniliasis, such as the acquired immunodeficiency syndrome, immunosuppressive therapy, leukemia, lymphoma, endocrinopathies, chronic mucocutaneous candidiasis, and pregnancy. However, in most of these conditions (except for pregnancy), the moniliasis is not restricted to the involvement of vulvovaginal mucosa. None of the patients studied in our clinic or reported on by others have had extragenital moniliasis.

Studies of the humoral immunity in women with recurrent vaginal moniliasis have not shown any defects.[5] In vaginal candidiasis the antibody response is mainly local, consisting of secretory immunoglobulin A. The pathogenesis of recurrent vulvovaginal moniliasis remains obscure, because the majority of patients have no recognized predisposing factors.[6]

Few studies have investigated the cellular immunity in women with recurrent vaginal moniliasis. Syverson et al.[2] examined the cellular immunity in 9 patients and 29 controls. With skin testing only 33% of patients and 55% of controls showed hypoergy or anergic reaction to *C. albicans.* Thus an impaired cutaneous response to *C. albicans* antigen was not greater in the patients than in the controls. Our findings show a similar percentage of patients (24.7%) with negative reaction to *C. albicans* but a much lower negative reaction in the controls (5.4%).

Syverson et al.[2] also studied lymphocyte transformation and leukocyte migration inhibition. No difference in results was found between patients and controls, but the authors concluded that their study suggests a lack of cellular immune response to *Candida* antigen in women with chronic *Candida* vaginitis. Our study failed

to show any significant defects in lymphoblastic response to *Candida* antigen in the entire patient population, compared with controls. There was also no difference in response to mumps, streptokinase, and phytohemagglutinin between the two groups. However, patients 19 to 29 years old had significantly lower lymphoblastic response to *C. albicans* antigen than age-matched controls. The explanation for this observation is unclear, but it may explain differences between studies and it emphasizes the importance of age-matched controls in future studies.

Witkin et al.[3] reported on the cellular immunity of six patients with recurrent vaginal moniliasis and six controls. No differences were observed in the proliferative responses of lymphocytes to mitogens, but the proliferative response to *C. albicans* was decreased in all patients.

Moreover, serum from patients also suppressed the proliferative response of controls' lymphocytes to *C. albicans*, thus suggesting that a soluble component in sera that blocks the response of peripheral blood lymphocytes to *C. albicans* is produced in these patients. These results are clearly at variance with ours and can only be partly explained. Our study involves a much larger patient population, and it is possible that the patients studied by Witkin et al.[3] fall into the younger age group of 19 to 29 years, where a decrease in proliferative responses of lymphocytes to *C. albicans* occurred in nearly 60% of our patients. However, the ages of the patients studied by Witkin et al.[3] were not provided. Also, the methods used in our study are somewhat different, and so the results may not be directly comparable.

More recently the same group[7] reported on the cellular immunity of a larger population of patients ($N = 65$). Again they found that *Candida*-directed proliferation to *Candida* antigen was reduced at least 70% below the mean control value in 73% of patients. Further analyses on selected patients demonstrated that lymphocytes of patients responded in the normal range to *Candida* if incubated in the presence of control macrophages. It should be noted that even in our patients with low blastogenic response to *Candida* antigen the defect was not often permanent and normal results were obtained on some repeat testing.

Mathur et al.[8] previously reported that lymphocyte responses to concanavalin A were significantly lower than those of matched controls in 26 patients with chronic vaginal moniliasis, whereas lymphocyte response to phytohemagglutinin were normal. Because we did not use concanavalin A in our study and Mathur's group did not test *Candida* and mumps antigen, we are unable to compare the results. The study by Mathur et al.,[8] however, does suggest that there may be a defect in the cytotoxic/suppressor T cells of these patients.

In summary, the cellular immunity of most women with recurrent vaginal moniliasis is normal. A subgroup of women, between 19 and 29 years old, showed a higher incidence of impaired lymphocyte proliferative response to *C. albicans* (58%), and only 25% of all patients demonstrated impaired cutaneous delayed hypersensitivity to *Candida* antigen. Thus in the majority of patients the pathogenesis of the recurrent vaginal moniliasis remains unknown.

We thank M. Simbul for his technical assistance.

Validity of postnatal assessments of gestational age: A comparison of the method of Ballard et al. and early ultrasonography

Greg R. Alexander, MPH, ScD,[a] Francois de Caunes, MD, MPH,[b] Thomas C. Hulsey, MSPH, ScD,[c] Mark E. Tompkins, PhD,[d] and Marilee Allen, MD[e]

Minneapolis, Minnesota, Guadeloupe, French West Indies, Charleston and Columbia, South Carolina, and Baltimore, Maryland

This study investigates the accuracy of the postnatal gestational age assessment method of Ballard et al. to predict very preterm, preterm, term, postterm, and small-for-gestational-age infants, with gestational age by early ultrasonography used as the gold standard. Sensitivity, specificity, and predictive value were examined for each gestational age category, with 4193 single live births occurring during the period from 1982 through 1989 with an ultrasonographic examination done by 20 weeks' gestation and a postnatal assessment at 28 to 44 weeks. These data indicate that the postnatal assessment overestimated the gestational age of preterm births, resulting in an underestimation of very preterm and preterm percentages. Nearly three fourths of the postterm births by ultrasonography were misclassified by the method of Ballard et al. because of underestimation of postterm gestational ages. These data indicate that, for research purposes, appreciable misclassification of preterm, postterm, and small-for-gestational-age infants will occur if gestational age is determined by the technique of Ballard et al. (Am J Obstet Gynecol 1992;166:891-5.)

Key words: Gestational age, prematurity, postterm delivery, intrauterine growth, ultrasonography

Ascertainment of gestational age is essential for the evaluation of newborn risk status. Classically, this determination has been based on the date of last normal menses, if that date was considered reliable. However, the accuracy of this measure has been questioned, and ultrasonography has been proposed as a more precise method for estimating gestation age.[1]

When neither a reliable date of last normal menses (LMP) nor an early ultrasonographic examination is available, clinical postnatal assessments of newborn maturity have been used to estimate the length of pregnancy duration.[2, 3] On the basis of observations of the physical and neurologic characteristics of the newborn, these assessments have been shown to be highly correlated with the LMP interval, have been touted as a valid alternate measure of gestational age,[2-6] and have been frequently used in gestational age–related research.[7]

Lower maternal socioeconomic status has been associated with a missing or uncertain LMP and with late entry into prenatal care, which may preclude an early ultrasonographic examination.[8-12] These same characteristics have further been associated with low birth weight and preterm delivery.[11-15] In these situations, postnatal assessments are of increasing importance in the determination of gestational age. In recent years, however, concern has grown over the inability of postnatal assessments to provide valid estimates of gestational age in low-birth-weight and preterm infants.[16-21] In this study we investigated the ability of a postnatal assessment method to accurately assess the gestational age of very preterm, preterm, term, postterm, and small-for-gestational-age (SGA) infants with gestational age by early ultrasonography used as the gold standard.

Methods

Data were obtained from the Medical University of South Carolina computerized Perinatal Information System.[22] The racially mixed service population of this regional perinatal center is largely composed of lower-income patients. Patient records were prospectively re-

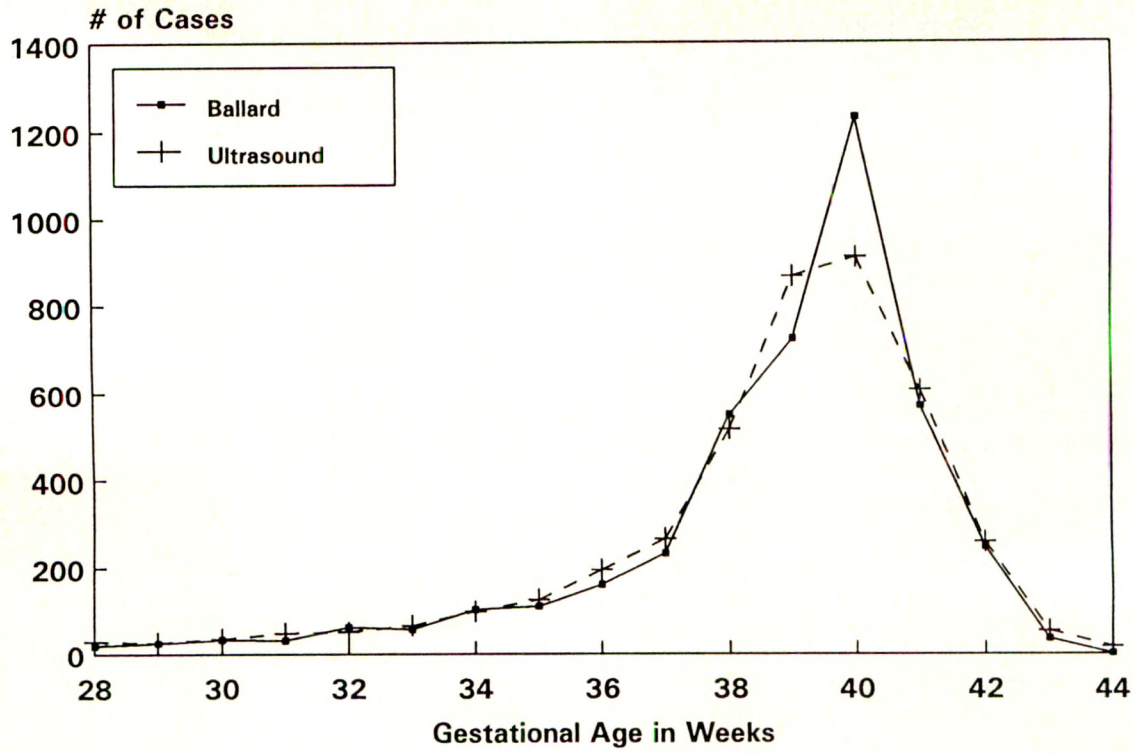

Fig. 1. Gestational age distribution by method of Ballard et al. and ultrasonography.

Table I. Gestational age interval and distribution measures by method by Ballard et al. and early ultrasonography

	Ballard et al.	*Ultrasonography*
Very preterm (<33 wk) (%)	4.05	4.94
Preterm (<37 wk) (%)	14.33	16.53
Term (37-41 wk) (%)	78.89	75.51
Postterm (≥42 wk) (%)	6.77	7.97
SGA (%)	11.34	9.43
Mean ± SD (wk)	38.77 ± 2.58	38.60 ± 2.86
Skewness	−1.61	−1.59
Kurtosis	3.07	3.34

viewed by data clerks with training in medical record abstraction, and a standardized data collection method was used throughout the study period.

Single live births with delivery in the Medical University of South Carolina Hospital during the period from 1982 through 1989 with an ultrasonographic examination by 20 weeks' gestation and a postnatal assessment at 28 to 44 weeks, according to the method proposed by Ballard et al.,[3] were selected for analysis. The Ballard postnatal assessment was routinely performed for all deliveries and was administered by trained clinicians in the course of normal clinical practice. There were 4193 cases that met the study criteria. Infants with conditions that precluded the administration of the Ballard method (e.g., major congenital anomalies) were excluded.

Gestational age by ultrasonography was largely established by a combination of biparietal diameter, femur length, and abdominal circumference.[23] SGA was determined on the basis of the standard provided by Brenner et al.,[24] representing those cases <10th percentile of the birth weight distribution for gestational age.

Results

Although the gestational age distribution by Ballard and ultrasonography exhibit similar mean values (Table I), the Ballard distribution, displayed in Fig. 1, reveals a greater concentration of cases around the 40-week value, with fewer cases in the extreme tails of the distribution. Table I provides, by Ballard and ultrasonography, the percentages of very preterm (<33 weeks), preterm (<37 weeks), term (37-41 weeks), postterm (≥42 weeks), and SGA. The ultrasonography very preterm, preterm and postterm percentages exceed the Ballard percentages, whereas the ultrasonography SGA percentage is lower than that indicated by Ballard. The correlation between the two measures is $r = 0.79$.

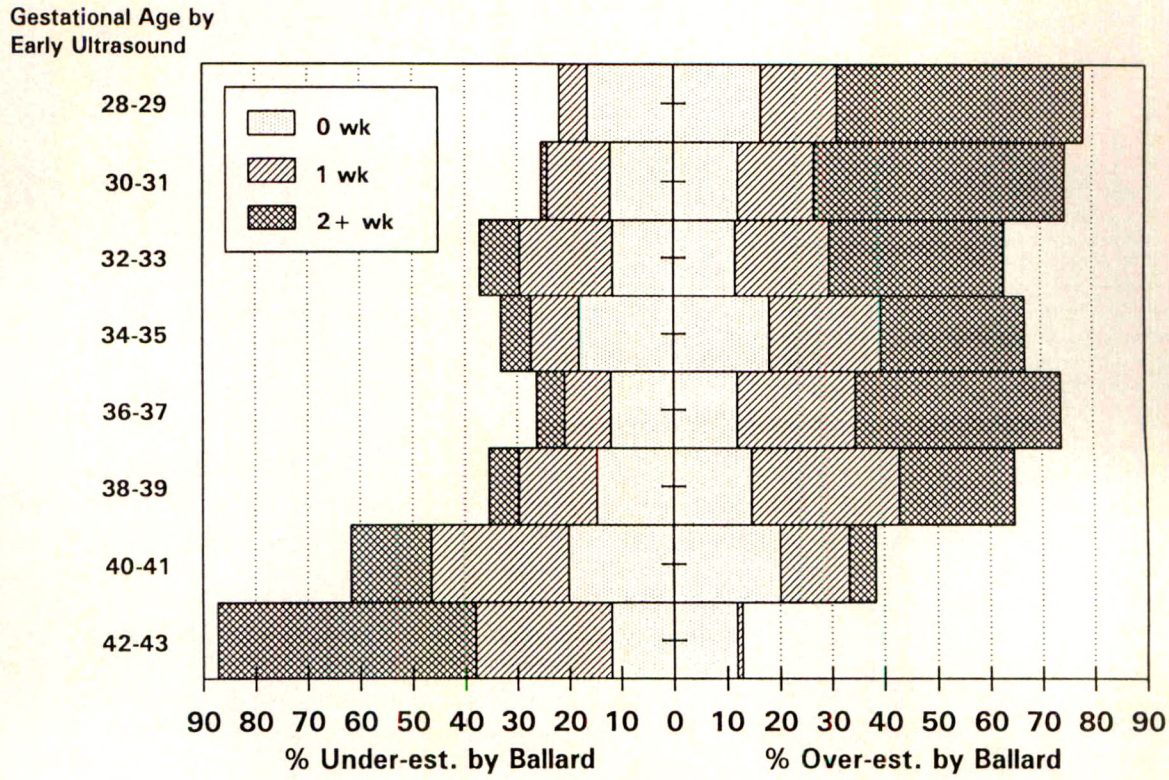

Fig. 2. Percent of cases with early ultrasonography gestational age overestimated and underestimated by Ballard by ≥1 week.

Table II. Efficacy of method by Ballard et al. to identify gestational age–based risk categories as determined by early ultrasonography

	Gestational age–based risk categories				
	Very preterm	*Preterm*	*Term*	*Postterm*	*SGA*
Sensitivity	66.18	72.15	90.93	26.95	76.46
Specificity	99.17	97.11	58.23	94.97	95.44
Positive predictive value	80.59	83.19	87.03	31.69	63.58
Negative predictive value	98.26	94.63	67.57	93.76	97.50

Sensitivity is the percent of cases placed in the category by ultrasonography that were also so identified by Ballard. Specificity is the percent of cases excluded from the category by ultrasonography that were also excluded by Ballard. Positive predictive value is the percent of cases placed in the category by Ballard that were also so identified by ultrasonography. Negative predictive value is the percent of cases excluded from the category by Ballard that were also excluded by ultrasonography.

The percentage of cases with a gestational age by ultrasonography either overestimated or underestimated by Ballard by ≥1 week is shown in Fig. 2. Before 40 weeks there is a decided tendency by Ballard to overestimate the ultrasonographic value. At the interval from 28 to 29 weeks, nearly 50% of the cases were overestimated by Ballard by ≥2 weeks. Among postterm births approximately 50% of the cases were underestimated by Ballard by ≥2 weeks.

Table II reports measures of the efficacy of Ballard to identify the various ultrasonographically determined gestational age groups. Two thirds of the very preterm infants identified by ultrasonography were classified as very preterm by Ballard (sensitivity 66%). For postterm births the sensitivity by Ballard was only 27%. Of those infants designated postterm by Ballard, fewer than one third were postterm by ultrasonography (positive predictive value 32%). Fewer than two thirds of the infants determined SGA by Ballard were SGA by ultrasonography (positive predictive value 64%).

Table III displays the efficacy of Ballard to identify SGA infants as determined by ultrasonography for low birth weight (<2500 gm) and normal birth weight (≥2500 gm) infants. For low-birth-weight infants, approximately two thirds of the infants identified as SGA by Ballard were SGA by ultrasonography. For normal-

Table III. Efficacy of method by Ballard et al. to identify low- and normal-birth-weight infants as SGA with early ultrasonography used as gold standard

	Low birth weight (<2500 gm)	*Normal birth weight (≥2500 gm)*
SGA by Ballard (%)	46.06	5.00
SGA by ultrasonography (%)	38.18	4.18
Sensitivity	80.57	69.59
Specificity	75.25	97.82
Positive predictive value	66.78	58.19
Negative predictive value	86.25	98.66

Sensitivity is the percent of cases placed in the category by ultrasonography that were also so identified by Ballard. Specificity is the percent of cases excluded from the category by ultrasonography that were also excluded by Ballard. Positive predictive value is the percent of cases placed in the category by Ballard that were also so identified by ultrasonography. Negative predictive value is the percent of cases excluded from the category by Ballard that were also excluded by ultrasonography.

birth-weight infants, the positive predictive value of Ballard was even lower (58%).

Ultlrasonographic technology was changing over this period and showed an increased use during the latter years of the study period. An examination of the data by year did not reveal a temporal trend in these findings.

Comment

The greater central concentration of the Ballard distribution suggests a tendency by Ballard examiners to err toward the mean. For preterm births the postnatal assessment overestimated the early ultrasonography-based gestational age, resulting in an underestimation of very preterm and preterm percentages. In addition, nearly three fourths of the postterm births by ultrasonography were misclassified by Ballard because of underestimation of postterm gestational ages. Because of these systematic errors, the conventional assumption that postnatal assessments have a random ±2-week error margin appears faulty for nonterm births. Agreeing with previous findings,[16-21] these results raise serious questions regarding the ability of the Ballard technique to accurately identify either preterm or postterm infants.

It has been previously reported that the Ballard method underestimates the gestational age of SGA births compared with non-SGA births.[6] This was also found in this study (data not shown). The overestimation by Ballard of the gestational age of non-SGA births results for some cases in the application of higher-birth-weight criteria to establish SGA. This leads to a misassignment of some of these births to the Ballard SGA category and inflates the overall Ballard percentage of SGA births.

These data indicate that, for research purposes, appreciable misclassification of preterm, postterm, and SGA infants will occur if gestational age is determined by Ballard. It further suggests that given a case series for which some of the cases are lacking gestational age information from a certain LMP or an early ultrasonographic examination, it is unwise to substitute a gestational age value derived from a postnatal assessment. As an uncertain LMP or missing early ultrasonography is more likely to occur among cases with lower socioeconomic characteristics, as determined by maternal age, race, education, marital status, or payment method, this practice may produce biased gestational age estimates for higher-risk subgroups, thereby confounding the research results.

The initial postnatal assessment validation studies were conducted with a limited number of examiners with an emphasis on reliability and internal validity issues.[2, 3] The Ballard scores in this investigation were taken under the more normal practice conditions found in a large university hospital by numerous trained recorders who were unaware of this research agenda. As such, the quality of these postnatal assessment data may more closely reflect that typically found on large perinatal data bases and what is more commonly available for research purposes as a measure of gestational age. Although more controlled and limited investigations may improve on these results, these data have implications for the accuracy of postnatal assessment methods used in more broad and representative situations and for the many studies that use postnatal assessment estimates obtained in a similar manner.

Although high correlations between postnatal assessments and gestational age from LMP have been demonstrated, the adequacy of correlation techniques to establish the validity of postnatal assessments has been questioned.[19, 25] In these data we find that the postnatal assessment was most sensitive in identifying births that were determined to be at term by ultrasonography. Unfortunately, a postnatal assessment is most useful if it can also provide an accurate assessment of nonterm infants. As evidence mounts concerning the inability of these methods to accurately identify infants

in more at-risk gestational categories, future research should focus on modifying or reformulating current postnatal assessment criteria.

Dr. Donna J. Petersen is acknowledged for her thoughtful comments and support during the preparation and revision of this manuscript.

Diagnosis of cervical change in pregnancy by means of transvaginal ultrasonography

Gary M. Joffe, MD, Gerardo O. Del Valle, MD, Luis A. Izquierdo, MD, George J. Gilson, MD, James F. Smith, MD, Molly S. Chatterjee, MD, and Luis B. Curet, MD

Albuquerque, New Mexico

There are no absolute objective diagnostic criteria for cervical incompetence. Abdominal and endovaginal ultrasonographic assessment of endocervical length, both of which have been associated with technical problems, have been used to establish the diagnosis. Cervical cerclage may be useful in preventing silent cervical dilatation; however, no prospective trials with and without cerclage have been performed when endocervical shortening has been demonstrated by ultrasonography. (AM J OBSTET GYNECOL 1992;166:896-900.)

Key words: Cervical incompetence, endovaginal ultrasonography, cervical cerclage

Diagnosing cervical incompetence is difficult because there are no specific tests or criteria that confirm or exclude the diagnosis.[1] At our institution, in April, 1990, Kushnir et al.[2] reported on the use of transvaginal ultrasonography to determine the normal length of the endocervical canal during gestation. We use this technique in the routine monitoring of patients at risk for cervical incompetence. The following summaries describe two cases in which transvaginal ultrasonographic assessment of the cervix resulted in the decision to place a cerclage.

Case reports

Case 1. The patient, a gravida 4, para 0, black woman, had a history of two first-trimester spontaneous abortions and a pregnancy loss at 22 weeks. She reported no perception of labor before spontaneous rupture of membranes and subsequent rapid delivery of a stillborn infant. Other pertinent history included chronic hypertension, smoking one pack of cigarettes

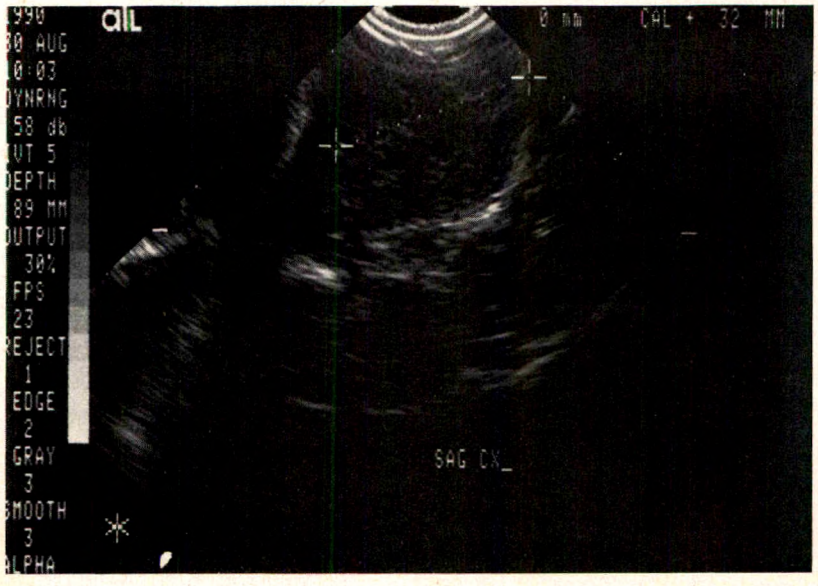

Fig. 1. Endovaginal ultrasonographic measurement indicates that endocervical length of patient in case 1 has decreased to 32 mm at 25 weeks' gestation.

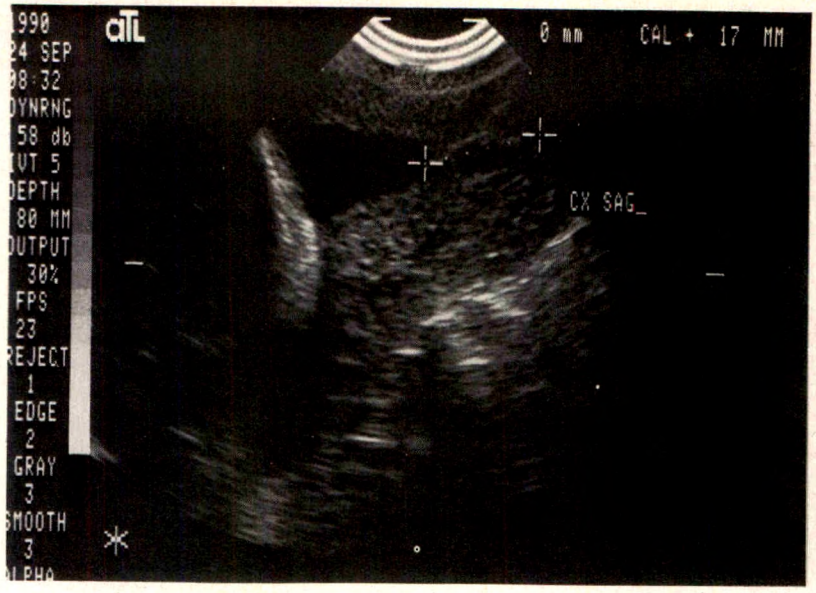

Fig. 2. At 28 weeks of gestation there is marked beaking of chorioamnion with internal os dilatation. Length of remaining endocervix is 17 mm.

per day, and consuming three to five bottles of beer per week. She presented to the Maternal-Fetal Medicine clinic at our institution at 18 weeks' estimated gestational age. A physical examination revealed bacterial vaginosis, which was subsequently treated with metronidazole (Flagyl, Searle & Co., Chicago). In results of the digital examination, the cervix was described as "long, thick, and closed." Vaginal ultrasonographic assessment revealed an endocervical length of 55 mm. Estimated gestational age indicated by transabdominal ultrasonography at this time was 18 weeks 6 days.

To determine the patient's endocervical length, serial ultrasonographic examinations were performed with an ADR Ultramark IV scanner (ADR, Bothel, Wash.) with either a 3.5 or 5.0 MHz transvaginal transducer. The endocervical length decreased from 63 to 32 mm between 22 weeks and 25 weeks of gestation. At 28 weeks marked dilatation of the internal os with "beaking" of chorioamnion was visible. The remaining endocervix measured 17 mm in length (Figs. 1, 2, and 3).

The patient was evaluated for preterm labor by means of external tocodynamometry, but no contractions were noted. The extent of cervical shortening was not evident on digital examination. A cerclage was placed at 29 weeks' gestation. At surgery, the cervix appeared closed and the membranes were not visible, in spite of marked dilatation of the internal os seen on transvaginal ultrasonography. The pregnancy was further complicated by mild preeclampsia and chronic hypertension.

On Nov. 8, 1990, at 35 weeks' estimated gestational age, the patient experienced spontaneous rupture of membranes and the cerclage was removed. She was delivered of a female infant who weighed 1930 gm with Apgar scores of 9 at both 1 and 5 minutes. The infant went home with her mother on postpartum day 2.

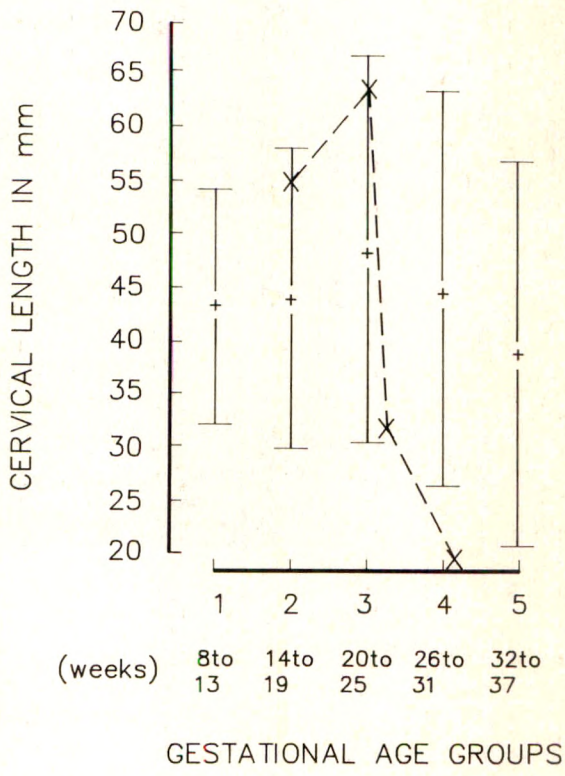

Fig. 3. *Plus sign,* Median (±2 SD) for endocervical length at various stages of gestation as reported by Kushnir et al.[2] ×, Measurement of endocervical length of patient in case 1 at 18, 21, 25, and 28 weeks of gestation.

Case 2. The patient, a 24-year-old, gravida 3, para 0 white woman, first presented to the Maternal-Fetal Medicine clinic at 10 weeks of gestation. She reported a history of two first-trimester spontaneous abortions

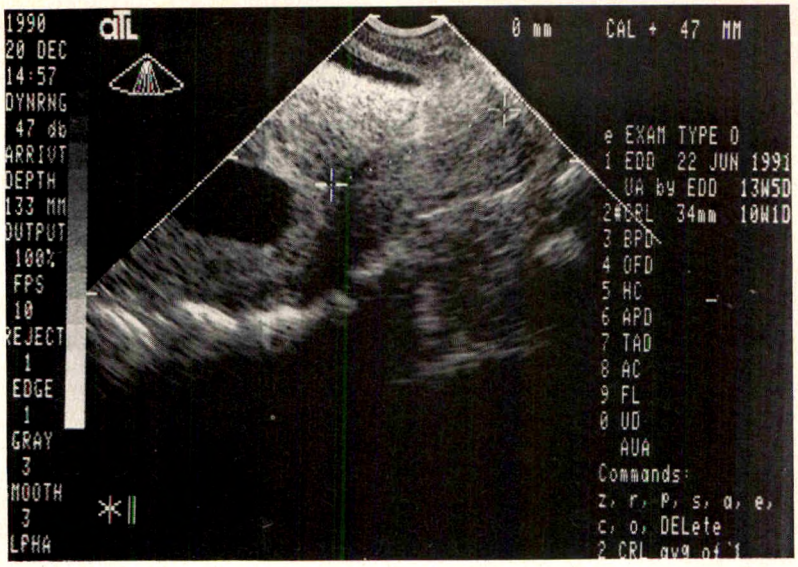

Fig. 4. Endocervical length of patient in case 2 at 10 weeks of gestation. Note prominent endometrial stripe.

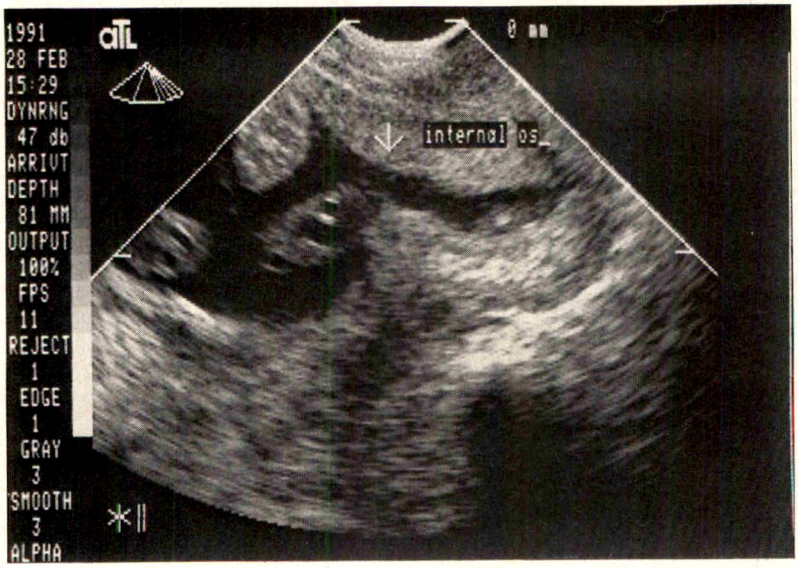

Fig. 5. Same patient as in Fig. 4 at 19.5 weeks' gestation. Note beaking of amniotic fluid past internal os of cervix. Also note section of umbilical cord presenting at internal os. Endocervical length was measured as 27 mm.

followed by curettage and a pregnancy loss at 24 weeks' gestation. Her history was otherwise unremarkable, and she had had no known in utero exposure to diethylstilbestrol.

Endovaginal ultrasonographic assessment of the cervix was completed in a serial fashion. At 10 weeks' estimated gestational age, the endocervical length measured 47 mm (Fig. 4). At 15 weeks the endocervical length was reportedly 37 mm. At 19.5 weeks the endocervical length had diminished to 27 mm, and there was marked beaking of the chorioamnion into the endocervical canal (Fig. 5). The decision was made to place a cerclage. Speculum examination of the cervix at the time of surgery revealed that the bag of waters was visible at the cervical os. The bladder was filled with 300 ml of sterile water to assist in retracting the bag of waters from the cervix. Cerclage placement was otherwise uneventful.

The patient returned for an ultrasonographic examination to determine interval growth at 25 weeks'

gestation. The amniotic fluid index was 7.2 cm. Oligohydramnios as a result of rupture of membranes at cerclage placement was strongly suspected, although the patient denied fluid leakage. Amniocentesis with dye instillation was performed, and rupture of membranes was not documented. Five days later the repeat amniotic fluid index was 14.2 cm.

The patient presented again at 33 weeks' gestation with complaints of uterine contractions and vaginal bleeding. Intravenous tocolysis was initiated, and amniocentesis was performed to rule out intraamniotic infection and to document lung maturity. Amniotic fluid Gram's stain and cultures were negative. The lecithin/sphingomyelin ratio was 6.7 with phosphatidylglycerol present. The estimated fetal weight was 1800 gm. The decision was made to remove the cerclage because the patient continued to labor in spite of tocolysis. The patient was quickly delivered of an 1810 gm female infant with Apgar scores of 7 and 9 at 1 and 5 minutes, respectively. Inspection of the placenta revealed an adherent 3 cm clot consistent with chronic abruptio placentae.

Comment

The diagnosis of cervical incompetence relies on the demonstration of cervical dilatation in the absence of uterine contractions. However, as demonstrated in case 1, significant and dangerous shortening of the endocervix may occur before dilatation of the cervix can be demonstrated by speculum examination or digital palpation. Thus diagnostic methods such as transvaginal ultrasonography, which more objectively demonstrate earlier cervical changes, become very attractive.

In addition, a significant percentage of primigravid and multiparous women have dilatation of 1 to 2 cm at 21 to 28 weeks' gestation, and they do not have a higher rate of preterm delivery. With the development of nomograms of endocervical length in large population studies, identification of this group of patients with "physiologic" cervical dilatation who are at low risk for preterm delivery may some day be accomplished.

Ayers et al.[3] established a nomogram for cervical length in a group of 142 women who were subsequently delivered at term. According to Ayers et al., "Cervical length observed . . . was remarkably constant, averaging 52 mm until effacement began at 33-34 weeks gestation." Both Kushnir et al.[2] and Ayers et al.[3] have demonstrated no significant difference in cervical length between primigravid and multigravid women who were eventually delivered at term. However, in a study by Kushnir et al.,[2] in contrast to that by Ayers et al.,[3] a shorter mean cervical length at all gestational ages and a significant increase in cervical length between 20 and 25 weeks' gestation were noted.

The differences noted (a shorter cervical length and variability in length with increasing gestational age) might result from the greater diagnostic accuracy of the vaginal probe. As Kushnir et al.[2] stated, "Cervical distortion is avoided because the vaginal probe is in close proximity to the cervix."

The demonstration of beaking of membranes with internal os dilatation probably represents the final stage of endocervical shortening before frank prolapse past the external os. In our experience serial scans have always demonstrated persistent endocervical shortening before beaking of the membranes.

When either transvaginal or abdominal ultrasonography is used to evaluate endocervical length, several measurements should be repeated during the session. Transient contraction of the lower uterine segment can lead to false elongation of endocervical length and can give the false image of beaking of the membranes. As a result of the obstetric histories of the patients described in this review, many clinicians would have opted for immediate placement of cerclage. Placement of cerclage has become the standard of care for these patients, in whom other causes of recurrent midtrimester pregnancy loss, such as uterine anomaly or infection, have been eliminated. However, significant data on which to make the decision to place cerclage are lacking. Most reports of successful pregnancy outcome after placement of cerclage use the patients' earlier pregnancy outcomes for comparison. These comparisons are not valid, because several series report that as many as 70% of patients who have a mid-trimester loss will be delivered at term with no treatment in their subsequent pregnancies. Because placement of cerclage has potential risks even in the second trimester, reserving the procedure for those patients who have endocervical shortening demonstrated on transvaginal scan might be prudent. The evaluation of endocervical length may also be valuable in the patient with a history suggestive of cervical incompetence, but who presents for her first prenatal care after 20 weeks' gestation.

The question of whether to place a cerclage in the late second or early third trimester after the demonstration of significant shortening in cervical length remains difficult. In the study of Ayers et al.[3] 97% of patients who received a cerclage after demonstration of cervical shortening were delivered after 35 weeks' gestation. However, to our knowledge there are no prospective studies comparing the rate of preterm delivery after demonstrated endocervical shortening with and without cerclage. In case 1 we thought that the risk of preterm delivery outweighed the hazards involved in the placement of cerclage. However, that patient may have had the same outcome with bed rest alone.

In case 2 the patient had at least two of the problems

encountered when a cerclage is placed in the late second trimester and after dilatation of the internal os: possible preterm rupture of the membranes and preterm labor.

In summary, vaginal ultrasonography may provide a more objective basis for the diagnosis and management of cervical incompetence. A prospective study is needed to evaluate the risks and benefits of cerclage in the prevention of preterm delivery when cervical shortening has been demonstrated by vaginal ultrasonographic assessment.

Contraceptive compliance with a levonorgestrel triphasic and a norethindrone monophasic oral contraceptive in adolescent patients

Elizabeth R. Woods, MD, MPH,[a] Estherann Grace, MD,[a] Kathryn Klein Havens, MD,[a] James L. Merola, PhD,[b] and S. Jean Emans, MD[a]

Boston, Massachusetts

OBJECTIVE: This study was undertaken to assess the impact of two low-dose oral contraceptive pills on compliance and side effects in adolescent patients.

STUDY DESIGN: The use of a levonorgestrel-containing triphasic pill ($N = 114$) was compared with that of a monophasic (1 + 35) norethindrone-containing pill ($N = 110$) at two different sociodemographic sites.

RESULTS: No significant difference in compliance or pill satisfaction was observed between the pills. Socioeconomic factors were the overriding predictors of compliance. At 3 and 12 months of follow-up, there were significantly fewer compliants of overall side effects ($p < 0.001$ and $p = 0.004$, respectively), breakthrough bleeding ($p = 0.017$ and $p = 0.018$), and pill amenorrhea ($p = 0.002$ and $p < 0.001$) among users of the triphasic pill. Mean weight change at 12 months was +1.1 kg for the monophasic pill and −0.1 kg for the triphasic pill. All known pregnancies occurred among noncompliant city clinic patients.

CONCLUSIONS: Adolescents experienced fewer side effects with the triphasic pill than with the monophasic one, but compliance was the same. (Am J Obstet Gynecol 1992;166:901-7.)

Key words: Contraceptive compliance, adolescents, birth control, oral contraceptive

Adolescent pregnancy continues to be a major problem in the United States, with rates considerably higher than those of other developed countries.[1, 2] Initiation of contraception continues to be delayed and inconsistent.[1-11] In a previous study in our clinics,[3] many of the predictors of compliance in adolescents with follow-up at three different sites (an inner-city adolescent clinic, a birth control clinic in a midsized industrial city, and a suburban private practice) were sociodemographic factors that are difficult for health care professionals to change. However, the lack of real or perceived side effects was associated with improved compliance.

The new triphasic oral contraceptive pills have lower progestin and estrogen content than many commonly prescribed monophasic pills. However, it is unclear if adolescents can follow the more complex packaging of the triphasic pills. This study was undertaken to assess the impact on reported side effects and adolescent compliance with a levonorgestrel-containing triphasic pill compared with our previous study of a norethindrone-containing (1 + 35) monophasic pill.[3]

Material and methods

Two hundred twenty-four patients who were starting oral contraceptives for birth control for the first time were entered into the study. Patients were recruited from two different sites: a hospital-based city clinic ($N = 124$) and a suburban adolescent private practice ($N = 100$) with 114 receiving a levonorgestrel-containing triphasic pill (Triphasil 28d, Wyeth-Ayerst Laboratories, Philadelphia) and 110 receiving a monophasic norethindrone-containing pill (Norinyl 1 + 35, Syntex Laboratories, Palo Alto, Calif.). In compliance with our Human Investigation Committee's guidelines for quality improvement, standard medical care was given and informed consent for initiating oral contraceptive pills was obtained.

As in our previous study, which included only patients using a monophasic pill,[3] data about demographics, sexual history, previous birth control use, career goals, concerns about potential side effects, and parental and partner knowledge of the contraceptive pill were collected. A physical examination including height, weight, blood pressure, and pelvic examination was performed. Each patient was provided with a 3-month supply of contraceptive pills. Patients were given

the monophasic pill in the first block of time (December 1983 through June 1984) and the triphasic pill in the subsequent block of time (May 1985 through June 1987).

Follow-up information was obtained at the 3-month visit and at the visit closest to 12 months for long-term follow-up. Data at follow-up visits included blood pressure, weight, menstrual pattern, side effects, pregnancy, and compliance with taking the oral contraceptives. Compliance was defined as both returning for the follow-up visit and taking the pill as prescribed or stopping the pill because of no longer needing contraception.

Data analysis was performed with the SAS statistical package.[12] Fisher's exact test (two-tailed) or χ^2 test was used for all categoric variables. For continuous variables the appropriate *t* test was performed when comparison groups had equal variances (as assessed by the *F*-test result), and an approximation of the *t* test was performed when comparison groups had unequal variances.[13] All results are reported as mean ± SD. SAS's general linear model, stepwise regression, and CATMOD logistic regression subroutines were used to assess the predictor's relative contribution to R^2 and the overall significance of the models.

Results

The mean age of the 224 patients was 17.2 ± 2.1 years; 21% received Medicaid; 37% were black and 63% white; 46% resided in the city, 37% in the suburbs, and 17% at school. There were no significant demographic differences between patients started on a regimen of

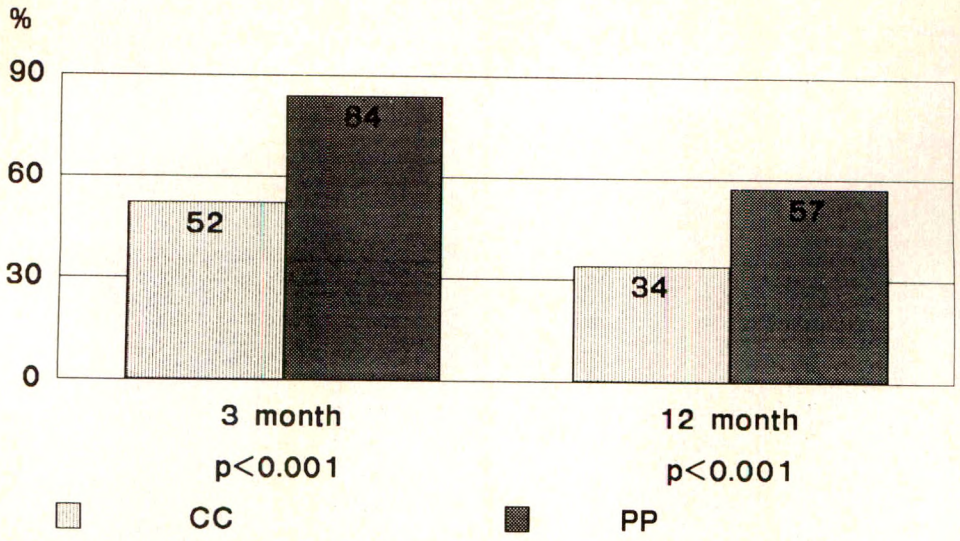

Fig. 2. Compliance at private practice *(PP)* and city clinic *(CC)* of all patients initiating either study oral contraceptive.

monophasic or triphasic pills (Table I). At 3 months of follow-up 181 patients (81%) returned, and 148 (66%) were classified as compliant with 132 (59%) still taking the pill. There was no significant difference in compliance as a result of the type of pill either for the total group or when stratified by primary care site (Fig. 1), but compliance was significantly different when city clinic patients were compared with private practice patients (Fig. 2). Overall, compliant patients were more likely to use contraception before starting the pill, to express more satisfaction with the pill, and to have fewer real and perceived side effects with the pill than were noncompliant patients (Table II).

At 12 months of follow-up (mean 12.7 ± 3.9), 141 (63%) patients returned for a visit, and only 99 (44%) patients were still classified as compliant, with 66 (29%) taking the pill. No significant difference in compliance was attributed to the type of pill in the total sample or when stratified by primary care site (Fig. 3), but compliance was again significantly different between the clinic sites (Fig. 2). Patients compliant at 12 months were older at entry (18.2 ± 2.2 vs 17.4 ± 2.0 years, $p = 0.0021$) than noncompliant patients. Compliant patients were less likely to be concerned about possible pregnancy, more satisfied with the pill, and less likely to experience nausea with the pill (Table III).

The demographic variables associated with compliance in the overall group were the same for the triphasic pill group alone at 3 and 12 months, except that older age ($p = 0.088$) and father's level of education ($p = 0.32$) did not reach the level of significance at 3 months of follow-up. Compliant triphasic patients at 3 months had the same significant associations as the overall group, except a marginally significant association with prior use of contraception ($p = 0.076$), lack of headache ($p = 0.069$), and lack of nausea ($p = 0.085$). At 12 months of follow-up, prior use of birth control ($p = 0.0027$) was significantly associated with compliance for triphasic patients.

There were significantly more complaints of overall side effects, breakthrough bleeding, and amenorrhea at 3 and 12 months of follow-up for the monophasic contraceptive pill compared with the triphasic pill (Table IV). Weight change for the two oral contraceptive pills was the same at 3 months; a marginally significant difference was noted at 12 months (Table V). No significant difference in pregnancy rates was noted between the triphasic and monophasic pill at 3 months (3 [3%] vs 2 [2%]; $p = 1.0$) or at 12 months (7 [6%] vs 9 [8%]; $p = 0.46$). All known pregnancies were among city clinic patients who stated that they had stopped the pills. At long-term follow-up, the overall pregnancy rate was 8.2 pregnancies per 100 person years, the rate for city clinic patients was 19.2 pregnancies per 100 person years, and the rate for noncompliant city clinic patients was 49.6 pregnancies per 100 person years.

Logistic regression analyses identified the city clinic site of initial visit as the strongest predictor of oral contraceptive noncompliance at 3 months ($p = 0.001$) and 12 months ($p = 0.0045$) of follow-up. Pill type had no significant impact on compliance. At 3 months of follow-up, overall side effects ($p = 0.012$) and breakthrough bleeding ($p = 0.0065$) were significant predictors of noncompliance. When all side effects were modeled together at 3 months, nausea ($p = 0.015$) and perceived weight gain ($p = 0.022$) were the only significant predictors. At 12 months of follow-up, only

nausea ($p = 0.0081$) was a significant predictor of noncompliance.

Comment

Many of the factors that have an impact on adolescents' compliance with oral contraceptives are sociodemographic and are associated with poverty and lack of life opportunities, which leads to a sense of low self-esteem and hopelessness.[3-11, 14] No significant change in compliance or in overall pill satisfaction between the triphasic and monophasic pills was noted. However, adolescents on the triphasic pill experienced fewer side effects, breakthrough bleeding, and pill amenorrhea. Whereas several real or perceived side effects did have an impact on compliance in the total population in this study, the differences in side effects as a result of the two different pills were not reflected in an overall difference in compliance in spite of the large numbers in this study with sufficient power to pick up a moderately small effect. Any impact of the reduced side effects was too small to detect or was counterbalanced by the effect of packaging or some other minor effect not measured.

Although one weakness of this comparison is that patients were recruited in two different time intervals, fortunately no intervening new publicity about oral contraceptives appeared in the lay press. In addition, there were no significant differences in initial demographics between the two groups, and the same demographic and follow-up variables were consistent predictors of compliance for the triphasic pill alone, as well as for the monophasic group.[3]

Anticipatory guidance should be targeted to the patient population. Adolescent girls are particularly concerned about weight gain[3] and should be told about the findings of no significant mean weight change with either contraceptive studied. Perception of weight gain can lead to discontinuance of oral contraceptives, and thus any concern should be followed by office mea-

surements of weight. During the provider's introduction of an oral contraceptive, reassurance and discussion of the management of breakthough bleeding and pill amenorrhea are essential. Nausea and other side effects require prompt attention to prevent the adolescent from discontinuing use. Verbal and written instructions are crucial.[3]

In adolescent patients at either site the poor long-term compliance is of concern. Adolescents who are at high risk for pregnancy must be seen at more frequent

intervals than adults. Reaching out to at-risk teens with school problems, parenting sibs, sexually transmitted diseases, and substance abuse is critical. As in our previous study,[3] all known pregnancies were among noncompliant city clinic patients. The lack of pregnancies among private practice patients likely reflects the greater use of backup methods and motivation to avoid pregnancy even when the oral contraceptive has been discontinued.[3] It is probable that additional adolescents in both groups missed pills during cycles but did not become pregnant. Self-report of overall compliance in taking the pill or stopping because of not needing contraception is at least a sufficient marker of efficacy because none of these compliant adolescents became pregnant.[3, 6] Adolescents may have continued to take oral contraceptives prescribed in other settings, and thus compliance may have been underestimated. Anticipatory guidance at the initial gynecologic visit should always include discussions of condoms for backup and for reducing exposure to sexually transmitted diseases.

Adolescent pregnancy and compliance with birth control methods continue to be a major issue for providers and society. Confidential services must be provided with careful discussions of the safety and side effects of oral contraceptives to optimize adolescents' compliance. Beyond what physicians can do in their offices, improvements are needed in the areas of governmental policy, welfare, job and educational opportunities, school-based clinics, preventative education, and peer counseling to reduce the impact of the sociodemographic inequalities and internal sense of hopelessness that contribute to adolescent pregnancy.

We thank Annette Luongo for data entry and Mary Aruda, RN, PNP, for her data collection and suggestions.

Prenatal ultrasonographic diagnosis of fetal scrotal inguinal hernia

Israel Meizner, MD, Arie Levy, MD, Miriam Katz, MD, Tzippi Simhon, and Marek Glezerman, MD

Beer-Sheva, Israel

Fetal scrotal inguinal hernia was diagnosed at 33 weeks of pregnancy by ultrasonographic examination. Moving, echo-free, cystlike structures representing peristalsis within trapped loops of bowel in an abnormally enlarged scrotum were the main ultrasonographic finding. The diagnosis was confirmed post partum, and surgery was successfully carried out 4 days after delivery. (AM J OBSTET GYNECOL 1992;166:907-9.)

Key words: Prenatal diagnosis, ultrasonography, inguinal hernia

The most common defect in the abdominal wall in infants and children is indirect inguinal hernia.[1] The early detection of this pathologic condition is extremely important because segments of bowel may become trapped in the hernia pouch, subsequently leading to partial or complete obstruction of the lumen. We report a case of scrotal inguinal hernia diagnosed at 33 weeks of gestation. To the best of our knowledge this is the first report in the English literature of in utero diagnosis of fetal inguinal hernia.

Case report

A 21-year-old-woman, gravida 0 para 0, was referred for ultrasonography at 33 weeks' gestation because the fundal height did not correspond to the dates. On ultrasonographic examination, a single vertex-presenting fetus was observed. Measurements of biparietal diameter, head circumference, abdominal circumference, and femur length (86 mm, 30.6 cm, 27.5 cm, and 65 mm, respectively) corresponded perfectly to the dates. No other fetal abnormalities were detected. The fetus was male, and a huge scrotum measuring 65 × 56 × 64 mm was observed (Fig. 1). The penis was pushed aside by the enlarged scrotum. The testicles were very close to each other. Small, fluid-filled, cystlike formations occupied a considerable part of the scrotum. These structures demonstrated obvious peristalsis and represented loops of small bowel trapped in the scrotum (Fig. 2).

On the basis of this observation scrotal inguinal hernia was diagnosed. No intraabdominal pathologic condition that would cause elevated pressure within the abdominal cavity was observed on repeated ultrasonographic examinations performed at 2-week intervals. No evidence of bowel obstruction was found in the repeated scans, and the patient was allowed to continue the pregnancy. Normal spontaneous delivery occurred at term, and a male infant weighing 3.4 kg was delivered vaginally.

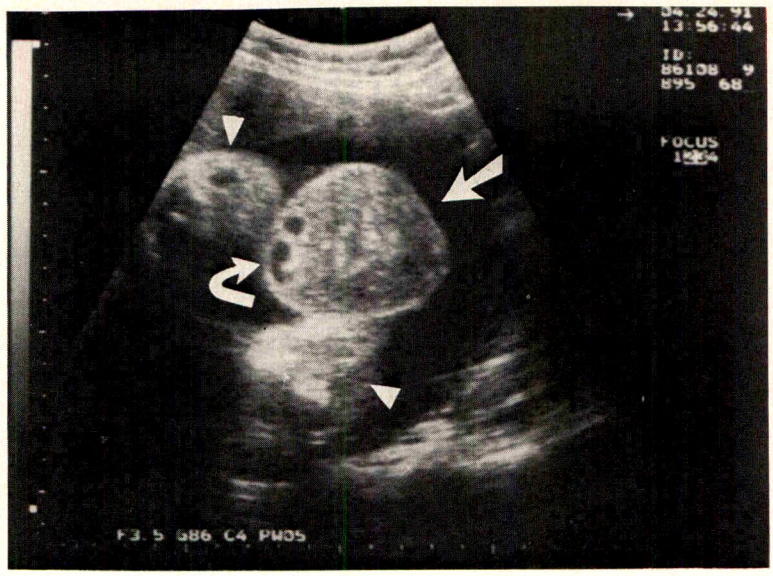

Fig. 1. Ultrasonographic scan at 36 weeks' gestation. Note huge scrotum *(arrow)* as compared with both thighs *(arrowheads)*. Loops of bowel are evident inside scrotum *(curved arrow)*.

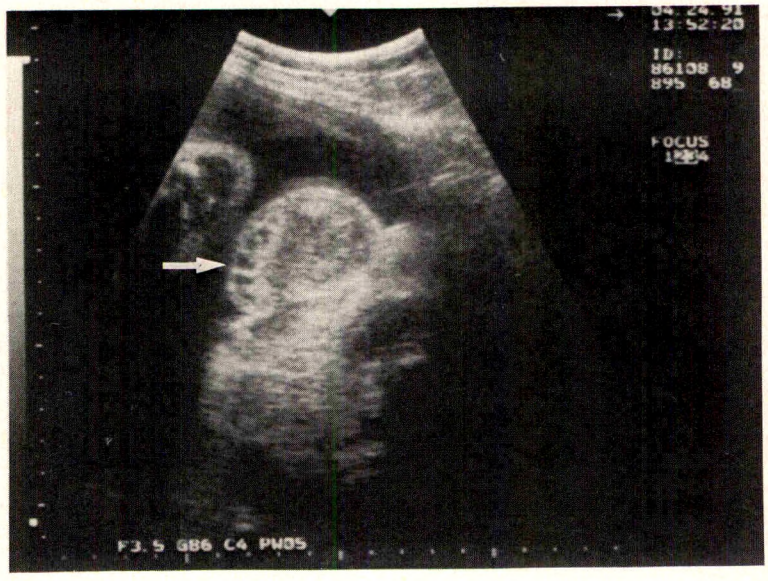

Fig. 2. Ultrasonogram illustrating trapped loop of bowel undergoing wave of peristalsis inside scrotum. *Arrow*, Loop of bowel.

The infant appeared normal except for a huge scrotum that was opaque to transmitted light (Fig. 3). Marked swelling was noted at the left external inguinal ring extending downward into the scrotum. On examination both testicles were palpated. A scrotal mass representing condensed bowel loops was also encountered. Reduction of the herniated bowel was carried out in the labor ward by the attending neonatologist; however, the herniated bowel reappeared when the infant started crying. At the end of the first week, surgical repair was successfully completed.

Comment

As the testes descend retroperitoneally from the genital ridge during the latter stages of embryonic life, the processus vaginalis, an outpouching of peritoneum, precedes the testes into the scrotum. The processus vaginalis originates at the internal ring, and as it leaves the canal at the external ring it turns inferiorly into the scrotum. The lower portion of this sac envelopes the testis to form the tunica vaginalis. The remainder of the sac normally atrophies before birth. The indirect

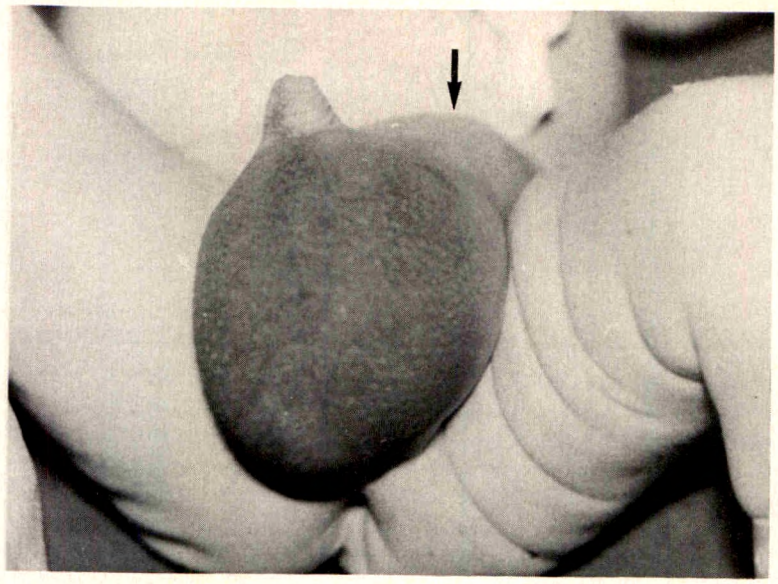

Fig. 3. Infant immediately after delivery. Huge scrotum is evident. Note bulging inguinal mass containing herniated small bowel *(arrow)*.

inguinal hernia results from a persistence of the processus vaginalis and manifests itself as a mass in the inguinal region when an abdominal viscus or peritoneal fluid is forced into it.

Although the hernial sac is present at birth, it usually remains empty for a variable period of time. By 2 or 3 months of age, when the infant is capable of increasing intraabdominal pressure, the sac may open and either fluid or abdominal content is forced into it. The hernial sac then appears as a swelling in the inguinal region, but it may extend in the male for a variable distance downward into the scrotum. In complicated cases a loop of bowel may become incarcerated in the sac.

The ultrasonographic markers for correct prenatal ultrasonographic diagnosis of inguinal scrotal hernia include the following: (1) huge scrotum, (2) cystic, fluid-containing structures inside the scrotum representing bowel loops, (3) evidence of peristalsis in the bowel, and (4) close relationship of both testicles. Because scrotal hernias in fetuses are rare, intraabdominal pathologic cause of elevation in abdominal pressure should be excluded first. Fetuses with multiple congenital anomalies, particularly those involving the lower abdomen, may display inguinal hernias as part of the anomaly complex.

An inguinal hernia extending into the scrotum should be carefully differentiated from a congenital hydrocele.[2] This differentiation is simpler in fetuses than in infants. In hydrocele the testicles are easily recognized because they are in clear peritoneal fluid, which gives a characteristically echo-free picture. This is not the case with scrotal hernia, in which the scrotum is filled with a partially echogenic mass with evident peristalsis.

Addendum

After submission of this article for publication, Ober et al.[3] reported a similar case.

Uterine and umbilical flow velocity waveforms in normotensive and hypertensive subjects during the angiotensin II sensitivity test

Risto U. Erkkola, MD, PhD, and Jouko P. Pirhonen, MD

Turku, Finland

The systemic and uterine circulatory effects of angiotensin II infusion in five normotensive and 10 hypertensive subjects at the end of the third trimester of gestation were studied. Color Doppler ultrasonography was used for investigating the systolic/diastolic ratios on flow velocity waveforms in the uterine and umbilical arteries. A significant increase was observed in the systolic/diastolic ratio in the uterine artery in both groups. In normotensive subjects a differential effect of angiotensin II on the systemic diastolic blood pressure and on the systolic/diastolic ratio was observed; the uterine circulation had a slower response and a faster recovery than the maternal diastolic blood pressure. In hypertensive subjects this relative refractoriness to angiotensin II was less marked; the increase in uterine vascular resistance was faster and the recovery slower than in the normotensive group. No changes in the systolic/diastolic ratio in the umbilical artery were observed in either group. These results indicate that the uterine circulation of normotensive subjects is remarkably more refractory to angiotensin II than the circulation of hypertensive subjects. (AM J OBSTET GYNECOL 1992;166:910-6.)

Key words: Angiotensin II sensitivity test, Doppler ultrasonography, flow velocity waveform, pregnancy-induced hypertension, umbilical artery, uterine artery

An increased peripheral sensitivity of blood vessels to vasopressor substances is characteristic of pregnancy-induced hypertension. During pregnancy the refractoriness to angiotensin II is lost several weeks before clinical hypertension can be detected.[1] On the basis of these findings, an angiotensin II sensitivity test has been designed to predict the development of pregnancy-induced hypertension.[1] Although the physiologic basis of the angiotensin II test has been well investigated,[2] emerging ultrasonographic techniques offer the opportunity for a more profound investigation of the effects of the test. In our earlier study we observed a differential effect of angiotensin II on systemic and uterine circulation during the angiotensin II test in normotensive subjects at 24 to 26 weeks' gestation; the uterine circulation had a slower response and a faster recovery than the systemic diastolic blood pressure.[3] This study was designed to compare the effects of the angiotensin II test on maternal and fetal circulation in normotensive and hypertensive subjects during the third trimester of pregnancy. As in the earlier study, we applied color Doppler ultrasonography for vessel localization and pulsatile Doppler ultrasonography for recording uterine and umbilical flow velocity waveforms.

Subjects and methods

Five normotensive healthy women with singleton pregnancies volunteered as a control group (group 1). The maternal age ranged from 22 to 31 years (mean 26.6 years) and weight from 69 to 87 kg (mean 79.0 kg); gestational ages ranged from 35 to 39 weeks (mean 37.2 weeks). The duration of pregnancy was ascertained by accurate menstrual history and a second-trimester ultrasonographic examination. Two patients were nulliparous and three patients were parous with uneventful previous pregnancies.

Group 2 consisted of 10 women with singleton pregnancies of 33 to 40 weeks' gestation (mean 37.0 weeks). The gestational age was estimated as described. The maternal age ranged from 17 to 34 years (mean 25.1 years) and weight from 64 to 87 kg (mean 78.9 kg). All subjects were nulliparous with no knowledge of a hypertensive disorder before pregnancy. Also all subjects were normotensive during the first and second trimesters of the pregnancy. The average duration of pregnancy at the time of the elevated blood pressure was 35.5 ± 2.3 weeks (mean ± SD) (range 31 to 39 weeks). All subjects were hospitalized because of a diastolic blood pressure >100 mm Hg on three or more measurements. After 2 to 4 days of hospital rest, the diastolic blood pressure still exceeded 100 mm Hg in all

cases. Six of the subjects had albuminuria (range 0.5 to 1.6 gm/L).

None of the subjects in either group used any medications except for iron supplementation. None were in labor or had uterine contractions during the investigation. All subjects gave written informed consent. The study protocol was approved by the Ethics Committee of the Turku University Hospital.

The angiotensin II sensitivity test was performed as previously described.[1, 3] The women were in the left lateral semirecumbent position in a quiet room. Maternal blood pressure and heart rate were automatically measured from the right arm at 1-minute intervals throughout the test by means of an oscillometer (sphygmomanometer, BP-203, Nippon Colin Co., Tokyo). An intravenous line for infusion was inserted in the left arm, and after the diastolic blood pressure had been stable for ≥20 minutes, the line was connected to an infusion pump with a syringe containing angiotensin II amide (1000 ng/ml in 0.9% sodium chloride solution, Hypertensin, Ciba-Geigy, Basel). The angiotensin II infusion was started at a rate of 1.5 ng/kg/min, and the dose rate was increased by 1.5 ng/kg/min at 4-minute intervals. Once a rise in diastolic blood pressure by 10 mm Hg and subsequently by 20 mm Hg was obtained and the rise was stable, the examinations for flow waveforms were performed. Thereafter the infusion was discontinued, and the maternal heart rate and blood pressure were recorded at 1-minute intervals during the 10-minute recovery period. The external fetal heart rate was continuously recorded with a Hewlett Packard model 8040 cardiotocograph (Hewlett-Packard, Böblingen, Germany).

Before the angiotensin II infusion was started, the flow velocity waveforms of the uterine and umbilical arteries were recorded by a color Doppler system with a 3.5 MHz transducer (model SSD 870, Aloka Co., Tokyo). A 100 Hz high-pass filter was used to remove signals from slow-moving tissues. In all cases the main branch of the uterine artery on the right side and the free-floating part of the umbilical artery were visualized easily with color, and the beam was directed to the vessel. Once 10 to 15 regular waveforms were recorded, the image was frozen and three waveforms from the uterine artery and four to five from the umbilical artery were manually analyzed; the maximum velocities during systole and diastole were obtained. Examinations of the umbilical artery were done only in the absence of fetal breathing or gross body movements. The peak-systolic and least-diastolic frequencies were measured and the systolic/diastolic ratio was calculated. The uterine artery flow velocity waveforms were obtained at the 10 and 20 mm Hg increments in maternal diastolic blood pressure and also at 1-minute intervals after the test until the systolic/diastolic ratio had returned to the initial level. The second Doppler examination of umbilical artery was made at the 20 mm Hg increment in maternal diastolic blood pressure. The correlation coefficient between repeated measurements of the uterine artery has been 0.91 (coefficient of variation ±2.5%) and for umbilical artery 0.97 (coefficient of variation ±2.0%).

Individual data were summarized as means and standard deviations. The blood pressure and systolic/diastolic ratio in the uterine artery were compared between the groups before the angiotensin II test by the Student *t* test for unpaired observations. Similarly, the heart rates and angiotensin II doses required for the 20 mm Hg pressure increase were compared in different groups by applying the Student *t* test for unpaired samples. The significance in the changes in the diastolic blood pressure, in the systolic/diastolic ratio of the uterine artery flow waveform velocity, and in the changes in the ratio of these parameters was tested by analysis of variance for repeated measurements with one between factor (group) and one within factor (time). When pooled orthogonal components showed nonsphericity, Greenhouse-Geisser adjusted probability values were used.[4] When a statistically significant group × time interaction or time effect was found, the analysis was continued by applying contrasts.

Results

In the beginning of the test, the diastolic blood pressure was 71 ± 8 mm Hg in group 1 and 97 ± 3 mm Hg in group 2 ($p < 0.001$). The baseline heart rates were 77 ± 11 and 82 ± 4 beats/min (not significant). At the peak of the diastolic blood pressure, they were 72 ± 10 and 75 ± 7 beats/min, respectively. The effective mean pressor dose of angiotensin II was significantly higher (11.9 ± 3.8 $ng/kg^{-1} \times min^{-1}$) in group 1 than in group 2 (7.1 ± 3.2 $ng/kg^{-1} \times min^{-1}$) ($p = 0.023$).

The systolic/diastolic ratio in the uterine artery at the beginning of the test was 1.59 ± 0.04 in group 1 and 1.84 ± 0.19 in group 2 ($p = 0.019$). After the rise in the diastolic blood pressure of 10 mm Hg, the systolic/diastolic ratios were similar (1.61 ± 0.05 and 1.85 ± 0.18). Once the increase by 20 mm Hg was reached, the systolic/diastolic ratio in both groups increased significantly ($p < 0.001$) to 1.91 ± 0.07 and to 2.27 ± 0.18, respectively. The mean fractional increases in systolic/diastolic ratio in the groups were not statistically different (20% ± 8% and 23% ± 7%, respectively).

The diastolic blood pressure decreased in both groups to the preinfusion level within 4 minutes (range 2 to 5 minutes) after the test. Fig. 1 shows the mean profile of the effect of angiotensin II infusion on the diastolic blood pressure and on the systolic/diastolic

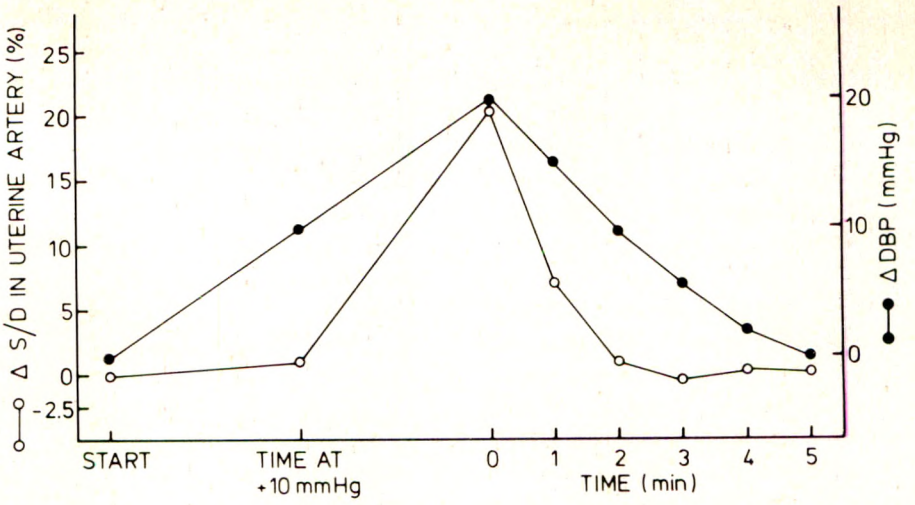

Fig. 1. Effect of angiotensin II sensitivity test on diastolic blood pressure (*DBP*, ●- - -● and systolic/diastolic ratio (*S/D*, ○- - -○) in flow velocity waveforms in uterine artery in normotensive subjects ($n = 5$).

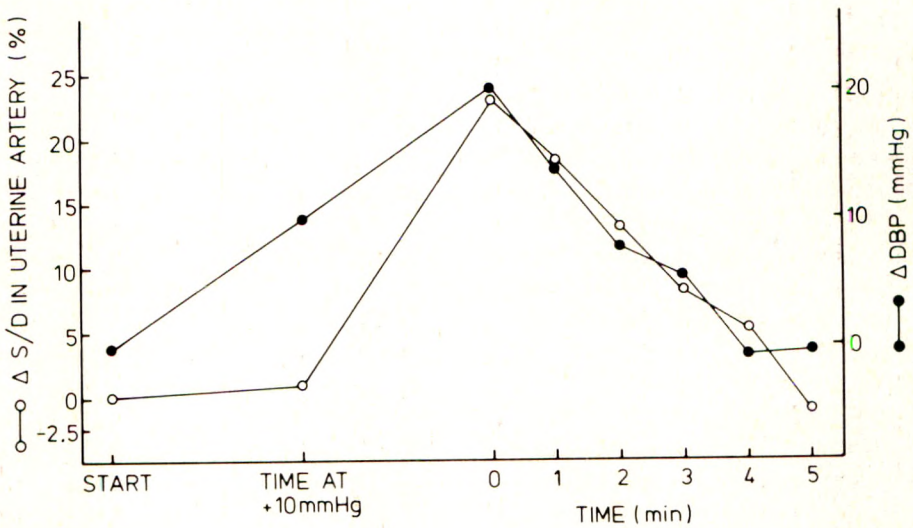

Fig. 2. Effects of angiotensin II sensitivity test on diastolic blood pressure (*DBP*, ●- - -●) and systolic/diastolic ratio (*S/D*, ○- - -○) in flow velocity waveforms in uterine artery in hypertensive subjects ($n = 10$).

ratio in uterine artery flow waveform velocity in group 1. Fig. 2 draws the mean profile of diastolic blood pressure and uterine artery flow velocity waveform in the group of hypertensive subjects (group 2). In normotensive women the response of the diastolic blood pressure and the systolic/diastolic ratio was significantly ($p < 0.001$) discordant (Table I). In contrast, in hypertensive women the declines of the diastolic blood pressure and systolic/diastolic ratio of the flow velocity waveform in the uterine artery were concordant (Table I). The comparison between the groups shows that the response of diastolic blood pressure to angiotensin II disappears at an equal rate in both groups (Table I). The recoveries of the increases in systolic/diastolic ratio in both groups were significantly faster in the normotensive group than in the hypertensive group (Table I). In the normotensive group the systolic/diastolic ratio in the uterine artery decreased faster than diastolic blood pressure and reached the initial level within 2 minutes in all subjects (Fig. 1). In group 2 the systolic/diastolic ratio in the uterine artery decreased to the preinfusion level within 4 minutes (range 3 to 5 minutes) (Fig. 2).

When the ratio of diastolic blood pressure to systolic/diastolic ratio is compared in the different groups, significant differences can be observed (Fig. 3, Table

Comparison was performed between every point of measurement against the initial value.

I). With an increase of diastolic blood pressure by 10 mm Hg, the ratio increased significantly ($p < 0.001$) and in a similar fashion in both groups. With an increase in diastolic blood pressure of 20 mm Hg, the ratio was still elevated in the normotensive group ($p = 0.009$); in the hypertensive group it returned toward the initial level ($p = 0.07$). Two ($p = 0.020$) and four ($p = 0.0016$) minutes after discontinuation of the infusion, the ratio between the diastolic blood pressure and the systolic/diastolic ratio was lower than the initial level in the hypertensive group, whereas in the normotensive group it was higher than initially until 4 minutes after cessation of the infusion.

When the groups were compared as a whole, the changes in diastolic blood pressure over time did not differ from each other ($p = 0.576$). Instead, both systolic/diastolic ratio ($p < 0.001$) and consequently the ratio of diastolic blood pressure to systolic/diastolic ratio ($p < 0.001$) differed significantly between the two groups (Table II).

Table II. Results of repeated measurements analysis of variance for diastolic blood pressure, systolic/diastolic ratio, and their ratio: Comparison of the groups

Variable	*Factor = Group*	*Factor = Time*	*Factor = Interaction*
Diastolic blood pressure			
F test	63.8	81.7	0.6
p Value	<0.001	<0.001	0.576
Systolic/diastolic			
F test	13.8	59.4	8.1
p Value	0.003	<0.001	<0.001
Ratio of diastolic blood pressure and systolic/diastolic ratio			
F test	1.3	10.0	8.9
p Value	0.273	<0.001	<0.001

The flow velocity waveform in the umbilical artery did not show any changes in either group. The mean systolic/diastolic ratios were 2.22 ± 0.09 (group 1) and 2.39 ± 0.21 (group 2) before angiotensin II infusion and 2.19 ± 0.16 and 2.39 ± 0.25, respectively, at the end of the test. The cardiotocograms showed, and the mothers felt, no uterine contractions during the tests. The fetal heart rate was normal and unaffected by the changes in the maternal diastolic blood pressure or by the changes in systolic/diastolic ratio in the uterine artery. Fetal movements were present in all cases at some time during the examination, and the fetal heart rate showed a reactive pattern.

Comment

The effects of angiotensin II on the systemic and uterine circulation during pregnancy have been investigated mainly in experimental animal models. By applying the Doppler method, it is possible noninvasively to study flow velocity waveforms whereby the end-diastolic frequencies of waveforms are likely to reflect the resistance of the downstream vascular bed. Very few direct comparisons between the actual flow and the simultaneous flow waveform velocity have been performed so far. In sheep fetuses the cotyledon resistance inversely correlates ($r = -0.94$) with diastolic/systolic ratio,[5] whereas systolic/diastolic ratio correlates well with umbilical vascular resistance ($r = 0.70$) and inversely with the umbilical artery flow ($r = -0.71$).[6] Also, in a computer model an increase in the uterine vascular bed resistance leads to a linear increase in the systolic/diastolic ratio.[7]

In animal studies a dual effect of angiotensin II on uterine blood flow has been observed. Although angiotensin II produces vasoconstriction in the uterine vasculature of pregnant sheep, the increase of the arterial perfusion pressure exceeds the effect of vasoconstriction, and consequently the uterine blood flow increases in the initial stage of infusion. When the uterine vascular resistance exceeds the effect of perfusion pressure, the uterine blood flow finally starts to decrease.[8, 9]

Our previous study group consisted of normotensive subjects, at 24 to 26 weeks' gestation,[3] which can now be compared with a group of normotensive subjects at 35 to 39 weeks. In the current group of normotensive subjects the diastolic blood pressure was slightly higher, the systolic/diastolic ratio slightly lower, and the dose of angiotensin II required in the test clearly lower than in the twenty-fifth week of pregnancy.[3] Very similar profiles in the diastolic blood pressure and systolic/diastolic ratio both in the initial phase and in the recovery phases were observed in both groups. In spite of the rise in the diastolic blood pressure by 10 mm Hg, the systolic/diastolic ratio barely changes and the ratio of diastolic blood pressure over the systolic/diastolic ratio increases significantly in both normotensive groups. This indicates a differential reaction in the systemic circulation and in the uterine circulation to angiotensin II. It also suggests that there is an increase in uterine blood flow in the earliest phase of infusion. Our results indicate that the human circulatory response to angiotensin II is similar to what has been observed in sheep models.

Another human study dealing with the flow velocity waveform measurements during the angiotensin test in human pregnancy is by Loquet et al.,[10] who studied normotensive women at 11 and 16 weeks of pregnancy. By using continuous Doppler, and in accordance with our study, they found an increasing pulsatility index in arcuate arteries with increasing diastolic blood pressure. Also in their study, in the early second trimester, the rise of the pulsatility index appears later than the blood pressure response.

In subjects with pregnancy-induced hypertension the pressor response to angiotensin II was stronger than in normotensive subjects. This is in accordance with earlier observations.[1, 11] Furthermore, the doses required for a rise in diastolic pressure of 20 mm Hg are very close to the doses at 37 weeks of gestation as reported by Gant et al.[1] The initial systolic/diastolic ratio in the uterine artery in hypertensive subjects was significantly higher than in normotensive subjects, reflecting an elevated resistance in the uterine vasculature in the pregnancy-induced hypertension.[12]

Very few studies are available on the uterine circulatory reactions to angiotensin II in hypertensive pregnancies. Lieb et al.[13] studied pregnant sheep with one-kidney hypertension. That model may differ from pregnancy-induced hypertension in humans, as the pressor effect of angiotensin II was actually less in hypertensive than in normotensive animals. Nevertheless, in both hypertensive and normotensive animals a differential effect on the systemic and uterine circulation was observed; with an increasing mean arterial blood pressure the uterine blood flow initially increased. By a totally different method, Gant et al.[14] observed a 13% decrease in the clearance rate of maternal plasma dehydroisoandrosterone sulfate during continuous infusion of angiotensin II. They suggested that this decrease could have occurred at least partly because of arteriolar vasoconstriction in uterine vasculature.

Our results show that the initial responses to angiotensin II in hypertensive and normotensive subjects were very similar. A relative refractoriness of the uterine vasculature to angiotensin II was observed in both groups at a 10 mm Hg rise in diastolic blood pressure. A difference between groups was observed when the diastolic blood pressure was raised by 20 mm Hg. In the group of normotensive subjects the ratio of diastolic blood pressure to the systolic/diastolic ratio was still significantly higher than the initial value; in the hypertensive group it had returned almost to the initial value. Hence it appears that the refractoriness of the uterine circulation and increased uterine blood flow prevailed longer in normotensive than in hypertensive subjects.

The same is also apparent from the recovery period; until the fourth minute of the recovery phase the ratio of diastolic blood pressure over the systolic/diastolic ratio was raised in the normotensive group. In contrast to this, the ratio in hypertensive group was similar to the initial level or significantly lowered during the entire recovery phase.

The reason for this different uterine vascular reactivity in normotensive and hypertensive subjects is open to speculation. Many observations indicate that vasodilating prostaglandins, prostacyclin in particular, may play an important role in attenuating the effect of angiotensin II.[15] In pregnancy-induced hypertension the elevated thromboxane A_2/prostacyclin ratio may interfere with vasodilation of the uterine vasculature.[16]

It has been suggested that high doses of angiotensin II given to the mother may have a direct or indirect depressing effect on fetal well-being.[17] Our previous[3] and current results show, however, that the angiotensin II sensitivity test is safe when performed in normotensive women between 24 and 40 weeks of gestation. It can also be safely carried out on subjects with moderate pregnancy-induced hypertension during the third trimester of pregnancy. An attenuated recovery of the uterine vascular reaction after angiotensin II infusion was, however, observed in hypertensive subjects. Although neither the flow velocity waveform nor fetal heart rate tracings showed deterioration of fetal well-being, it may, in fact, be compromised in women with more severe hypertension and an initially high systolic/diastolic ratio in the uterine artery flow.

In conclusion, the profile of systemic vascular reactivity to angiotensin II is similar in normotensive and hypertensive subjects, although the required dose of angiotensin II is higher in normotensive groups. The higher dose of angiotensin II needed in normotensive subjects may largely be due to relative refractoriness to angiotensin II in uterine vasculature, whereas the lowered dose requirement in hypertensive subjects reflects the loss of the refractoriness in uterine vasculature.

We thank Jouni Vuorinen, MSc, for assistance in statistical analysis of the data.

Patterns of failure of bulky-barrel carcinomas of the cervix

Deborah L. Coleman, MD,[a] Donald G. Gallup, MD,[a] Hugh D. Wolcott, MD,[b] Luther B. Otken, MD,[a] and Richard J. Stock, MD[b]

Augusta, Georgia, and Portsmouth, Virginia

OBJECTIVE(S): This retrospective study was conducted to analyze the hypothesis that radiation therapy followed by extrafascial hysterectomy would improve survival in patients with bulky-barrel cervical carcinomas.

STUDY DESIGN: Forty-three patients with bulky-barrel carcinomas of the cervix were treated over a 14-year period. The majority of these were treated with approximately 4000 cGY external beam, followed by brachytherapy, followed by extrafascial hysterectomy.

RESULTS: Forty-seven percent of all patients are dead of disease; 2.3% are alive with disease. Of the total patients, 35% had diseased paraaortic nodes, and 80% of these are dead of disease. Of the patients dead of disease, 80% had distant metastases. Delayed complications included: vesicovaginal fistulas (n = 3), surgery for bowel obstruction (n = 3), rectovaginal fistula (n = 1), and vaginal vault necrosis (n = 3).

CONCLUSION: These data do not support an improvement in survival of patients with bulky-barrel–shaped lesions treated with irradiation plus adjunctive hysterectomy. (Am J Obstet Gynecol 1992;166:916-20.)

Key words: Cervical cancer; bulky-barrel lesions; adjuvant hysterectomy, complications

Early stage cervical cancers (IB, IIA) have been treated, with equal success, by radical surgery or by radiation therapy, each with a 5-year survival of approximately 80% to 90%. In contrast, the large, bulky-barrel lesions of the cervix have been associated with a poorer prognosis and a higher percentage of central treatment failures. In 1969, Durrance et al.[1] were the first to advocate combination therapy, consisting of radiation followed by an extrafascial hysterectomy to decrease the rate of central recurrence and to remove inadequately treated disease. These authors reported a significant decrease in central recurrences in patients with endocervical disease that expanded the cervix. Nelson et al.,[2] emphasized that a simple extrafascial hysterectomy should be done with no attempt to remove a 1 to 2 cm vaginal cuff. Removing the cuff was felt to be particularly hazardous, because any additional dissection of the bladder might result in a fistula. They also emphasized that a 6-week interval was needed between completion of the brachytherapy and hysterectomy. During this time span, further treatment regression may result in an almost normal cervix. However, delay much beyond 6 weeks may allow hard fibrosis, characteristic of late irradiation changes and vascular compromise. O'Quinn et al.[3] later analyzed the M.D. Anderson experience and noted several delayed complications in 79 patients undergoing this combined therapy. Maruyama et al.[4] reported an 84% 5-year survival rate and a 78% 10-year survival rate in patients treated with combined therapy. They noted that pa-

tients with disease in the excised uterus had failure both in the pelvis and distantly. However, patients with negative specimens had failure in distant metastatic sites.

In a historic controlled study, Gallion et al.[5] compared 32 patients with stage IB barrel-shaped lesions treated by irradiation alone with 43 who were treated with irradiation followed by extrafascial hysterectomy. Recurrent cancer was noted in 47% of patients treated by irradiation alone, as compared with 16% of those treated with combined therapy. These authors reported no rectal or urinary tract fistulas in the patients treated with extrafascial hysterectomy. The validity of improved survival rates has been in doubt, because of the propensity of these tumors to spread to extrapelvic sites. Weems et al.[6] noted no difference in absolute survival in patients treated by irradiation alone or irradiation followed by hysterectomy. However, they noted a 2.5-fold increase in the percent of severe complications in the combined treatment group. Because of prior reports suggesting improved outcome in patients with bulky-barrel lesions, we began treating these patients with combined therapy in 1975.

The purpose of this article is to review the outcome of 43 patients with stage IB or IIA bulky-barrel lesions of the cervix, to analyze the failure sites, and to evaluate early and late complications in this select group of patients.

Material and methods

The clinical records from all cases with a diagnosis of carcinoma of the cervix at the Naval Hospital, Portsmouth, Virginia, from July 1975 through July 1984, and at the Medical College of Georgia, Augusta, Georgia, from July 1984 through July 1989, were reviewed. In all cases managed during this period of time the patients were examined by and operated on under the direction of one of the authors (D.G.G.). Follow-up information was obtained from tumor records and, when necessary, from phone calls and correspondence. All patients in this study were described at an informal or formal gynecologic-radiation-pathology tumor conference for final evaluation, review of pathologic diagnosis, and disposition. All pathologic specimens were reviewed by one of two pathologists (L.B.O. and R.L.S.) at their respective institutions. Recuts of slides were done when deemed necessary.

All patients underwent preoperative staging with an intravenous pyelogram, cystoscopy, and chest radiographs. Sixteen patients had a barium enema performed earlier in the study, and 10 patients had proctoscopy. Additionally, 35 patients underwent computed tomographic scan of the abdomen and pelvis with contrast. All patients were independently examined by at least two faculty physicians (gynecologists or radiation oncologists). Not all patients were examined while they were under anesthesia. If there was a disagreement in the examination, the lower stage (according to 1971 International Federation of Gynecology and Obstetrics classification) was assigned. Nine patients underwent a staging celiotomy before radiation. All nine had diseased paraaortic nodes and did not undergo hysterectomy. All patients in this study group retrospectively met current Gynecologic Oncology Group protocol requirements for bulky-barrel lesions. Patients either had an exophytic lesion with a diameter of ≥4 cm or had involvement of the cervix with cancer, resulting in expansion of the cervix and endocervix to 4 cm at the level of the internal os.

Patients who underwent hysterectomy were treated by a combination of irradiation and extrafascial hysterectomy. They received external beam therapy with 4000 to 4500 cGy followed by a cesium or radium insertion for 72 hours or a maximum of 5000 mg hours. Approximately 6 weeks after completion of the brachytherapy, patients underwent an extrafascial hysterectomy with bilateral salpingo-oophorectomy. Paraaortic nodes and pelvic nodes were assessed by careful palpation, and 77% of patients underwent paraaortic sampling. Patients with metastatic disease in paraaortic nodes were treated with 4500 cGy of extended field irradiation.

Results

During the period of study, 404 patients were treated for primary invasive cervical cancer. Forty-three patients (10.6%) had stage IB or IIA bulky-barrel lesions of the cervix. Five of the 43 were thought to have tumor encroaching on the vagina and were assigned as stage IIA.

The average age of the 43 patients was 45.7 years, with a range of 31 to 71. Twenty-nine percent were <40 years old, and 71% were <50. Seventy-one percent were white, 22% were black, and 7% were Malaysian. Most patients (89.5%) presented with some type of bleeding. None sought gynecologic consultation because of an abnormal cervical cytologic smear.

Cervical cytologic smears were suspicious for malignancy in 36 patients. Two had false-negative smears, and three did not have a smear. Three patients had a previous normal smear within a year before diagnosis, and seven, from 1 to 2 years. However, 16 patients had not had a smear for ≥5 years. All patients had normal pretreatment intravenous pyelograms and cystoscopic results. Only three patients with computed tomographic scans had suspicious nodes. One had a 2 cm pelvic node that was positive for cancer, as were the paraaortic nodes. The other two, both with suspicious 2 cm paraaortic nodes, had paraaortic node dissections with negative findings.

Lesion size or distension of the cervix was noted to be 4 cm in 19%, 5 cm in 37%, 6 cm in 17%, and >6 cm in 27%. When two patients alive with disease or

Table I. Survival for all patients*

Status	Patients	
	No.	%
No evidence of disease	21	48.8
Dead of disease	20	46.6
Alive with disease	1	2.3
Dead of intercurrent disease	1	2.3
TOTAL	43	100

All living patients had follow-up for at least 2 years.

Table II. Survival and cell type

Cell type	No. of patients	Dead of disease	
		No.	%
Squamous	29	10	34.5
Adenocarcinoma	9	5	55.5
Adenosquamous	4	4	100
Neuroendocrine	1	1	100
TOTAL	43	20	46.6

dead of intercurrent disease are excluded, no significant difference in survival was noted in those with lesions 4 to 5 cm in size (55%) as compared with those with lesions ≥6 cm (50%). Only six of the patients had an exophytic lesion with no apparent endocervical distension. The survival in these patients was similar to that of patients who had distension of the endocervix. Five of the 43 had clinical stage IIA assigned, and only one of these is alive.

None of the patients were lost to follow-up. All of the living patients have been evaluated for at least 24 months. Of the 43 patients, 47% are dead of disease (Table I). One patient is alive with disease. She has lung metastasis and is alive 36 months after diagnosis after cisplatin chemotherapy, lobectomy, and further chemotherapy. The patient dead of intercurrent disease died 50 months after original diagnosis of primary bronchogenic carcinoma of the lung. Tumors were histologically classified as squamous carcinoma (67%), adenocarcinoma (21%), adenosquamous carcinoma (10%), and neuroendocrine carcinoma (2%). Significantly, more patients with barrel lesions were dead of disease if the tumor had an adenomatous component, and no patients with adenosquamous cell tumor survived (Table II). Of the 10 patients dead of disease who had squamous tumor, the differentiation of the squamous cells did not affect survival.

Nine patients underwent a staging procedure and did not have hysterectomy. All nine had diseased paraaortic nodes. One of these patients is alive without evidence of disease 6 years later. She was treated with extended-field irradiation plus four cycles of vincristine, bleomycin, and cisplatin. Another of these nine had metastases to the lungs noted 2 years after extended-field irradiation. She was treated with cisplatin followed by mitomycin C and died 40 months after original diagnosis. Six patients had diseased paraaortic nodes resected at the time of hysterectomy. All were treated with extended-field paraaortic irradiation. Two of these are alive, 2 and 11 years after diagnosis. All but one of the patients with diseased paraaortic nodes had palpable nodes. Of the 43 patients, 15 (34.8%) had diseased paraaortic nodes, and 12 of these 15 (80%) are dead of disease.

Table III. Residual disease in excised cervix and survival

Amount	No. of patients	Dead of disease	
		No.	%
None*	15	3	20.0
Superficial Invasion	12	4	33.3
Deep invasion	7	5	71.4
TOTAL	34	12	35.3

*One patient is alive with metastatic disease, and one is dead of intercurrent disease.

Thirty-four of the 43 patients underwent hysterectomy after irradiation. Residual tumor deeply invading the excised, irradiated cervix was a poor prognostic factor, and 71.4% of such patients are dead of disease (Table III). If tumor was noted in vascular-like spaces in biopsy or hysterectomy specimens, 67% of the patients died, as compared with 31% without vascular-like invasion. Cell washings of the cul-de-sac were done in all 34 patients. Two (5.4%) had positive washings, and both died of disease.

Among patients dying of disease, 80% had distant metastases at the time of death (Table IV). Among patients dying of pelvic recurrence or pelvic recurrence plus distant metastases, 4 (36.4%) had initial recurrence on the pelvic sidewall, with no evidence of central disease. Distant metastases were documented by autopsy, radiography, computed tomography, and in one case by an upper gastrointestinal series showing involvement of the duodenum and proximal jejunum. Common sites of metastases included abdominal cavity, with or without small bowel involvement ($n = 9$); liver ($n = 7$); lung ($n = 7$); bone ($n = 2$); and supraclavicular nodes ($n = 3$). One patient each had metastases to the inguinal nodes, the heart, and the spleen. Of the 16 patients with distant metastases, 75% had previously noted diseased paraaortic nodes. Fifty-three percent of patients who died of disease did so within 12 months

Table IV. Patterns of recurrence in patients dead of disease

Site	Patients	
	No.	%
Distant metastases—all	16	80
Distant metastases alone	9	45
Distant and local metastases	7	35
Local alone	4	20
TOTAL	20	100

of the original diagnosis, and 77% died within 24 months.

Operative complications occurred in 9 of 43 patients (21%) undergoing any abdominal surgery, including 4 with wound infections, 3 with ileus, and 2 with pneumonia or atelectasis. However, 12 of the 34 patients eventually undergoing hysterectomy (35.3%) had significant delayed complications. All with delayed complications have no evidence of disease. Three were later operated on for small bowel obstruction, and two of these had small bowel resections. Three were treated conservatively for >8 months for vaginal vault necrosis. Vesicovaginal fistulas developed in 2, one had a rectovaginal fistula requiring colostomy, and one had a vesicovaginal fistula plus a rectovaginal fistula. Significant hemorrhagic cystitis developed in one patient, and another had peripheral neuropathy.

Comment

The mean age in this series was 45.7 years, similar to that reported in other series.[2, 3, 5] Blacks constituted 22% of the patients studied, which is a disproportionately lower proportion than the percentage of blacks in the patient population at the Medical College of Georgia. Frequent screening with cervical smears may have led to earlier diagnosis in some patients. It is noteworthy that 42% had not had a cervical cytologic smear in 5 years.

The overall survival of 80% to 90% in non-barrel, stage I to IIA cervical cancers treated with radical surgery or radiation alone is well known.[7, 8] However, Durrance et al.[1] and Gallion et al.[5] noted a significant reduction in survival rates to 53% and 64%, respectively, in comparably staged patients with the bulky-barrel–shaped lesions treated with irradiation alone. The addition of extrafascial hysterectomy to preoperative radiation has improved the survival rates, and in some series the survival rates are comparable to those of early stage carcinoma of the cervix[1, 2, 5, 9, 10] (Table V). In our series only 59% of patients are free of disease after combined treatment, significantly lower than the rates in most other reported series.

The survival for patients with adenosquamous cell lesions was dismal. We have previously reported a relatively poorer survival in patients with early stage adenocarcinoma,[11] and we separately reported a poor prognosis in patients with early stage adenosquamous cell carcinoma, independent of lesion size.[12] Russel et al.[9] also reported relatively more recurrences in patients with adenomatous-type lesions treated with combined modalities. In the current series no difference in survival was noted when different-sized lesions >4 cm were compared. Histologic examination of the hysterectomy specimens revealed residual tumor in 14 of 43 cases (33%) in the Kentucky series.[5] In our series residual tumor was found in 19 of 34 cases (56%). Twelve patients had superficial invasion, and seven patients had deep invasion. As expected, deeper invasion correlated with poorer prognosis. Russel et al.[9] also noted more recurrences if patients had residual tumor after preoperative irradiation.

Table V. Survival in patients treated by combined therapy

Nelson et al.[2] (1975)	50	37	74
Gallion et al.[5] (1985)	43	36	84
Russel et al.[9] (1987)	25	14	56
Tinga et al.[10] (1988)	20	16	80
Current series	34	20	59
TOTAL	211	152	72

The incidence of paraaortic lymph node metastases varies directly with tumor volume and has been reported to be as high as 20% in patients with stage IB bulky endophytic tumors.[13, 14] In our series the percentage of diseased paraaortic nodes was much higher, and these patients did poorly. Before any preoperative irradiation plan is instituted, strong consideration for surgical staging should be given in these high-risk patients.

In our series 45% of patients with recurrence had distant metastases alone, similar to the rate of Nelson et al.[2] (39%) and Gallion et al.[5] (38%). Additionally, we noted that 35% of patients had distant metastases plus pelvic recurrence. Gallion et al.[5] reported a pelvis-only recurrence rate of 13%, as compared with 46% for Nelson et al.[2] and 20% in our series. Note that among our patients with pelvic recurrence, four initially had recurrence on the sidewall. The high percentage of

patients described herein with recurrent disease outside the irradiated field is disturbing and should initiate trials of systemic therapy. Kim et al.[15] reported data evaluating the effect of preoperative chemotherapy on survival in patients with stage IB and IIB bulky tumors. The 54 patients first received initial combination chemotherapy of vinblastine, bleomycin, and cisplatin and later underwent radical hysterectomy with bilateral pelvic lymphadenectomy. The overall 2-year tumor-free survival rate was 94%. Of note, patients with lymph node involvement were treated with an additional three courses of chemotherapy, and patients with residual parametrial disease were treated with radiation therapy. In spite of the flaws of the study, their results are encouraging. Rettenmaier et al.[16] suggest an up-front surgical approach of radical hysterectomy with pelvic lymph node dissection, paraaortic node sampling, and tailoring postoperative radiation therapy to the extent of disease. Only 35% of the patients needed postoperative irradiation, and the projected 5-year survival rate for all patients was 79%.

Major complications for the combined approach have been reported by others. Nelson et al.[2] reported a major complication rate of 7.4% (7/95), including six fistulas and one small bowel obstruction. O'Quinn et al.[3] reported a major complication rate of 11%, including seven fistulas, one severe vault slough, and one small bowel obstruction. In our series the major complication rate is much higher (38%) and included three small bowel obstructions, three vaginal vault necroses, and four fistulas. To decrease the complications of rectovaginal or vesicovaginal fistulas, the insertion of an omental pedicle between the bladder and rectum, sutured to the vaginal apex, might improve the integrity of these local tissues.[17] Because of our noted complications of vesicovaginal fistulas, we drain the bladder 6 days after operation and prefer to use a suprapubic catheter.

We have noted a significant decrease in survival in patients with bulky-barrel lesions treated by combined therapy as compared with most other large series. The difference is probably best explained by the preponderance of patients dying of disease with tumor outside the irradiated field. Surgical staging should be strongly considered in patients with these bulky lesions. Because the vast majority of those dying of disease eventually have distant metastases, systemic treatment should be considered. Pilot studies are indicated, and randomized prospective studies should follow. Not only did we not note an improvement in survival in patients treated with combined therapy, we also found a relatively high rate of major complications. The benefits of combined therapy may not outweigh the risks.

Normal fetal Doppler inferior vena cava, transtricuspid, and umbilical artery flow velocity waveforms between 11 and 16 weeks' gestation

Juriy W. Wladimiroff, MD, PhD,[a] Tjeerd W.A. Huisman, MD,[a] Patricia A. Stewart, PhD,[a] and Th. Stijnen, PhD[b]

Rotterdam, The Netherlands

OBJECTIVES: Our objectives were to determine flow velocity waveform patterns in the fetal inferior vena cava and to relate these waveforms to transtricuspid and umbilical artery waveforms and fetal heart rate in early gestation.

STUDY DESIGN: Doppler waveforms were recorded in 40 normal fetuses at 11 to 16 weeks of gestation. Only transvaginal scanning was carried out at 11 to 12 weeks and only transabdominal scanning was used at 15 to 16 weeks.

RESULTS: The ratio of time velocity integrals of flow from the inferior vena cava during systole and early diastole, the percentage of reverse flow in this vessel, the pulsatility index from the umbilical artery, and the fetal heart rate were negatively correlated with gestational age. Peak E-wave and A-wave velocities and E/A ratios from the transtricuspid waveforms were positively correlated with gestational age.

CONCLUSION: Early normal pregnancies are associated with remarkable changes in fetal flow velocity waveforms at both the cardiac and the extracardiac level. (Am J Obstet Gynecol 1992;166:921-4.)

Key words: Doppler ultrasonography, fetal blood flow

Flow velocities in the inferior vena cava have been studied both in the adult[1] and in the fetus.[2] During the second half of normal pregnancy transabdominal Doppler ultrasonography has shown that waveforms from the fetal inferior vena cava are characterized by a two-component forward-flow pattern reflecting ventricular systole and early diastole (passive atrial filling) and a one-component reverse-flow pattern reflecting atrial contraction.[2] At the same time, flow velocity waveforms from the fetal internal carotid artery, descending aorta, and umbilical artery depict a low vascular resistance at the fetal cerebral trunk and umbilical-placental level.[3-5] In the growth-retarded fetus raised umbilical-placental vascular resistance[3-5] and increased reverse flow in the inferior vena cava[2] were established.

Transvaginal scanning greatly enhances the ultrasonographic image quality of the developing fetus. Recent studies with transvaginal Doppler ultrasonography at the cardiac[6] and extracardiac artery level[7] in normal late-first-trimester fetuses demonstrated flow velocity waveforms that are clearly different from those seen during the late second and third trimesters of pregnancy. In the umbilical artery end-diastolic velocities were nearly always absent. At the atrioventricular level peak E-wave velocities, representing early diastolic filling, were only 45% to 50% of peak A-wave velocities, representing atrial contraction. Because cardiac performance is also determined by preload, it was hypothesized that late-first-trimester fetuses would show inferior vena cava flow velocity waveforms that were different from those observed later in pregnancy.

The objective of the current study was to determine the flow velocity waveform patterns in the fetal inferior vena cava and to relate these waveforms to transtricuspid and umbilical artery waveforms and fetal heart rate (FHR) during late-first-trimester and early second-trimester pregnancies.

Material and methods

A total of 40 normal singleton pregnancies at 11 to 16 weeks of gestation (median 14 weeks) was studied. The protocol for the Doppler studies was approved by the hospital ethics review board. All pregnant women consented to participate in the study. Maternal age ranged between 18 and 37 years (median 28 years).

Ultrasonographic Doppler studies were performed with a Hitachi EUB 450 (Hitachi Medical Corporation, Tokyo). A combined transvaginal real-time and pulsed Doppler system with a carrier frequency of 3.5 MHz

(real-time) and 6.5 MHz (Doppler) or a combined transabdominal real-time and pulsed Doppler system with a carrier frequency of 3.5 MHz (real-time) and 3.0 MHz (Doppler) was used, depending on fetal size and position relative to the ultrasonographic probe. Both systems operate at a power output of <100 mW/cm^2 spatial peak temporal average in imaging and Doppler modes.

The pregnancy duration was determined from the last menstrual period and confirmed by ultrasonographic measurements of the crown-rump length (11 to 12 weeks) or the biparietal diameter (13 to 16 weeks). Each woman was included in the study once. Doppler studies were performed by one examiner (J.W.W.). Flow velocity waveforms from the inferior vena cava were obtained in a sagittal view that included the fetal right atrium, right ventricle, and ascending aorta.[2] The sample volume was positioned over the inferior vena cava immediately proximal to the right atrium. Transtricuspid flow velocity waveforms were recorded from the two-dimensional image in the four-chamber view.[8] The sample volume was placed immediately distal to the tricuspid valve. At both recording levels the angle between the Doppler cursor and the assumed direction of flow was always ≤ 20 degrees and the sample volume length 0.1 to 0.3 cm. The flow velocity waveform in the umbilical artery was obtained from a free-floating loop of the umbilical cord.[9] For all recordings the high-pass filter was set at 100 Hz.

All Doppler studies were performed with the woman in a semirecumbent position and during fetal apnea. The total examination time was limited to 15 minutes in each instance. All flow velocity waveforms were recorded on hard copies. A microcomputer (Olivetti M24, Olivetti B.V., Leiden, The Netherlands) linked to a Graphics tablet was used for analysis of the Doppler recordings. Waveform analysis in the inferior vena cava consisted of calculation of (1) the ratio between the time-velocity integral during systole and the time-velocity integral during early diastole and (2) the time-velocity integral during reverse flow (atrial contraction), which is expressed as a percentage of total forward flow during systole and early diastole (passive atrial filling).[2] Peak velocities at E wave (passive atrial filling) and A wave (atrial contraction) and E/A ratios were calculated from transtricuspid flow velocity waveforms. Waveform analysis in the umbilical artery consisted of calculation of the pulsatility index,[10] which is derived by dividing the difference between peak systolic and end-diastolic velocity by the averaged velocity over the entire cardiac cycle. At all three recording levels, an average of three consecutive flow velocity waveforms with the highest velocity and similar appearance was used to establish each value.

Linear regression analysis was used to compare flow velocity waveform parameters with gestational age. Partial correlation coefficients,[11] after gestational age was controlled for, were computed to assess the relationships between the different flow velocity waveform parameters and between each of these parameters and FHR. Partial correlation coefficients were used to avoid two parameters becoming artificially correlated when both were correlated with gestational age.

Results

Transvaginal scanning was carried out in all women at 11 to 12 weeks, in 50% of women at 13 weeks, and in 20% of women at 14 weeks of gestation. Transabdominal scanning was performed in the remaining 50% of women at 13 weeks, in 80% of women at 14 weeks, and in all women at 15 to 16 weeks of gestation. Technically acceptable waveforms were obtained from the fetal inferior vena cava in all 40 women, at umbilical artery level in 35 women (87.5%), and at tricuspid valve level in 31 women (77.5%). Recording failures were not confined to a particular gestational age. Fig. 1 represents flow velocity waveforms from all three recording levels at 11 and 16 weeks of gestation, respectively. A statistically significant negative correlation with gestational age was established for the ratio of time-velocity integrals of flow from the inferior vena cava during systole to time-velocity integrals of flow during early diastole ($r = -0.74$, $p < 0.0001$), the percentage of reverse flow in the inferior vena cava ($r = -0.80$, $p < 0.0001$), the pulsatility index from the umbilical artery ($r = -0.74$, $p < 0.0001$), and the FHR ($r = -0.66$; $p < 0.0001$). FHR varied between 170 and 180 beats/min at 11 weeks and between 140 and 150 beats/min at 16 weeks of gestation. End-diastolic flow velocities in the umbilical artery were absent in all cases at 11 to 12 weeks and in 54% of cases at 13 to 14 weeks. They were present in all cases at 15 to 16 weeks of gestation. A statistically significant positive correlation with gestational age was found for peak E-wave velocities ($r = +0.83$, $p < 0.0001$), peak A-wave velocities ($r = +0.73$, $p < 0.0001$), and E/A ratios ($r = +0.73$, $p < 0.0001$) from transtricuspid waveforms. No correlation existed between the different waveform parameters or between each of these waveform parameters and heart rate, when gestational age was controlled for.

Comment

Combined two-dimensional real-time and pulsed Doppler ultrasonography has been used to establish flow data in human fetuses under physiologic and pathophysiologic circumstances. To our knowledge the current study is a first effort to document changes in flow velocity waveform characteristics at fetal inferior vena cava and tricuspid valve level in late-first-trimester

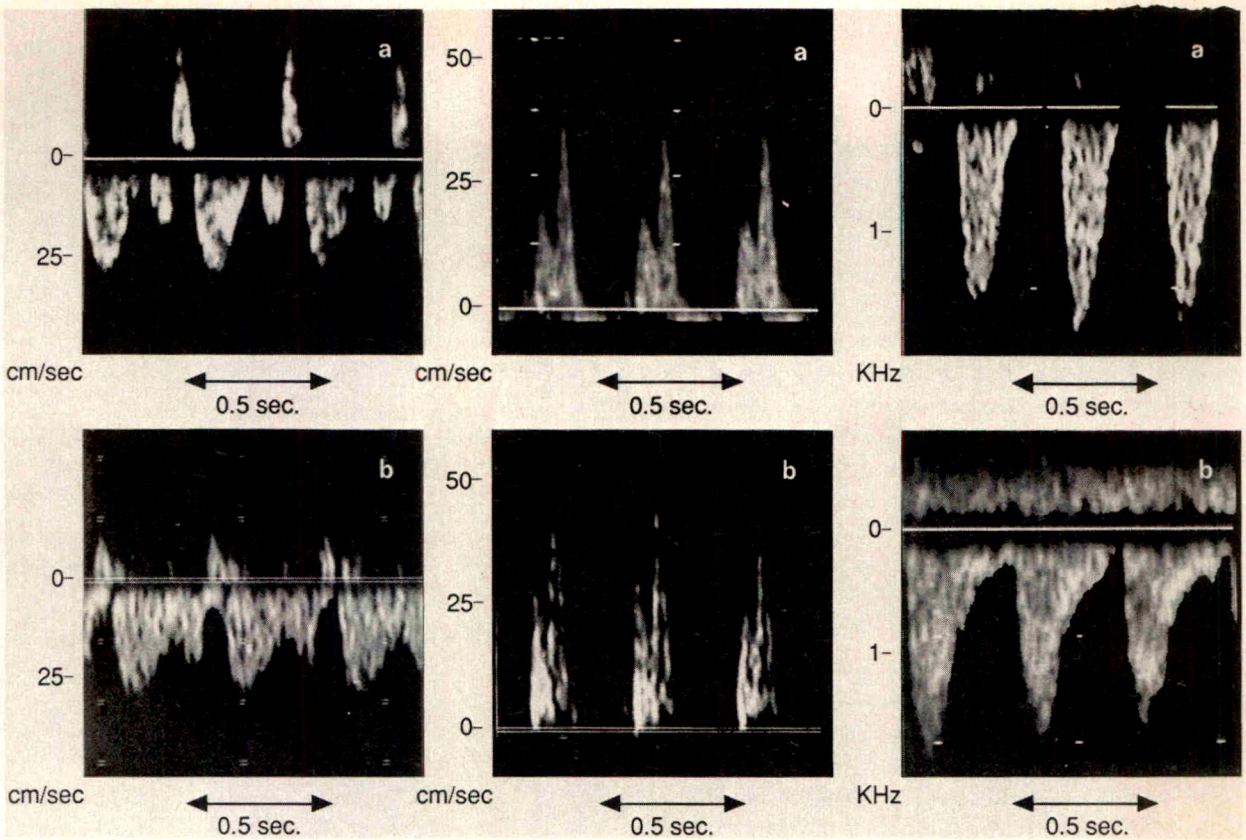

Fig. 1. Doppler flow velocity waveform tracings from inferior vena cava *(left panel)*, tricuspid valve *(center panel)*, and umbilical artery *(right panel)* at 11 weeks (*upper section*, **a**) and 16 weeks (*lower section*, **b**) of gestation.

and early second-trimester pregnancies. Transvaginal waveform recording became increasingly less successful after 12 weeks of gestation. This was mainly due to increasing fetal size resulting in large parts of the fetus becoming inaccessible to ultrasonographic imaging. For this reason transabdominal waveform recording was carried out in all cases after 14 weeks of gestation. Similar to those in late gestation, flow velocity waveforms from the fetal inferior vena cava in early pregnancy depict a two-component forward-flow pattern and a one-component reverse-flow pattern. Technically acceptable waveforms in this vessel were obtained in all instances, whereas this was not the case for waveform recordings at the other two scanning levels. This difference in recording rate was determined by the fact that the prime objective was to obtain acceptable waveforms from the fetal inferior vena cava. Because of the predetermined maximum study period of 15 minutes, this often resulted in less time being available for documentation of waveforms originating from the tricuspid valve level or umbilical artery.

Peak velocities at both E and A waves of transtricuspid waveforms display a marked rise with advancing gestational age, suggesting an increase in early diastolic atrial filling and active atrial contraction. This may be a result of raised cardiac compliance or increased ventricular relaxation rate. However, this cannot be substantiated because of lack of pressure data. At the same time there is a drop in ratios for time-velocity integrals of flow during systole to time-velocity integrals of flow during early diastole and a drop in percentage reverse flow in the fetal inferior vena cava. The lack of any relationship between inferior vena cava flow parameters and flow parameters originating from the other two measuring points, when standardized for gestational age, suggests a multifactorial cause of the observed venous waveform changes with advancing gestational age. Ventricular compliance, right-to-left atrial pressure differences, and cardiac afterload may play a role in this. Absolute values for percentage reverse flow in the fetal inferior vena cava at 11 to 12 weeks gestation are twice the values found at 16 weeks and four times the values established during late-third-trimester pregnancies.[12] Reed et al.[2] established that values for percentage reverse flow are the lowest in the heart rate range between 120 and 160 beats/min, which are nor-

mal rates for late-second-trimester and third-trimester pregnancies. During bradycardia (<120 beats/min) and tachycardia (>160 beats/min), a rise in percentage reverse flow in the inferior vena cava was noted, suggesting less optimal atrial contraction under these circumstances. In this study FHR was subject to a marked reduction, which has been attributed mainly to maturation of the parasympathetic system.[13] The absence of a correlation between heart rate and percentage reverse flow in the inferior vena cava suggests that heart rate is independent of the percentage reverse flow changes observed between 11 and 16 weeks of gestation. At the same time a marked reduction in pulsatility index in the umbilical artery was observed. This reduction was mainly determined by the appearance of end-diastolic flow, as from 13 to 14 weeks. This may be explained by a drop in umbilical-placental vascular resistance. In favor of this supposition is that this development coincides with a resurgence of endovascular trophoblast migration with a second wave of cells moving into intramyometrial layers of the spiral arteries. This will result in destruction of the medial musculoelastic tissue in the vessel wall and conversion of the thick-walled muscular spiral arteries into flaccid saclike uteroplacental vessels.[14, 15] In this way the placenta establishes its own low-pressure, high-conductance vascular systems, which are necessary to accommodate the increased blood flow to the developing fetus. It has also been demonstrated that this intravascular invasion by extravillous trophoblast is hampered in women who at a later stage have preeclampsia or intrauterine growth retardation.[16, 17] If there is a relationship between the aforementioned normal vascular changes at the placental level and the observed changes in fetal blood flow velocity waveforms in late-first-trimester pregnancies, then it would be of interest to examine fetal flow velocity waveforms in those early pregnancies that are at increased risk of subsequent development of preeclampsia or intrauterine growth retardation. Significant flow velocity waveform changes have been observed at umbilical-placental, cardiac, and cerebral levels under these pathologic circumstances in late gestation.[18]

It can be concluded from the current study that late-first-trimester and early second-trimester normal pregnancies are associated with remarkable changes in fetal flow velocity waveforms at both cardiac and extracardiac levels. These changes are independent of the reduction in FHR observed at this stage of early pregnancy. The reduction in inferior vena cava flow reversal may be a result of raised ventricular compliance or increased ventricular relaxation rate.

Maternal glucose intolerance and the subcutaneous terbutaline pump

Connie Lindenbaum, MD, Jack Ludmir, MD, Frann B. Teplick, MSN, RNC, Arnold W. Cohen, MD, and Philip Samuels, MD

Philadelphia, Pennsylvania

OBJECTIVE: Our hypothesis was that use of the subcutaneous terbutaline pump does not affect maternal glucose tolerance.

STUDY DESIGN: With the 1-hour glucose tolerance test, we examined the incidence of glucose intolerance in 37 patients using the pump compared with that of 54 patients receiving oral terbutaline and 634 control subjects without risk factors for gestational diabetes. The frequency of gestational diabetes and the need for insulin to maintain glycemic control were subjected to χ^2 analysis.

RESULTS: The incidence of gestational diabetes was 6% in the control subjects, 5% in patients using the pump ($p = 0.8$), and 11% in those on the oral therapy regimen ($p = 0.4$). A total of 8% of controls who had gestational diabetes required both insulin and diet, compared with 100% using the pump ($p < 0.01$) and 50% on the oral terbutaline regimen ($p = 0.03$).

CONCLUSION: The incidence of gestational diabetes is not increased in patients receiving terbutaline via the subcutaneous pump. The use of terbutaline by any route significantly increases the need for insulin to achieve glycemic control. (Am J Obstet Gynecol 1992;166:925-8.)

Key words: Terbutaline, tocolytics, glucose intolerance, premature labor

Premature labor and delivery continue to contribute significantly to perinatal morbidity and mortality. The β-adrenergic receptor agonist class of tocolytic agents has long been used in the treatment of premature labor. Lack of pure β_2-adrenergic receptor selectivity results in many of the side effects often encountered in patients taking these medications. The long-term use of oral terbutaline in the treatment of preterm labor has been reported to result in maternal glucose intolerance.[1, 2] The subcutaneous terbutaline pump as described by Lam et al.[3] is a relatively new tocolytic modality that provides a continuous low-dose infusion of terbutaline, augmented with intermittent higher-dose boluses. The effect of this delivery system on glucose homeostasis has not been studied; therefore we examined the development of gestational diabetes in patients receiving subcutaneous terbutaline therapy.

Material and methods

All patients enrolled in this study received follow-up by the Division of Maternal-Fetal Medicine of the Hospital of the University of Pennsylvania. This study was approved by the Institutional Review Board of the University of Pennsylvania Medical Center. The study group included 91 consecutive private patients over a 24-month period between 26 and 36 weeks' gestation who were admitted to the labor floor with a diagnosis of premature labor. This diagnosis was based on documented cervical change or six or more uterine contractions per hour that were unresponsive to bed rest and intravenous hydration. The control group consisted of 634 consecutive patients whose pregnancies were uncomplicated by premature labor and with a gestational age at delivery ≥37 weeks. Patients with a history of pregestational or gestational diabetes, macrosomia, current steroid therapy, or multiple gestation were excluded from the study.

Study patients who required <24 hours of intravenous tocolysis with magnesium sulfate or ritodrine were subsequently placed on a regimen of oral therapy with 5 mg terbutaline every 4 hours. Patients who required >24 hours of intravenous tocolysis, multiple courses of intravenous tocolysis, or multiple-agent therapy were placed on the subcutaneous terbutaline pump (Model 404 SP, MiniMed Technologies, Sylmar, Calif.). The initial basal rate of delivery of terbutaline was calculated on the basis of pharmacokinetic parameters, including surface area, bioavailability, volume of distribution, clearance, elimination, and drug half-life.[4]

Both study and control patients were screened for glucose intolerance at 24 to 28 weeks' gestation with a standard 50 gm glucose load. All patients on a terbutaline regimen, both oral, and pump infusion, had evidence of a normal 1-hour oral glucose tolerance test

NS, Not significant.

(GTT) before inclusion in the study. Patients receiving terbutaline were also tested with a 50 gm oral GTT 72 hours after initiation of therapy. Screening for gestational diabetes was continued in patients receiving oral therapy with a postprandial capillary glucose fingerstick every 1 to 2 weeks. Patients on the subcutaneous pump regimen were evaluated weekly in the same manner. Any 2-hour postprandial capillary glucose value >130 mg/dl was followed with a 50 gm oral GTT screen. All patients with an abnormal oral GTT result, defined as a serum glucose level >135 mg/dl, underwent a 3-hour GTT as described by O'Sullivan and Mahan.[5] The diagnosis of gestational diabetes was made when two or more abnormal values were found. All patients with gestational diabetes, in whom adequate glycemic control was not achieved with diet (fasting blood glucose level >100 mg/dl and/or 2-hour postprandial blood glucose level >120 mg/dl) were also treated with insulin. Statistical evaluation of the data obtained was performed with the Student t test, χ^2, and Fisher's exact test.

Results

Ninety-one consecutive patients whose pregnancies were complicated by premature labor were enrolled in the study. There was no difference in predisposing factors to gestational diabetes in any of the groups. In the control group the mean maternal age at delivery was 33.6 ± 4.8 years (mean ± SD), compared with 32.8 ± 2.8 years in those receiving pump therapy and 32.1 ± 2.7 years for those receiving oral therapy (Table I). The subcutaneous pump was instituted in 37 patients at a mean gestational age of 30.1 ± 2.1 weeks and discontinued at a mean of 35.9 ± 1.1 weeks. The mean gestational age at delivery was 37.2 weeks and average birth weight was 3228.6 ± 583.5 gm. The mean initial basal infusion rate was 0.056 ± 0.008 mg/hr. The mean final basal rate was 0.074 ± 0.02 mg/hr (Fig. 1). In addition, each patient had six to 10 scheduled or emergent daily boluses, each consisting of 0.25 mg terbutaline.

Fifty-four patients had successful management with oral terbutaline. The mean gestational ages at the start and cessation of oral therapy were 28.9 ± 1.96 and 36.2 ± 0.87 weeks, respectively. The mean gestational age at delivery was 37.9 ± 1.3 weeks with mean birth weight of 3017.3 ± 303.3 gm. The mean age at delivery for the control group was 38.2 ± 2.8 weeks with mean birth weight of 3325.4 ± 487.2 gm.

Seven patients (19%) receiving terbutaline pump therapy had an abnormal 1-hour GTT result compared with 114 patients (18%) in the control population (p = 0.9) and 14 patients (26%) receiving oral terbutaline (p = 0.6) (Table II). There was not a significant difference when those receiving oral therapy were compared with the control group (p = 0.2, χ^2).

Approximately 75% of the abnormal 1-hour GTT results in the terbutaline-treated patients occurred 72 hours after the medication was started. Abnormalities in an additional 25% were diagnosed within 2 weeks of initiation of therapy. In all patients with development of glucose intolerance, this occurred before 35 weeks' gestational age. An abnormal 3-hour GTT result was observed in two patients receiving subcutaneous terbutaline therapy (5%) compared with 36 patients (6%) in the control population (p = 0.8, χ^2) and six patients (11%) receiving oral medication (p = 0.4, χ^2). Although gestational diabetes developed in nearly twice the percentage of patients receiving oral therapy when compared with the controls, this difference was not significant (p = 0.1, χ^2).

The incidence of macrosomia in the controls with gestational diabetes was 5%. There were no cases of macrosomia in either group treated with terbutaline.

The treatment modalities needed to achieve adequate glycemic control in all patients are described in Table III. Both of the patients receiving subcutaneous terbutaline infusion who had gestational diabetes required insulin, compared with 8% in the control group

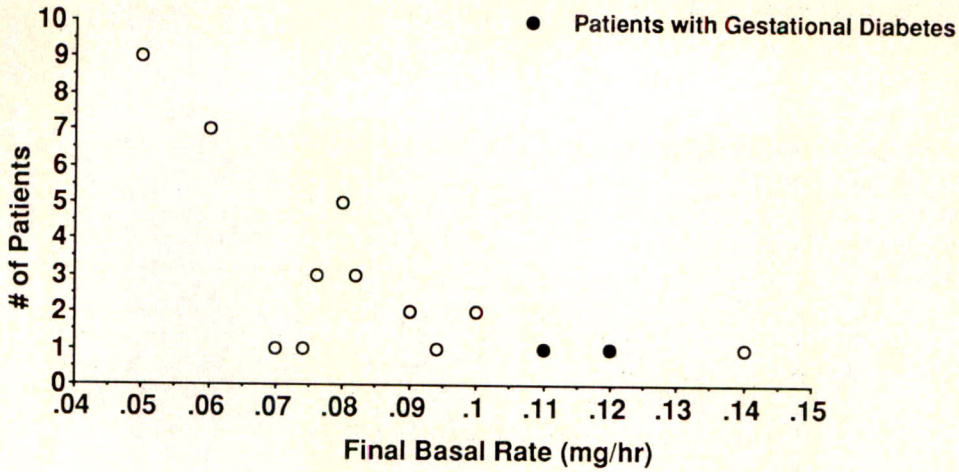

Fig. 1. Final terbutaline basal rate infusion.

($p < 0.01$, χ^2). A significant difference was also noted when those patients receiving oral therapy were compared with the control population ($p = 0.03$, χ^2).

Comment

The β-sympathomimetics are among the most common tocolytic agents used in the management of preterm labor. Long-term terbutaline use in pregnancy has been associated with a variety of maternal side effects, including electrolyte imbalance[6] and cardiovascular changes.[7] The development of tachyphylaxis with long-term terbutaline therapy is well documented.[8, 9] Several studies have indicated an association between terbutaline and the development of maternal glucose intolerance.[1, 2] The β-adrenergic receptor agonists have been shown to stimulate glucagon production by the pancreas, as well as increase gluconeogenesis and glycogenolysis.[10]

We did not find a statistically significant difference in the incidence of abnormal 1-hour screening with 50 gm of glucose between any of the groups either at initial evaluation or on start of therapy. There was no significant difference noted in the incidence of gestational diabetes when patients on the terbutaline pump regimen were compared with the control population or to those receiving oral therapy. Given the 80% sensitivity of the 1-hour 50 gm glucose screen,[11] it is possible that gestational diabetes would have developed in seven additional patients in the total population. It is unlikely that all would have come from the group with preterm labor who required terbutaline therapy.

Contrary to previous studies, we did not find a significant difference in glucose intolerance when patients receiving oral medication were compared with the control group ($p = 0.1$). The biggest difference between our study and the others is that all of the terbutaline-treated patients in our population had a previously normal 1-hour GTT result. Since the terbutaline-treated patients studied by Main et al.[1] and Angel et al.[2] were not all prescreened for glucose intolerance, the larger number of patients with an abnormal GTT result may include those patients who were destined to have glucose intolerance even without the added stress of a β-sympathomimetic. Our incidence of gestational diabetes in those patients receiving oral terbutaline (11%) agrees quite well with that found by Angel et al.[2] (11.6%). Main et al.[1] did describe nine patients who had normal glucose test results before treatment with terbutaline. We found that 6 of 54, or 1 of 9 patients receiving oral terbutaline, had gestational diabetes when compared with 2 of 9 patients in the prior study by Main et al.[1] It may be that the smaller numbers involved in these studies makes this difference appear greater than it really is.

The difference between oral and subcutaneous terbutaline may reflect the difference in dosing between the two tocolytic modalities. Lam et al.[3] have determined that a very low continuous basal infusion rate of 0.05 mg/hr will suppress uterine contractility. By using the subcutaneous pump, each patient receives a total daily dose of ≤3 mg/day compared with an oral dose

Table III. Methods of glycemic control in gestational diabetes

	Insulin vs diet				
	Diet		*Diet and insulin*		*Total*
	No.	*%*	*No.*	*%*	*No.*
Control	33	92	3	8	36
Oral	3	50	3	50*	6
Pump	0	0	2	100†	2

*$p < 0.05$, oral versus control (χ^2).

†$p < 0.01$, pump versus control; p = not significant, pump versus oral (Fisher's exact test).

of at least 30 mg/day. There are, of course, different absorptions with the two routes of administration, and therapeutic serum terbutaline levels have not yet been determined for the two groups. It has been postulated that the lower basal concentration of terbutaline supplemented by intermittent boluses can decrease the tachyphylaxis noted with the higher oral doses. In addition, the lower daily terbutaline dose given with the pump may result in less maternal gluconeogenesis and glycogenolysis, resulting in a lower incidence of carbohydrate intolerance. The two patients with development of gestational diabetes were maintained at a basal rate that was higher than average (Fig. 1).

An interesting finding was the significant difference in the need for insulin therapy to achieve adequate glycemic control in patients receiving terbutaline therapy when compared with controls. Main et al.[1] have previously described an increased need for insulin in patients receiving oral terbutaline therapy. Although our data indicate that this may also be true for patients using the terbutaline pump, many more patients will need to be observed for confirmation. The effect of the β-sympathomimetics may cause a more profound derangement of glucose homeostasis than that seen in idiopathic gestational diabetes.

In summary, the incidence of maternal glucose intolerance does not appear to be increased in those patients using the subcutaneous terbutaline pump even though testing is carried out more frequently after medication is started. However, the use of terbutaline, both orally and with the pump, appears to increase the need for insulin in those patients with development of gestational diabetes. Although the development of glucose intolerance in terbutaline-treated patients does not appear to be statistically different, this should not imply that there is not a clinical significance. The 5% to 10% incidence of gestational diabetes in those patients suggests that frequent surveillance of glucose tolerance, even in those previously tested, is recommended when they are receiving any form of terbutaline therapy.

Hydrops fetalis associated with congenital myotonic dystrophy

Ashraf M. Afifi, MD, Asha Rijhsinghani Bhatia, MD, and Fabian Eyal, MD
Baltimore, Maryland

We report a case of congenital myotonic dystrophy in a newborn infant who presented with hydrops fatalis. Clinical features were hypotonia, generalized edema, pleural effusion, respiratory distress, scalp hematomas, and tented mouth facies. Review of literature shows that congenital myotonic dystrophy is not a rare cause of nonimmune hydrops fetalis as previously thought. (Am J Obstet Gynecol 1992;166: 929-30.)

Key words: Nonimmune hydrops fetalis, congenital myotonic dystrophy

Various maternal and fetal conditions are associated with nonimmune hydrops fetalis. Failure to identify a causative agent remains a frequent dilemma because up to 30% of cases are called "idiopathic."

Congenital myotonic dystrophy is an autosomal-dominant muscle disorder that is rarely included among conditions associated with nonimmune hydrops fetalis. This report describes a case of congenital myotonic dystrophy presenting as fetal hydrops.

Case report

A 2760 gm, female infant was born at 36 weeks' gestation to a 33-year-old multigravid mother with type A, Rh-positive blood. The mother had a history of slowly progressive lower-extremity weakness for the past few years. There was no family history of neuromuscular diseases. Previous pregnancies were uneventful and resulted in two healthy male children. The current pregnancy was complicated by worsening muscle weakness and progressive third-trimester polyhydramnios. The infant was delivered by cesarean section because of breech presentation. Post partum the mother had respiratory failure and required mechanical ventilation for a few days. The infant had Apgar scores of 2 and 5 at 1 and 5 minutes. Immediate resuscitation was required with intubation for poor respiratory effort. The infant remained severely hypotonic and continued to require mechanical ventilation. Generalized body edema was seen more extensively over the head and neck area. A "tented-shape" mouth was noted. Chest radiography revealed a right-sided pleural effusion and thin gracile ribs. Extensive scalp hematoma with no evidence of blood dyscrasia developed in the second week of life. Subsequently, edema and pleural effusion resolved and she was weaned from mechanical ventilatory support by 3 weeks of age. Her initial feeding difficulty slowly improved and she was feeding normally by the time of discharge home at 2 months of age.

The infant's blood type was A, Rh-positive and Coombs test negative. Karyotype was normal. A workup for congenital infection (TORCH [toxoplasmosis, rubella, cytomegalovirus, and herpes simplex] and parvovirus) was negative. Urine and serum screen for metabolic diseases gave normal results. The serum creatine phosphokinase level was within the normal range. Initial chest sonogram showed a right pleural effusion and a poorly moving and elevated right hemidiaphragm. The diagnosis of congenital muscular dystrophy was suspected by the characteristic maternal myopathic facies and myotonic grip. The mother's diagnosis was confirmed by neurologic consultation and abnormal results of electromyographic studies.

Comment

Congenital myotonic dystrophy is rarely listed among the conditions associated with nonimmune hydrops fetalis. One recent study mentioned one case among 900 patients with nonimmune hydrops fetalis.[1] However, in the pediatric literature we could identify at least 10 cases of congenital myotonic dystrophy with hydropic features.[2-4]

Pregnancy with an affected infant is often complicated by polyhydramnios, decreased fetal activity, breech presentation, and prematurity. A spectrum of neonatal presentations with congenital myotonic dystrophy may range from the fetus who is lost in early abortion, through the preterm baby who dies soon after birth, to the term asymptomatic infant. Early neonatal diagnosis of congenital myotonic dystrophy is difficult and many affected infants may die early in life before the diagnosis can be made. In addition, clinical presentation is variable and nonspecific, and severely affected babies can be misdiagnosed as having perinatal asphyxia.

Congenital myotonic dystrophy is a challenging di-

agnosis that can be suggested by careful clinical evaluation of the mother and her newborn. In fully expressed disease the mother has a characteristic myopathic facies with hollow temples and myotonic grip. On the other hand, the mother may be so mildly affected that she is unaware of the disease. A negative family history does not rule out the possibility. Both muscle biopsy and electromyography give only suggestive evidence, and necropsy examination is nonspecific.

Recently, localization of the congenital myotonic dystrophy gene on chromosome 19 with tightly linked deoxyribonucleic acid probes has facilitated prenatal diagnosis.

Awareness of the association between congenital myotonic dystrophy and nonimmune hydrops fetalis is important to reduce further the proportion of idiopathic nonimmune hydrops fetalis because congenital myotonic dystrophy might be a more frequent etiologic factor than previously thought.

Vaginal injury resulting from sliding down a water chute

Jacob Niv, MD, Joseph B. Lessing, MD, Joseph Hartuv, MD, and M. Reuben Peyser, MD
Tel Aviv, Israel

A 27-year-old woman was admitted to the hospital because of profuse vaginal bleeding from a vaginal laceration caused by the impact of water to the perineum after sliding down a water chute. At the time of the accident the patient was using a vaginal tampon. The potential mechanism for this trauma is discussed. (Am J Obstet Gynecol 1992;166:930-1.)

Key words: Vaginal trauma, water chute

A case of profuse vaginal bleeding caused by a slide down a water chute is described.

Case report

A 27-year-old healthy woman, gravida 1, para 1, was initially seen at the emergency department with massive vaginal bleeding after trauma to the lower back and vulva. This occurred when she hit the water after sliding down a water chute.

On admission the patient was conscious, pale, and had tachycardia to 120 beats/min.

From the Department of Obstetrics and Gynecology "A," Tel-Aviv Sourasky Medical Center, Hakirya Maternity Hospital, Sackler Faculty of Medicine, Tel-Aviv University.
Received for publication August 20, 1991; revised October 17, 1991; accepted October 31, 1991.
Reprint requests: Reuben M. Peyser, MD, Department of Obstetrics and Gynecology "A," Serlin Maternity Hospital, Hakirya, P.O. Box 7079, Tel Aviv 67441, Israel.
6/1/34750

General examination revealed no special pathologic condition. The abdomen was soft without tenderness or guarding, but there was severe vaginal bleeding, tenderness, and swelling in the sacral area and the vulva. The patient advised that because she had been due to menstruate she had inserted a tampon that was present at the accident. However, she had removed the tampon before arriving at the hospital.

On arrival in the emergency room, an intravenous line was established with lactated Ringer's solution. Hemoglobin count was 12 gm/dl, and hematocrit was 34%. After the vagina was cleared of clots, the source of the bleeding was discovered to be a crescent-shaped laceration high in the left fornix. The patient was immediately transferred to the operating room and given a general anesthetic. A vaginal tear approximately 7 cm long that extended from the left lateral fornix to the posterior fornix was found. There were a few more superficial vaginal lacerations. The tear was sutured with single stitches of 1-0 catgut.

After the repair was completed, hemoglobin count was 9.1 gm/dl, with hematocrit of 27%.

The patient was discharged 2 days later in good condition.

Comment

In the literature there are few reports regarding vaginal tears resulting from waterskiing. Women who are active in water sports such as waterskiing are potentially susceptible to injuries that include sprains, limb fractures, sinusitis, trauma to the tympanic membrane, and injuries to the urethra and urinary bladder.[1] To the best of our knowledge there is no report about vaginal tears after sliding down a water chute.

A review of case reports about vaginal tears that occurred while the patient was waterskiing show that the accident occurs in the first stage of skiing: The skier is still in the water, her legs in front of her, and as she is pulled forward by the accelerating boat, water that is under high pressure hits the perineum.

The normal, unaroused vagina is a potential space that is H-shaped when viewed end-on with the anterior and posterior wall opposed.

Matsala[2] reviewed traumatic injuries to the vagina during sexual intercourse and reported that most of the tears are located in the upper two thirds of the vagina. During intercourse this part of the vagina stretches to 20% to 30% more than its usual length; its inner diameter increases twofold to threefold. The uterus is pulled from its usual location, causing a change in the anatomic relationships within the pelvis and in vaginal symmetry. With our knowledge of sexually related trauma, we can attempt to explain the mechanism by which our patient sustained her injuries.

When a woman slides down a water chute, her uterus is tilted forward because of the acceleration, thus stretching the vaginal wall. If her legs are abducted, the brunt of the water's impact will be to the perineum. Water, under high pressure, enters the vagina, dilates its walls, and causes injury to the upper two thirds of the vagina. Moreover, our patient wore a vaginal tampon, which may have had a pistonlike effect that added to the stretching forces on the vagina.

Treatment includes the control of bleeding, treating hemorrhagic shock if present, repairing the tear, and preventing possible infection by giving the patient antibiotics.

We recommend that women who use water chutes be instructed to slide down with their legs adducted, so that the feet, not the perineum, will be the first to hit the water. Moreover, women should not use tampons while engaged in this activity.

Fetal urine biochemistry in the assessment of obstructive uropathy

K.H. Nicolaides, MD,[a] H.H. Cheng, MD,[a] R.J.M. Snijders, MSc,[a] and C.F. Moniz, MD[b]

London, England

In 60 fetuses with obstructive uropathy, sodium, total calcium, urea, and creatinine were measured in samples obtained by "urodochocentesis" or pyelocentesis at 16 to 36 weeks' gestation. The patients were retrospectively assigned into two groups on the basis of outcome. Group 1 (n = 20) included infants who either had normal postnatal renal function or absence of prenatal renal dysplasia. Group 2 included infants who either had histologic evidence of renal dysplasia or subsequently developed renal failure. In group 1 the urinary sodium decreased and creatinine increased with gestation, demonstrating maturation in fetal renal function. In group 2 the urinary sodium and calcium were higher and the urinary urea and creatinine were lower than in group 1. The best predictor of outcome was the combination of either high calcium or high sodium with a positive predictive value of 91.3% and negative predictive value of 77.7%. In the antenatal evaluation of obstructive uropathy, fetal urinary biochemistry provides useful information for more accurate counseling of the parents and a rational basis for selecting patients who may benefit from intrauterine therapeutic interventions. (Am J Obstet Gynecol 1992;166:932-7.)

Key words: Fetal urine, fetal obstructive uropathy, urodochocentesis, pyelocentesis, ultrasonographic diagnosis

Prenatally, several parameters have been used in the evaluation of renal function in fetuses with obstructive uropathy, including amniotic fluid volume, ultrasonographic appearance of kidneys, and biochemical composition of fetal urine. The latter provides the most accurate information, and poor renal function is inferred from the findings of a high urinary sodium level (>100 mmol/L) and low urinary urea (<6 mmol/L) and creatinine (>150 μmol/L) levels.[1, 2]

In a retrospective study of 40 fetuses with obstructive uropathy Crombleholme et al.[1] reported that a urine sodium level of >100 mmol/L was predictive of poor prognosis, whereas a sodium level of <100 mmol/L was associated with good renal function. Similarly, Grannum et al.[3] measured urinary sodium in 12 fetuses with obstructive uropathy and demonstrated that the four fetuses with levels <100 mmol/L had either normal neonatal renal function or no evidence of renal dysplasia, whereas the eight fetuses with levels >100 mmol/L had renal dysplasia.

In contrast, Wilkins et al.[4] and Elder et al.[5] reported that fetal urine electrolytes are not accurate predictors of outcome. Thus in their combined series of 13 fetuses with obstructive uropathy only four of the seven with urinary sodium levels >100 mmol/L had poor outcome or histologic evidence of renal dysplasia, and only one of the six fetuses with levels <100 mmol/L had good renal function after birth.

One possible explanation for the apparent discrepancy in results is that in these studies no consideration was given for the gestation at which their fetuses were sampled; animal studies have demonstrated that the composition of fetal urine changes with gestation.[6, 7]

The aim of this study was to establish reference ranges with gestation for fetal urine sodium, calcium, urea, and creatinine and to examine the value of these substances in predicting the outcome of 60 fetuses with obstructive uropathy.

Patients and methods

In 60 fetuses with obstructive uropathy, urine samples were obtained by "urodochocentesis" (n = 52) or pyelocentesis (n = 8) at 16 to 36 weeks' gestation and sodium, total calcium, urea, and creatinine levels were measured on a multichannel, continuous-flow analyzer (SMAC II, Technicon, Basingstoke, United Kingdom). Urodochocentesis and pyelocentesis involve the ultrasonographically guided transabdominal insertion of a 20-gauge needle into the fetal bladder or renal pelvis, respectively, and the aspiration of urine. Urodochocentesis was performed when the fetal bladder was dilated and the ultrasonographic appearance of the two kidneys was similar. Pyelocentesis was performed when there was unilateral pelvicaliceal dilatation. In all cases fetal blood sampling and cytogenetic analysis demon-

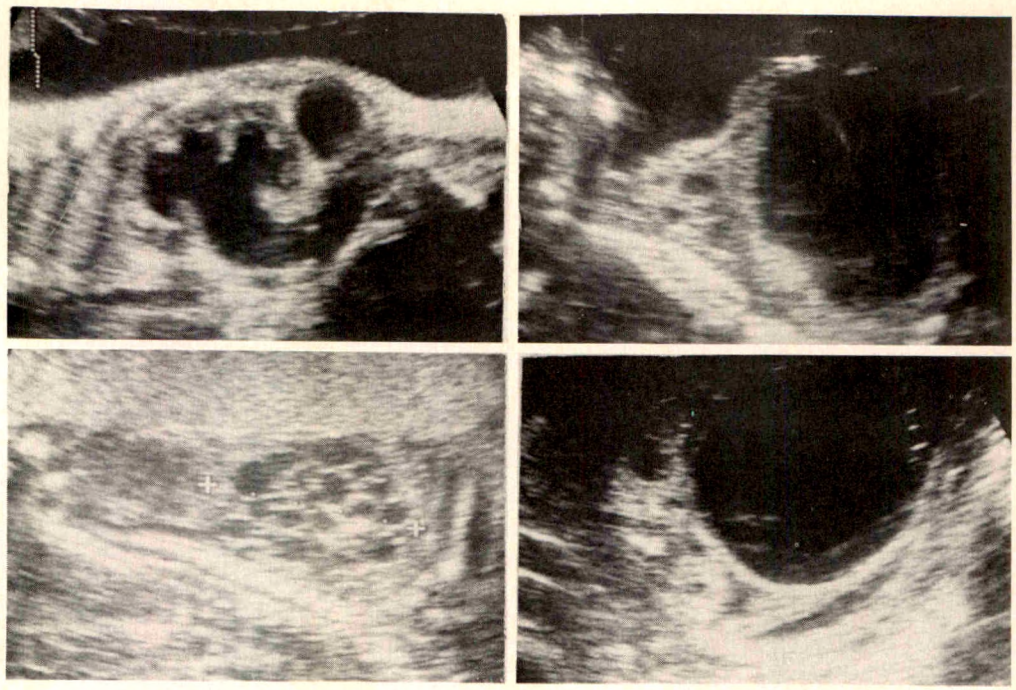

Fig. 1. Ultrasonographic appearance of fetal hydronephrosis with moderate-to-severe pelvicaliceal dilatation *(top left)*, multicystic dysplasia *(bottom left)*, and mild hydronephrosis with hyperechogenic cortex; longitudinal section shows dilated bladder *(top right)* and transverse section shows dilated bladder and echogenic kidneys *(bottom right)*.

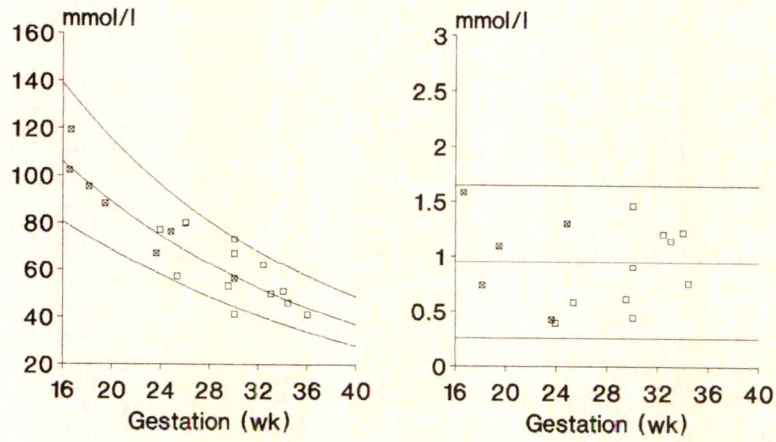

Fig. 2. Reference ranges (mean, 95th and 5th percentiles) with gestation for urinary sodium *(left)* and calcium *(right)* concentrations, calculated from study of fetuses with obstructive uropathy who either survived with normal postnatal renal function (□) or died but had no histologic evidence of renal dysplasia (☒).

strated a normal karyotype. The current study does not include data from fetuses who underwent vesicoamniotic shunting because this may have influenced the natural history of the disease. Similarly, the data from chromosomally abnormal fetuses that were sampled during the same period (1984 through 1990) are excluded.

Ultrasonographically the fetal kidneys were subdivided into three groups: (1) hydronephrotic with moderate-to-severe pelvicaliceal dilatation, $n = 40$; (2) multicystic dysplastic with multiple noncommunicating cysts of variable size and irregular, hyperechogenic stroma, $n = 9$; (3) mildly hydronephrotic with hyperechogenic cortex, $n = 11$ (Fig. 1). The latter type is commonly found in the presence of a grossly dilated bladder, usually before 20 weeks; in those cases where vesicoamniotic shunting is performed, after 4 to 8 weeks these kidneys usually develop the typical irreg-

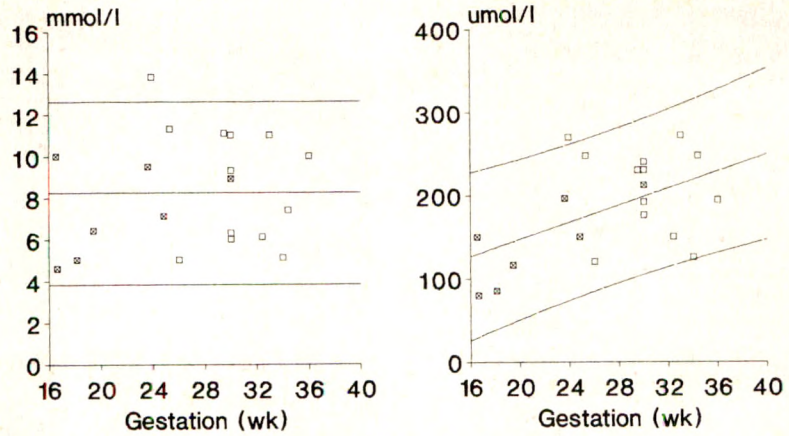

Fig. 3. Reference ranges (mean, 95th and 5th percentiles) with gestation for urinary urea *(left)* and creatinine *(right)* concentrations, calculated from study of fetuses with obstructive uropathy who either survived with normal postnatal renal function (□) or died but had no histologic evidence of renal dysplasia (☒).

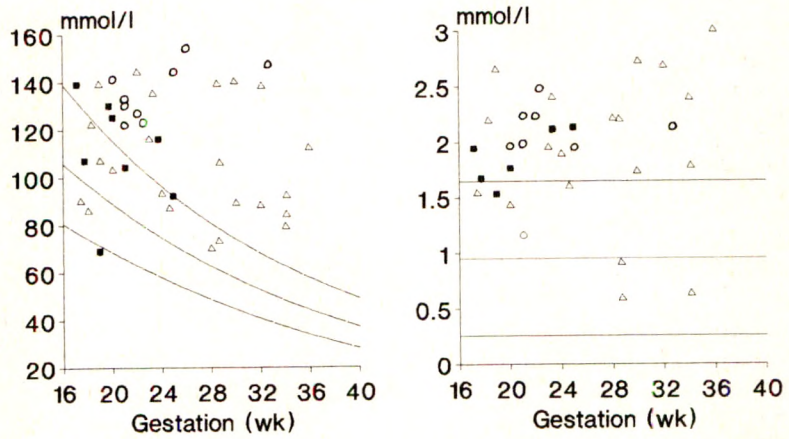

Fig. 4. Urinary sodium *(left)* and calcium *(right)* concentrations in fetuses with obstructive uropathy who either had histologic evidence of renal dysplasia or subsequently showed renal failure plotted on the appropriate reference range (mean, 95th and 5th percentiles) with gestation. Ultrasonographically, fetal kidneys were classified as hydronephrotic with moderate-to-severe pelvicaliceal dilatation (△), multicystic dysplastic (○), or mildly hydronephrotic with hyperechogenic cortex (●).

ular, shrunken, cystic, hyperechogenic appearances found in Potter stage IIb renal dysplasia (unpublished observations).

The 60 patients were retrospectively assigned into two groups on the basis of outcome. In group 1 (n = 20) 13 infants are alive with normal renal function (plasma creatinine concentration <70 μmol/L) at 1 to 6 (mean 2.1) years of age and seven fetuses were electively aborted (n = 6) or died in utero (n = 1) but had no histologic evidence of renal dysplasia. Group 2 (n = 40) includes (1) cases with histologic evidence of renal dysplasia (fetuses that were electively aborted, n = 22; fetuses that died in utero, n = 2; infants who died, n = 7; infants who are alive but required nephrectomy of the kidney sampled in utero, n = 4) and (2) infants who are in chronic renal failure at the age of 1 to 5 (mean 2.6) years (n = 5).

All patients were referred to our unit for diagnosis and further assessment. Subsequent management of the pregnancies was undertaken in the referring hospitals that provided the data on postmortem findings or follow-up of surviving infants.

Results

In group 1 there were significant associations between gestational age and fetal urinary sodium ($\log^{10}$ sodium concentration in millimoles per liter = 2.328 − 0.019 × gestational weeks, residual SD 0.062, r = 0.89, n = 20, $p < 0.0001$) and creatinine (creatinine concentration in micromoles per liter = 45.058 +

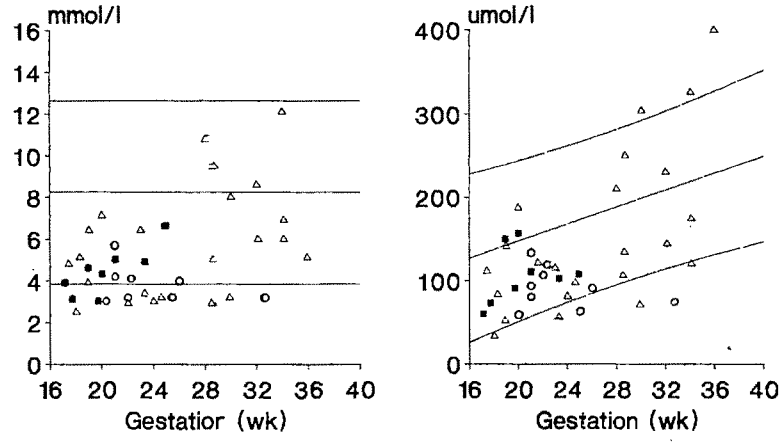

Fig. 5. Urinary urea *(left)* and creatinine *(right)* concentrations in fetuses with obstructive uropathy and either histologic evidence of renal dysplasia or subsequent development of renal failure plotted on appropriate reference ranges (mean, 95th and 5th percentiles) with gestation. Ultrasonographically, fetal kidneys were classified as hydronephrotic with moderate-to-severe pelvicaliceal dilatation (▲), multicystic dysplastic (○), or hydronephrotic with hyperechogenic cortex (●).

Table I. Incidence of oligohydramnios, high (>95th percentile) sodium or calcium levels, and low (<5th percentile) urea or creatinine levels in 60 cases of fetal obstructive uropathy grouped according to good or poor prognosis and subgrouped according to ultrasonographic appearances of fetal kidneys

	Group 1: Good prognosis			*Group 2: Poor prognosis*					
	Total	*Moderate-to-severe hydronephrosis*	*Mild hydronephrosis with hyperechogenic cortex*	*Total*	*Moderate-to-severe hydronephrosis*	*Mild hydronephrosis with hyperechogenic cortex*	*Multicystic dysplasia*	*Positive predictive value*	*Negative predictive value*
Oligohydramnios	5/20	4/17	1/3	25/40	13/23	6/8	8/9	77.8	52.2
Sodium >95th percentile	1/20	1/17	0/3	29/40	15/23	5/8	9/9	94.4	65.2
Calcium >95th percentile	0/17	0/15	0/2	25/33	13/19	5/6	7/8	95.0	71.4
Sodium/calcium >95th percentile	0/20	0/17	0/3	13/40	7/23	2/8	4/9	91.3	77.7
Urea <5th percentile	1/20	1/17	0/3	10/40	6/23	0/8	4/9	83.3	42.8
Creatinine <5th percentile	1/17	1/15	0/2	28/34	15/19	5/7	8/8	100.0	44.4

Positive and negative predictive values were calculated from the 41 cases in which the kidneys showed moderate-to-severe hydronephrosis or mild hydronephrosis with hyperechogenic cortex and all urinary substances were measured; cases of multicystic dysplasia were excluded because ultrasonographic appearances alone were always predictive of poor prognosis.

5.119 × gestational weeks, residual SD 52.453, $r = 0.52$, $n = 20$, $p < 0.05$) but not calcium (mean 0.935 mmol/L, residual SD 0.422) or urea (mean 8.245 mmol/L, residual SD 2.674). Reference ranges for these substances with gestation were established by regression analysis after it was ensured that the data were normally distributed (Figs. 2 and 3).

In group 2 the mean urinary sodium and calcium values were significantly higher ($t = 5.74$, $p < 0.0001$ and $t = 3.4$, $p < 0.01$, respectively) and the mean urinary urea and creatinine values ($t = 4.84$, $p < 0.0001$ and $t = -2.08$, $p < 0.05$, respectively) were significantly lower than in group 1 fetuses (Figs. 4 and 5).

The predictive value of the ultrasonographic appearance of the kidneys, oligohydramnios (no vertical pool of amniotic fluid ≥1 cm), and high (>95th percentile) sodium or calcium levels and low (<5th percentile) urea or creatinine levels are shown in Table I. All cases with multicystic kidneys had a bad outcome (renal dysplasia). However, 3 of the 9 (33%) fetuses with mildly hydronephrotic, hyperechogenic kidneys

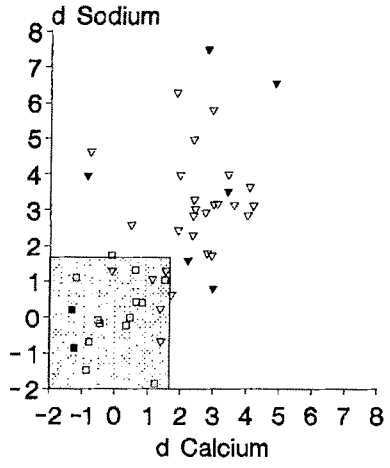

Fig. 6. Urinary sodium and calcium concentrations (expressed as numbers of standard deviations from appropriate normal mean for gestation) in fetuses with obstructive uropathy and either good (□) or poor (◇) prognosis. In 35 of 40 cases from poor prognosis group either sodium or calcium concentration was >95th percentile of reference ranges *(shaded areas)*. Biochemical findings of samples obtained from renal pelvis *(filled symbols)* are similar to those of samples from bladder.

and 17 of the 40 (43%) with moderate-to-severe hydronephrosis had a good outcome (no renal dysplasia or good renal function). In the latter two groups the best predictor (positive and negative predictive value) of outcome was the combination with either high calcium or high sodium (Fig. 6). There was no obvious difference in biochemical results of samples obtained by pyelocentesis and urodochocentesis.

Comment

This study establishes that in fetuses with obstructive uropathy and either normal postnatal renal function or absence of prenatal renal dysplasia the urinary sodium level decreases and the creatinine level increases with gestation, whereas values of calcium and urea do not change. In fetuses with obstructive uropathy and either histologic evidence of renal dysplasia or subsequent development of renal failure the urinary sodium and calcium levels are higher and the urinary urea and creatinine levels are lower than in the good prognosis group.

The concentration of urinary electrolytes and solutes in the good prognosis group, from which the reference ranges were established, is not necessarily representative of urinary biochemical findings in normal fetuses. However, establishment of normal ranges would be impossible. Furthermore, in the prenatal assessment of a fetus with obstructive uropathy it may be preferable to evaluate urinary biochemical levels in relation to reference ranges from fetuses with obstructive uropathy and good outcome rather than from normal fetuses.

Nevertheless, the number of cases used for construction of the reference ranges is small and the end points for inclusion are heterogeneous; lack of histologic evidence for intrauterine renal dysplasia in 7 of the 20 cases does not necessarily imply normal postnatal renal function. Furthermore, plasma creatinine levels of <70 μmol/L at 1 to 6 years does not guarantee that good renal function will persist. Indeed, in children with obstructive uropathy good renal function in the first few years of life is not necessarily predictive of good long-term outcome.[8] Therefore to establish more reliable reference ranges it will be necessary to undertake a multicenter study involving large numbers of fetuses with obstructive uropathy undergoing urodochocentesis, but not vesicoamniotic shunting, and surviving with normal renal function after long-term follow-up.

The urinary biochemical findings in the good prognosis group demonstrate a gestation-related maturation in fetal renal function. In normal urine production there is tubular reabsorption of sodium from an ultrafiltrate of serum. The fetal plasma sodium level is the same as that of the mother and does not change with gestation; therefore the observed decrease in urinary sodium concentration with gestation presumably reflects maturation in tubular reabsorption. Lind et al.[9] obtained fetal urine samples at hysterotomy for elective abortion at 12 to 22 weeks' gestation and demonstrated that as early as 12 weeks the kidney has considerable ability to resorb sodium. The high urinary sodium levels in fetuses with renal dysplasia are indicative of either tubular damage, presumably caused by the obstruction or primary maldevelopment of the kidneys, which is the most likely explanation for multicystic dysplasia.

Although calcium is also resorbed in the tubules, the fetal urinary concentration does not normally decrease with gestation. The most likely explanation for this finding is that increased tubular resorption with gestation is counterbalanced by the rising concentration of ionized calcium in fetal plasma and therefore in glomerular ultrafiltrate.[10, 11] Alternatively, the maximum resorptive capacity for calcium is fully established by 16 weeks' gestation because calcium is essential for fetal growth and development. The fetal hormone responsible for the strong conservation of calcium is probably parathyroid-related peptide, which is expressed in the fetal kidney as early as 12 weeks.[12] The high urinary calcium concentration in fetuses with renal dysplasia is likely a consequence of both impaired tubular resorption and proteinuria with loss of ionized and protein-bound fractions, respectively.

There is no significant renal resorption or secretion of creatinine, and the urinary concentration of this solute is merely a reflection of tubular resorption of water. The gestation-related increase in urinary creatinine concentration is likely a consequence of maturation of renal tubular function. In fetuses with renal dysplasia the urinary creatinine concentration is lower because

tubular resorption of water is impaired. However, a low creatinine level is not as sensitive a predictor of renal dysplasia as increased sodium or calcium levels. A possible explanation for this is that urinary creatinine concentration reflects not only tubular function but also the gestation-related increasing fetal plasma concentration.[13] This is dependent on muscle mass, which is unlikely to be affected by the degree of renal damage.

The urinary urea concentration does not change with gestation and is approximately three times higher than in fetal plasma.[9] This is unlike urinary sodium, which decreases because of active tubular resorption, or urinary creatinine, which increases because of active water resorption. In renal dysplasia electrolyte and water resorption are impaired, resulting in urinary urea concentrations that approach plasma levels.

In the antenatal evaluation of obstructive uropathy,the ultrasonographic finding of multicystic kidneys is associated with renal dysplasia; abnormal urinary biochemical findings merely confirm poor renal function. In contrast, in hydronephrosis both the degree of pelvicaliceal dilatation and the amniotic fluid volume are poor predictors of outcome; urodochocentesis or pyelocentesis with measurement of sodium, calcium, urea, and creatinine provides useful information for more accurate counseling of the parents. Furthermore, fetal urinary biochemical findings provide a rational basis for selecting patients who may benefit from vesicoamniotic shunting or other intrauterine urinary diversion procedures and allows evaluation of the possible effectiveness of such therapeutic interventions.

Characteristics of three vaginal flora patterns assessed by Gram stain among pregnant women

Sharon L. Hillier, PhD,[a] Marijane A. Krohn, PhD,[b] Robert P. Nugent, PhD,[c] and Ronald S. Gibbs, MD,[d] for the Vaginal Infections and Prematurity Study Group

Seattle, Washington, Bethesda, Maryland, and Denver, Colorado

This study was undertaken to define the characteristics and persistence of vaginal flora in 7918 pregnant women at 23 to 26 weeks' gestation. Vaginal smears were categorized as normal (predominant lactobacilli), intermediate (reduced lactobacilli), or positive for bacterial vaginosis. The women with normal flora were least likely to have elevated vaginal pH, amine odor, milky discharge, or colonization by *Gardnerella, Bacteroides,* or genital mycoplasmas. Women with intermediate vaginal flora had intermediate frequencies of these clinical signs and microorganisms. Group B streptococci and yeast were associated with normal or intermediate flora, whereas *Neisseria gonorrhoeae* and *Chlamydia trachomatis* were recovered more frequently from women with intermediate flora or bacterial vaginosis. *Trichomonas vaginalis* was most associated with intermediate flora. At follow-up, 81% of the women with normal flora had remained normal. Of the women with intermediate flora, 32% acquired bacterial vaginosis and 30% shifted to normal flora. Only 12% of the women with bacterial vaginosis had shifted to normal flora. We conclude that there are two primary stable vaginal flora patterns (normal flora or bacterial vaginosis) and a third less distinct transitional flora pattern between these two. (AM J OBSTET GYNECOL 1992;166:938-44.)

Key words: Bacterial vaginosis, vaginal flora

Pregnant women with the disturbed vaginal flora associated with bacterial vaginosis have an increased risk of amnionitis,[1] postpartum endometritis,[2] and preterm delivery,[3, 4] whereas women with *Lactobacillus*-predominant flora have a reduced risk of preterm delivery.[4] Accordingly, a simple, standardized laboratory test for evaluation of vaginal flora would be desirable. Direct microscopic evaluation of vaginal smears provides a rapid and inexpensive means of evaluating vaginal flora. First described by Dunkelberg[5] and later by Spiegel et al.,[6] the sensitivity of vaginal smears for diagnosis of bacterial vaginosis has ranged from 62% to 97% in three recent studies, with specificities of 66% to 95%.[7-9] The sensitivity and specificity of this method have varied, depending on the population studied and the evaluators of the smears. The low sensitivity or specificity for this test may be due to those smears that are neither *Lactobacillus* predominant nor typical of bacterial vaginosis but are forced into one or the other category because of the dichotomous nature of the criteria of Spiegel et al.[6]

Recently the intercenter reliability and reproducibility of recognizing various bacterial morphotypes in vaginal smears were evaluated.[10] The ability to diagnose bacterial vaginosis with the criteria of Spiegel et al. was only moderately reliable because of the wide variability in recognition of bacterial morphotypes by Gram smear evaluators.[10] A standardized scoring system for assessing the vaginal flora by Gram-stained smear was devised on the basis of the most reliably recognized morphotypes: large gram-positive rods (lactobacilli), small gram-negative to gram-variable rods (*Bacteroides* or *Gardnerella*), and curved gram-negative to gram-variable rods (*Mobiluncus*).[10, 11] The advantage of this objective scoring system is that it can accommodate flora patterns that are not typical of either normal flora or bacterial vaginosis.

To describe the association of genital microbiologic features and clinical signs with various vaginal flora patterns, we applied this standardized method in a large cohort of pregnant women. The epidemiologic characteristics associated with different patterns of vaginal flora and the persistence of these vaginal flora patterns during pregnancy are described.

Material and methods

Patient population. Included in this study were 7918 women from five medical centers: Columbia Presbyterian Hospital, New York (2437 women); the University of Texas Health Science Center in San Antonio (1244 women); Louisiana State University, New Orleans (1460 women); the University of Washington, Seattle (611 women); and the University of Oklahoma Health Science Center, Oklahoma City (2166 women). To maximize consistency among the five study centers, all questionnaires, clinical examinations, and microbiologic procedures were performed according to a standardized protocol agreed on by the principal investigators at each center. In addition, one of the authors (R.P.N.) selectively observed the administration of questionnaires and the performance of clinical examinations at each site to optimize standardization. External quality control specimens were evaluated by the laboratories at each center for comparability, and all laboratories used commercially available reagents and media.

All women were enrolled during a routine prenatal visit at 23 and 26 completed weeks of gestation. A standardized medical, obstetric, sexual, and social history and cultures of the vagina and cervix were obtained. Women were excluded from the study for the following reasons: insulin-dependent diabetes mellitis, current use of corticosteroids or digitalis, chronic renal disease (serum creatinine level >2.5 mg/dl), symptomatic organic heart disease, plans to deliver at a nonstudy hospital, multiple gestation, prior use of tocolytic agents during the current pregnancy, cervical cerclage, hypertension requiring medication, age <16 years, Rh isoimmunization, or antibiotic use in the preceding 2 weeks. All women gave written informed consent approved by the respective institutional review boards of the participating centers.

Specimen collection. A clean, unlubricated speculum was placed into the vagina, and the appearance and pH of the vaginal discharge were noted. Sterile cotton swabs were used to obtain vaginal material from the posterior vaginal fornix for a vaginal smear. Prereduced sterile phosphate-buffered saline solution (3 ml) was placed into the vagina, and a vaginal wash suspension was prepared by swabbing discharge from the lateral vaginal walls. The suspension was then removed with a syringe and injected into an oxygen-free tube for transport. Discharge was wiped from the cervical portio, and the appearance of endocervical mucus and the cervix was noted.

Microbiologic methods. An endocervical swab for culture of *Neisseria gonorrhoeae* was used to inoculate Thayer-Martin and chocolate agar plates, which were incubated for 48 hours at 37° C in an atmosphere of 7% carbon dioxide. Cervical Dacron swabs for culture of *Chlamydia trachomatis* were transported in sucrose-phosphate buffer and inoculated onto cycloheximide-treated McCoy cells. *C. trachomatis* was identified within the infected monolayer by staining with fluorescent-labeled monoclonal antibodies.

A vaginal swab was used to inoculate Diamond's media for isolation of *Trichomonas vaginalis*, which was incubated at 37° C for 5 days in 7% carbon dioxide. Trichomonads were identified by visualizing motile forms in the wet mount of the broth under magnification ×400. Vaginal wash suspension (50 μl) was inoculated onto solid mycoplasma media and into broth media for the recovery of *Ureaplasma urealyticum* and *Mycoplasma hominis*. Genital mycoplasmas were identified by typical morphologic characteristics on solid media. Liquid media were examined daily for 7 days, and a color change indicating growth was confirmed by identifying typical colonies on subculture onto solid media.

Fifty microliters of the vaginal wash suspension was used to inoculate a sheep blood agar plate, human bilayer Tween agar, and a chocolate agar plate, which was incubated at 37° C in 5% to 7% carbon dioxide for 24 to 48 hours. Vaginal wash was also used to inoculate a selective broth for recovery of group B streptococci. For recovery of *Bacteroides* species, 50 μl of vaginal wash suspension was used to inoculate either a prereduced *Brucella* or Centers for Disease Control anaerobic blood agar plate and a laked blood kanamycin agar plate, which were incubated in either anaerobe jars (Oxford, Baltimore, or BBL, Cockeysville, Md.) or an anaerobic glovebox (Coy Laboratory Products, Ann Arbor) for 4 to 5 days at 37° C. *Gardnerella vaginalis* was identified by hemolysis on human blood agar, catalase reaction, typical Gram stain morphologic features, and lack of hemolysis on sheep blood agar. Facultative lactobacilli were identified by Gram stain morphologic features, catalase reaction, and colony morphologic features. Group B streptococci were typed with the Streptex latex agglutination typing system (Wellcome Diagnostics, Research Triangle Park, N.C.). Yeasts were identified by standard methods. *Bacteroides* spp. were identified by analysis of fatty acids by gas chromatography, the API A and An-Ident (Analytab products, Plainview, N.Y.), or the Minitek system (BBL Microbiology Systems). *Bacteroides* were identified only when present in high concentrations, i.e., growing in the third or fourth zone of the anaerobic agar plate. Because there was a lack of consistency between study centers with respect to the isolation of anaerobic gram-positive cocci, the data for peptostreptococci have not been included.

Criteria for evaluation of vaginal smears. Vaginal smears were air-dried, Gram stained, and evaluated under magnification ×1000. A score of 0 to 10 was

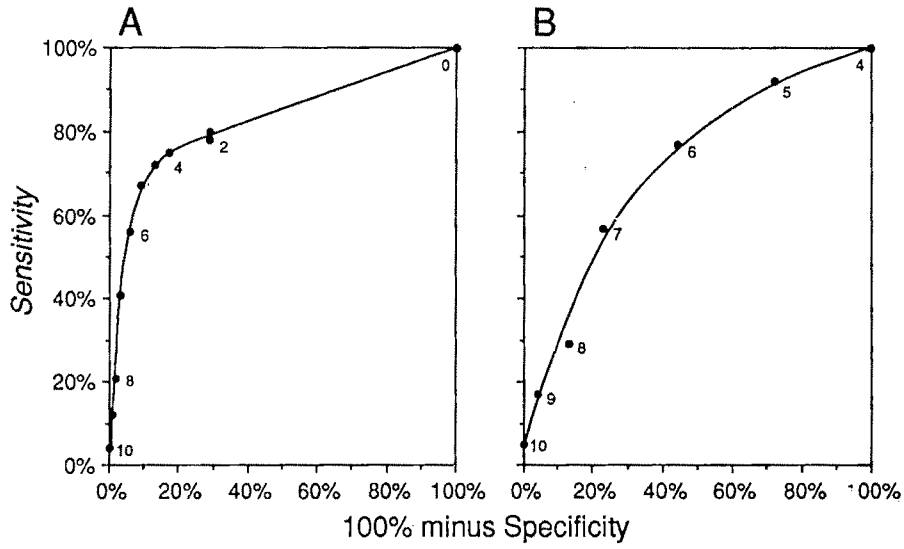

Fig. 1. Receiver-operator characteristic curves for bacterial vaginosis diagnosed by clinical signs and vaginal Gram smear score (0 to 10). Receiver-operator characteristic curves for scores of 0 to 10 **(A)** and 4 to 10 **(B)** suggest that there should be three divisions of the score at 0 to 3, 4 to 6, and 7 to 10.

assigned on the basis of the relative proportion of bacterial morphotypes (large gram-positive rods, small gram-negative or variable rods, or curved rods), with a score of 0 corresponding to the most *Lactobacillus*-predominant vaginal flora and a score of 10 corresponding to a vaginal flora characterized by replacement of lactobacilli by *Gardnerella, Bacteroides,* and *Mobiluncus* morphotypes. The vaginal Gram stain score was determined as follows: 4+ lactobacilli, 0; 3+ lactobacilli, 1; 2+ lactobacilli, 2; 1+ lactobacilli, 3; 0 lactobacilli, 4; 1+ *Gardnerella/Bacteroides,* 1; 2+ *Gardnerella/Bacteroides,* 2; 3+ *Gardnerella/Bacteroides,* 3; 4+ *Gardnerella/Bacteroides,* 4; 1+ to 2+ *Mobiluncus* spp., 1; 3 to 4+ *Mobiluncus* spp., 2.

Receiver-operator characteristic curves were formed by graphing the sensitivity versus 1 − specificity of the 0 to 10 score in predicting bacterial vaginosis diagnosed by three of four clinical signs.[12] The presence of three of four clinical signs (vaginal pH >4.5, amine odor after addition of 10% potassium hydroxide, the presence of clue cells, and a milky discharge) has been commonly used as the standard clinical diagnosis of bacterial vaginosis.[7] Because the wet mount examinations were not performed on all women, the association of the vaginal Gram smear score and the diagnosis of bacterial vaginosis with the standard clinical criteria was assessed in the subset of 711 women having clue cell examinations. To establish subcategories of the vaginal smear score, the association of the 0 to 10 score with the clinical signs of bacterial vaginosis was described by a receiver-operator characteristic curve.[12] The receiver-opertor characteristic curve discriminated between the frequency of bacterial vaginosis diagnosed by clinical signs among women who had a score from 0 to 3 (87% specificity) and women who had a score from 4 to 10 (72% sensitivity) (Fig. 1, *A*). A second receiver-operator characteristic curve was used to test the relationship of a score from 4 to 10 with the clinical signs of bacterial vaginosis (Fig. 1, *B*). Women with a score of 7 to 10 had a higher frequency of the clinical signs associated with bacterial vaginosis (78%) than women with a score of 4 to 6 (45%). These findings suggested three subdivisions of the 0 to 10 Gram stain score: normal, 0 to 3; intermediate, 4 to 6; and bacterial vaginosis, 7 to 10.

Analysis. Data were entered onto paper forms and mailed to the Data Coordinating Center (Research Triangle Institute, Research Triangle Park, N.C.) where the forms were entered into a mainframe computer. Data forms were edited and returned to the clinical centers for corrections where indicated. Data analysis was done with the Statistical Analysis System (SAS is the registered trademark of SAS Institute, Inc., Cary, N.C.).

χ^2 Tests were used to determine the statistical significance of the frequencies of genital isolates among the vaginal flora patterns.[13] The association of demographic characteristics with vaginal flora patterns were expressed by risk ratios and were assessed for statistical significance by 95% confidence intervals.[13] The adjustment of one demographic characteristic for another was performed by Mantel-Haenszel stratified analysis.[14]

Results

Of the 7918 women enrolled, 61% had vaginal smears consistent with normal flora, 16% intermediate flora, and 22% bacterial vaginosis. The proportion of women having elevated vaginal pH, amine odor, and milky discharge is shown in Fig. 2. The presence of a

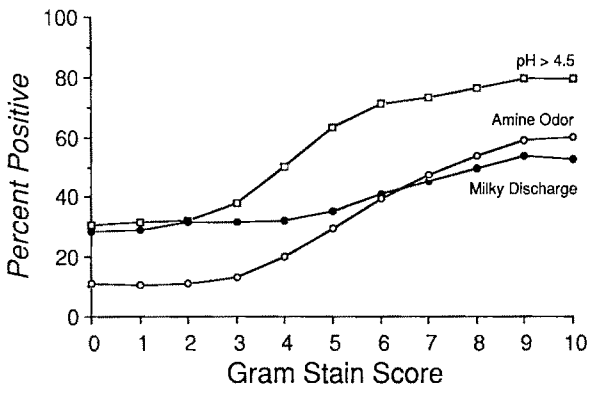

Fig. 2. Percent of women with positive results for milky vaginal discharge (●), amine odor after addition of 10% potassium hydroxide (○), and vaginal pH >4.5 (□).

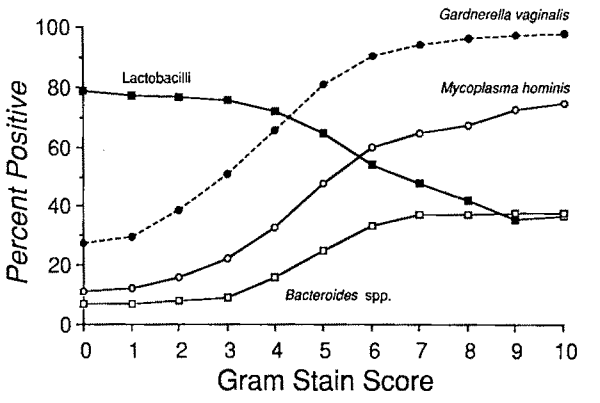

Fig. 3. Percent of women with positive results for facultative lactobacilli (■), *G. vaginalis* (●), *M. hominis* (○), and *Bacteroides* species (□).

Table I. Recovery of microorganisms from pregnant women with various vaginal flora patterns

	Gram smear interpretation		
	Normal	*Intermediate*	*Bacterial vaginosis*
G. vaginalis	1533/4867 (31%)	1040/1292 (80%)*	1692/1759 (96%)*

*$p < 0.001$, compared with women with normal vaginal flora.
†Identified only when present in third or fourth streak zone of the agar plate.

milky discharge, a vaginal pH >4.5, and the release of amine odor after addition of 10% potassium hydroxide to the vaginal fluid was associated with an increasing vaginal Gram stain score. The data were similar at all five study centers.

The vaginal and cervical microbiologic characteristics stratified by vaginal flora patterns are presented in Table I. Since the vaginal score is based on a composite of *Lactobacillus, Gardnerella, Bacteroides,* and *Mobiluncus* morphotypes, it is not surprising that a strong association between these organisms and the vaginal flora patterns was observed (Fig. 3). The low frequency of *Bacteroides* species was not unexpected because only those isolates present at high concentrations (3+ to 4+) were reported. The degree of concordance between the smear interpretation and vaginal isolation suggests that these morphotypes can be recognized by direct examination of vaginal smears. *M. hominis,* an organism that cannot be observed in Gram-stained smears, was also recovered more frequently among women with intermediate flora or bacterial vaginosis (Fig. 3).

Group B streptococci were recovered from the vagina in 18% of the women. The recovery of group B streptococci was associated with a normal and intermediate vaginal flora (Table I). *U. urealyticum* was recovered less often from women with normal flora than from women with intermediate flora or bacterial vaginosis.

Women with normal vaginal flora were significantly less likely to be infected by *N. gonorrhoeae, C. trachomatis,* or *T. vaginalis* (Table I), suggesting an increased frequency of sexually transmitted disease pathogens in women with decreased lactobacilli (Fig. 4). The frequency of *N. gonorrhoeae* and *C. trachomatis* was similar for women with an intermediate or bacterial vaginosis flora pattern. However, *T. vaginalis* was most frequently recovered from women with intermediate vaginal flora (Fig. 4). *Candida* species were recovered from similar frequencies of women with normal and intermediate flora but were recovered significantly less frequently from women with bacterial vaginosis (Table I).

When compared with normal women, women with bacterial vaginosis were significantly more likely to be unmarried (relative risk 1.5, 95% confidence interval 1.4 to 1.7) and black (relative risk 1.7, 95% confidence interval 1.6 to 1.8) and less likely to have used an an-

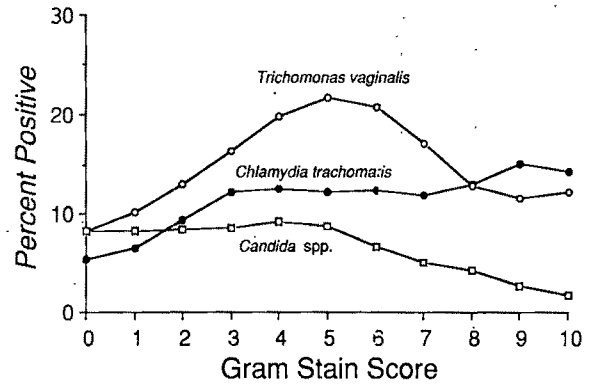

Fig. 4. Percent of women with positive results for *C. trachomatis* (●), *T. vaginalis* (○), and *Candida* species (□).

tibiotic before enrollment (relative risk 0.8, 95% confidence interval 0.7 to 0.9). The relationship between being black and having bacterial vaginosis was seen in four of the study centers. In New Orleans >85% of the women enrolled were black, so it was not possible to assess this relationship. The relationship between having bacterial vaginosis and being unmarried was statistically significant after adjustment for being black (risk ratio 1.3, 95% confidence interval 1.2 to 1.4). Bacterial vaginosis was not significantly related to a younger age at first intercourse, having had more than one sexual partner during the current pregnancy, more lifetime sexual partners, frequency of intercourse, smoking, drinking, gravidity, or parity (data not shown).

Women having an intermediate vaginal flora pattern were more likely than women with normal flora to be teenagers (relative risk 1.3, 95% confidence interval 1.2 to 1.5), to be black (relative risk 1.6, 95% confidence interval 1.4 to 1.7), to have had more than one sexual partner during the current pregnancy (relative risk 1.4, 95% confidence interval 1.1 to 1.6), and to have used antibiotics during the current pregnancy (relative risk 1.3, 95% confidence interval 1.2 to 1.4). The association between an intermediate vaginal flora pattern and these factors was consistent among all the study centers and was not altered if women with *T. vaginalis* or other sexually transmitted disease organisms were excluded from the analysis. Marital status, smoking, drinking, frequency of intercourse, gravidity, and parity were not associated with an intermediate flora pattern (data not shown).

Seven hundred sixty-two of the women were reevaluated at a return visit at 31 to 36 weeks' gestation. None of these women had used an antibiotic in the interim. Of the women with normal flora at enrollment, 81% were normal at follow-up (Table II). Of those having an intermediate flora pattern at enrollment, one third had acquired normal flora, one third had acquired bacterial vaginosis, and one third had persistent intermediate flora. Women with bacterial vaginosis flora at enrollment were most likely to have bacterial vaginosis at follow-up (69%), 19% had shifted to intermediate flora, and only 12% of the women shifted to a normal flora pattern.

Comment

The primary finding of the current study is that there are two major vaginal flora patterns and a third transitional vaginal flora, each having differing microbiologic and clinical characteristics. The concept that there are three vaginal flora patterns was first presented by Schroder[15] in 1921. He proposed that vaginal flora corresponded to the *reinheitsgrad* (degree of cleanliness) of the vagina. The first flora group (grade 1) was dominated by lactobacilli and considered to be the least pathogenic. The second group (grade 2) was characterized by mixed bacterial flora and a decrease in lactobacilli, whereas the third, and most pathogenic, group was composed of mixed flora without lactobacilli.[15] Siegler,[16] in 1946, reported that vaginal yeast and *T. vaginalis* were associated with grade 2 flora, whereas gonorrhea was associated with grade 3 flora. In the current study, with the use of standardized criteria for evaluation of the smears, vaginal *Candida* species were associated with normal and intermediate flora, and *C. trachomatis* and *N. gonorrhoeae* infection were more common in women with intermediate flora or bacterial vaginosis. *T. vaginalis,* which may be difficult to distinguish from bacterial vaginosis by clinical criteria, is most strongly associated with intermediate flora. The intermediate and bacterial vaginosis patterns are both associated with a decreased concentration and frequency of lactobacilli. It is not known whether these pathogens inhibit vaginal lactobacilli and thereby cause a shift in the vaginal flora, whether disturbed vaginal flora is a risk factor for acquisition of sexually transmitted disease, or whether there is an undescribed risk factor for both loss of lactobacilli and acquisition of sexually transmitted pathogens. Longitudinal studies will be required to address these issues.

The vaginal Gram stain score allows for a standardized interpretation on the basis of recognition of bacterial morphotypes. In the current study 7918 vaginal smears were interpreted at five centers by 14 different microbiologists. The ability to recognize selected bacterial morphotypes in the vaginal smears is supported by the culture data showing an increased frequency of *Gardnerella* and *Bacteroides* and a decreased frequency of facultative lactobacilli with an increased Gram stain score. *Mobiluncus* species, which are part of the score, were not routinely recovered from anaerobic vaginal cultures because only the anaerobes recovered in the

Table II. Persistence of vaginal flora patterns from enrollment to the third trimesters of pregnancy

Vaginal smear at enrollment (23-26 wk)	*Vaginal gram smear at follow-up (31-36 weeks' gestation)*			
	Total No.	*Normal*	*Intermediate*	*Bacterial vaginosis*
Normal	502	404 (81%)	61 (12%)	37 (7%)
Intermediate	119	36 (30%)	45 (38%)	38 (32%)
Bacterial vaginosis	141	17 (12%)	27 (19%)	97 (69%)

third and fourth streak zones of the culture plates were identified. The recovery of *M. hominis* was also associated with an increasing vaginal Gram stain score. The association of *M. hominis* with a diagnosis of bacterial vaginosis has been reported previously.[4, 9]

A vaginal flora pattern consistent with bacterial vaginosis was associated with being unmarried and black but not with having more lifetime sexual partners or more partners during this pregnancy, more episodes of sexual intercourse, smoking, drinking, or other medical or behavioral characteristics. The lack of association between lifetime sexual partners and bacterial vaginosis has been noted in another study.[17] However, an association between acquisition of bacterial vaginosis and exposure to a new sexual partner in the preceding month was detected in a longitudinal study.[18] It is possible that the cross-sectional nature of the study of Amsel et al.[17] and the current study would fail to detect a temporal relationship between a new sexual partner and acquisition of bacterial vaginosis.

Women with intermediate flora were more likely than women with normal flora to be teenagers, to be black, and to have had more than one sexual partner during pregnancy, even when women with sexually transmitted disease pathogens were excluded. Thus the epidemiologic characteristics associated with intermediate flora were not due to concomitant infection by sexually transmitted disease pathogens. These data suggest that the intermediate vaginal flora pattern may be a marker of increased sexual activity.

There are two stable types of vaginal flora, and a third, less distinct transitional phase between normal and bacterial vaginosis flora. The normal flora pattern appears to be the most stable, persisting in 81% of the women. Intermediate vaginal flora was the least stable, since 62% of the women had either switched to normal flora or acquired bacterial vaginosis between the two visits. Antibiotic use was significantly associated with having intermediate flora at enrollment, suggesting that some women have intermediate flora because of incomplete treatment of bacterial vaginosis or because of killing of lactobacilli by antibiotic therapy.

In the current study 69% of women with bacterial vaginosis in the second trimester of pregnancy also had bacterial vaginosis in the third trimester of pregnancy. Only 12% of the women had established normal flora. Bump et al.[19] have reported that 9 of 14 women had resolution of asymptomatic bacterial vaginosis without treatment in 6 months. Although our period of follow-up was shorter, our data suggest that bacterial vaginosis most often persists during pregnancy or shifts to intermediate rather than normal flora.

Infection by *N. gonorrhoeae,*[20] *C. trachomatis,*[3, 4, 21] and *T. vaginalis*[22] has been associated with adverse pregnancy outcomes. Bacterial vaginosis has been associated with amnionitis,[1, 2] preterm labor,[3, 4] preterm premature rupture of membranes,[4] and postpartum endometritis.[2] Microorganisms associated with bacterial vaginosis, including *M. hominis,*[21] *Bacteroides,*[23-25] and *G. vaginalis,*[25] have been associated with low birth weight or prematurity. Given the overlap between the vaginal flora patterns, these organisms, and infection by sexually transmitted pathogens, it will be of importance to evaluate whether bacterial vaginosis is asociated with prematurity or postpartum endometritis independent of these infections.

The Vaginal Infections and Prematurity Study Group consists of the following: Sumner J. Yaffe, MD, Charlotte Catz, MD, Robert P. Nugent, PhD, George G. Rhoads, MD, MPH (now at the University of Medicine and Dentistry of New Jersey), Donald McNellis, MD, Mark A. Klebanoff, MD, MPH, George F. Reed, PhD, Howard J. Hoffman, MA, and Heinz W. Berendes, MD, MHS, from the National Institute of Child Health and Human Development, Bethesda, Maryland; Robert Edelman, MD (now at the University of Maryland), William C. Blackwelder, PhD, Richard A. Kaslow, MD, MPH, and Mary Frances Cotch, PhD, from the National Institute of Allergy and Infectious Diseases, Bethesda, Maryland; Joan Regan, MD, and Ellen Greenberg, MS, from Columbia University, New York, New York; Sterling Williams, MD, from the Harlem Hospital Center, New York, New York; David H. Martin, MD, Joseph Pastorek, MD, and Cathy Cammarata, from the Louisiana State University, New Orleans, Louisiana; Paul Sommers, MD, from Tulane University, New Orleans, Louisiana; J. Christopher Carey, MD, Philip J. Rettig, MD, and Ron Wilkerson, BA, from the University of Oklahoma, Oklahoma City, Oklahoma; Ronald S. Gibbs, MD (now at the University of Colorado), and Patricia St. Clair, from the University

of Texas, San Antonio, Texas; David Eschenbach, MD, and Sharon Hillier, PhD, from the University of Washington, Seattle, Washington; and A. Vijaya Rao, PhD, and W. Kenneth Poole, PhD, from the Research Triangle Institute, Research Triangle Park, North Carolina.

Preterm premature rupture of membranes: Results of expectant management in patients with cervical cultures positive for group B streptococcus or *Neisseria gonorrhoeae*

George Larry Maxwell, MD, and William J. Watson, MD
Chapel Hill, North Carolina

OBJECTIVE: The antepartum course and short-term neonatal outcome for patients with premature rupture of membranes between 26 and 33 weeks' gestation with positive cervical cultures for group B streptococcus or *Neisseria gonorrhoeae* were reviewed.
STUDY DESIGN: A retrospective analysis of 182 patients managed expectantly over a 3-year period was done. Thirty-four patients had cervical cultures positive for group B streptococcus, 11 had positive cultures for *Neisseria gonorrhoeae*, and 137 had negative cultures. Prophylactic antibiotics were routinely given, and antibiotic therapy was continued in patients with positive cultures.
RESULTS: There was no difference between groups in latent phase or maternal morbidity. The incidence of neonatal pneumonia was increased in those with positive cervical cultures (p = 0.009, odds ratio 6.9, 90% confidence interval 2.1 to 22.8), but there was no difference in neonatal sepsis, respiratory distress, or neonatal mortality.
CONCLUSION: These data support the conservative or expectant management of premature rupture of membranes between 26 and 33 weeks in patients with positive cervical cultures who are given prophylactic antibiotic therapy. (Am J Obstet Gynecol 1992;166:945-9.)

Key words: Premature rupture of membranes, group B streptococcus, *Neisseria gonorrhoeae*

Preterm premature rupture of membranes occurs in approximately 1% of all pregnancies.[1] Most women with this condition will eventually be delivered preterm, and the majority will do so within 7 days, irrespective of gestational age.[2] Infection with certain strains of bacteria may be an important cause;[3-5] an increased incidence of preterm premature rupture of membranes has been found among patients cervically colonized with group B streptococcus[6-8] or *Neisseria gonorrhoeae*.[9]

Although infection is implicated as a neonatal risk in patients with preterm premature rupture of membranes, the complications of prematurity, such as respiratory distress syndrome, are by far the more common causes of perinatal mortality.[10] Recent investigators have failed to show any significant association between preterm premature rupture of membranes[11-13] or a prolonged latent period[14, 15] and subsequent infection; the increased risk of neonatal infection has been primarily attributed to preterm delivery.[12] Expectant (conservative) management has been subsequently advocated to avoid the complications associated with preterm delivery.[11, 12, 14-18]

In this case-control study we sought to determine whether expectant management is justified in a subset of patients with preterm premature rupture of membranes who are at increased risk of maternal and fetal infection: those with positive cervical cultures for group B streptococcus or *Neisseria gonorrhoeae* at the time of membrane rupture. Of particular interest to the practicing obstetrician is the length of the latent period and the incidence of neonatal morbidity and mortality in those patients with positive cervical cultures and expectant management.

Material and methods

The maternal and fetal records were reviewed of all patients with preterm premature rupture of membranes occurring between 26 and 33 weeks' gestation who were admitted to the North Carolina Memorial Hospital obstetric service from July 1987 to September 1990. During this time there were 299 infants born to 275 women with this pregnancy complication. Pregnancies with preterm premature rupture of membranes at ≥34 weeks were not considered, because conservative management at this gestational age is not routinely practiced. Only those with singleton pregnancies in whom conservative management was planned were included in the analysis. Patients with premature rup-

Table I. Comparison of demographics and maternal treatment characteristics in three study groups*

Parameter	Maternal cervical culture			Significance
	Positive group B streptococcus	*Positive gonorrhea*	*Negative*	
No.	34	11	137	
Maternal age (yr, mean ± SD)	25.6 ± 5.6	21.5 ± 4.1	25.1 ± 5.7	$p < 0.05$
Gestational age (wk, mean ± SD)	30.9 ± 2.0	29.8 ± 2.3	30.5 ± 2.2	NS
Parity	1.18	1.27	0.86	NS
Race				
White	12 (35%)	3 (27%)	63 (46%)	
Black	19 (56%)	7 (64%)	59 (43%)	
Other	3 (9%)	1 (9%)	15 (11%)	
Antibiotic use	32 (94%)	11 (100%)	114 (83%)	$p = 0.10$
Steroid use	14 (41%)	5 (45%)	46 (33%)	NS

NS, Not significant ($p > 0.10$). Borderline p values are given.

*The only difference noted was the younger age of those patients with premature rupture of membranes and cervical cultures positive for gonorrhea.

ture of membranes and labor, any sign of amnionitis on presentation, and those with other obstetric complications were not managed expectantly. Because we wanted to assess the effect of positive streptococcus and gonorrhea cultures on maternal and fetal outcome, patients with positive cultures for herpes simplex virus or chlamydia were excluded. Chlamydia cultures were not routinely done in patients with preterm premature rupture of membranes. Ninety-three women were excluded: labor on admission ($n = 41$), chorioamnionitis or fetal distress on admission ($n = 13$), multiple gestation ($n = 20$), herpes simplex virus genital tract colonization ($n = 3$), chlamydia cervical colonization ($n = 6$), known severe fetal anomaly ($n = 1$), placenta previa or severe preeclampsia necessitating delivery ($n = 4$), and records with insufficient documentation ($n = 5$). After these exclusions were made, 182 mother-infant pairs were included in the case-control analysis.

The diagnosis of rupture of membranes was made by history and by positive microscopic ferning and pH testing performed during speculum examination. Digital examinations generally were deferred until the onset of labor. Gestational age was determined by prenatal records, menstrual history, and ultrasonographic measurements made at admission.

At our hospital all patients with preterm premature rupture of membranes are admitted, cervical cultures for group B streptococcus and *N. gonorrhoeae* are routinely done, swab specimens are transported to the microbiology laboratory within 2 hours with Amies Charcoal Transport Medium. The microbiology laboratory bases the protocol for identification of these organisms on recommendations made by the American Society for Microbiology.[19, 20]

Prophylactic antibiotics (usually 1 gm intravenous ampicillin every 4 to 6 hours) were administered immediately and until the results of cervical cultures were known. If the culture for these two organisms was negative at 72 hours, antibiotic therapy was discontinued; in those with positive cultures, oral antibiotic therapy was continued for at least 7 to 10 days.

Steroids, to enhance fetal pulmonary maturity, were administered at the time of admission, at the discretion of each attending perinatologist. This was given as betamethasone, 12.5 mg intramuscularly, two doses, 24 hours apart. Sixty-five of the 182 patients received steriod therapy (Table I).

Expectant management of preterm premature rupture of membranes was practiced, and patients were closely monitored for signs or symptoms of chorioamnionitis. Monitoring consisted of frequent assessment of maternal temperature and uterine tenderness, daily electronic fetal monitoring, and daily or every-other-day determination of maternal white blood cell counts. Amniocentesis was not performed routinely, only if equivocal signs of amnionitis were present. Delivery was accomplished in all patients in whom the clinical diagnosis of chorioamnionitis was made. Tocolytics were not used in the 182 patients with premature rupture of membranes in this analysis.

Maternal outcome was assessed for the length of the latent period, defined as the interval between membrane rupture and active labor. Also assessed were the reason for delivery, the mode of delivery, and the incidence of postpartum endometritis. Neonates were evaluated for birth weight, Apgar scores, respiratory distress syndrome, sepsis confirmed by cultures, sepsis suspected but not proved, pneumonia, intraventricular hemorrhage, and length of neonatal intensive care stay.

Table II. Results of conservative management of preterm premature rupture of membranes: maternal outcome

Parameter	Cervical culture			Significance
	Positive group B streptococcus	*Positive gonorrhea*	*Negative*	
No.	34	11	137	
Latent period				
Mean ± SD (days)	4.7 ± 4.9	7.9 ± 7.9	4.3 ± 5.3	
Median (days)	3.0	2.8	2.6	NS
Range (days)	0.4-17.9	0.5-25.2	0.2-38	
Reason for delivery				$p = 0.06$
Amnionitis	9 (26%)	4 (36%)	30 (22%)	
Active labor	15 (44%)	4 (36%)	90 (66%)	
Fetal distress	6 (18%)	2 (18%)	14 (10%)	
Other	4 (12%)	1 (9%)	3 (2%)	
Cesarean section	6 (18%)	2 (18%)	26 (19%)	NS
Postpartum endometritis	6 (18%)	2 (18%)	29 (21%)	NS

NS, Not significant.

Respiratory distress was a clinical diagnosis, defined as tachypnea, with grunting, retraction, flaring, low oxygen saturation on room air, chest films showing reticulogranular, ground glass–appearing lungs with air bronchograms, and a negative evaluation for sepsis. Suspected sepsis was defined as signs or symptoms of sepsis in an infant with negative cultures, in whom antibiotic therapy was given for ≥3 days.

Statistical comparisons were made with the χ^2 test for discontinuous data and analysis of variance for group means. If data were not normally distributed, the Wilcoxon rank-sum test was used. Linear regression was used to determine the latent period as a function of gestational age. A p value of ≤0.05 was considered significant.

Results

Of 182 women with preterm premature rupture of membranes managed conservatively, the cervical culture obtained at admission was positive for group B streptococcus in 34 (19%) and for *N. gonorrhoeae* in 11 (6%); the cervical culture was negative in 137 (75%). These three groups of patients were compared demographically, as well as for gestational age, and for the use of steroid and prophylactic antibiotic therapy (Table I). The age of those patients with preterm premature rupture of membranes and positive cervical cultures for gonorrhea was significantly lower ($p < 0.05$) than the age of the other two groups. No other significant differences were found. It is important to note that there were no significant differences between the groups in the use of prophylactic antibiotic or steroid therapy.

The outcome of pregnancy, including the length of the latency period, reason for delivery, and cesarean delivery rate, was also compared in these groups, as shown in Table II. It is noteworthy that the latent period was not significantly affected by the presence of cervical colonization with these bacteria. There was no relationship between the length of the latent period and gestational age at premature rupture of membranes ($r = -0.17$, $p = 0.66$). Approximately 60% of the patients went into active labor after a variable period of expectant management. Amnionitis or fetal distress led to delivery in 65 women (36%). The reasons for delivery and the mode of delivery did not differ among the three groups. There was no difference in the incidence of postpartum fever between the three studied groups.

Table III summarizes the neonatal outcome in the three groups. There was no difference in mean birth weight or median time of stay in the intensive care nursery. Similarly, there was no difference in the incidence of proved or suspected sepsis or neonatal death.

There was a significantly increased incidence of pneumonia among the infants of patients with positive cervical cultures (relative risk = 6.9, 90% confidence interval 2.1 to 22.8, $p = 0.009$). Only 5 of the 34 patients with positive streptococcus cultures were classified as having a heavy growth. The median latent period in these 5 infants was 4.2 days, and there were no neonatal deaths. Of the five infants born to mothers with heavy colonization, one had proved sepsis (from *Escherichia coli*) and pneumonia, and one had suspected sepsis.

In patients who received steroid therapy, there was a trend toward a reduction in neonatal respiratory distress syndrome ($p = 0.06$). The use of steroids was not associated with an increased incidence of proved or suspected neonatal sepsis, even in those patients with positive cervical cultures ($p = 0.35$). The small number of patients with positive cultures, however, precludes

Table III. Results of conservative management of preterm premature rupture of membranes: Fetal outcome

NS, Not significant. Infants born to mothers with positive cervical cultures were significantly more likely to have pneumonia. See Comment section for power analysis.

definitive conclusions about the effect of steroids on the incidence of neonatal sepsis.

Comment

The expectant management of patients with preterm premature rupture of membranes and group B streptococcus cervical colonization has been evaluated in one previous study by Newton and Clark.[7] These investigators studied 140 consecutive patients with preterm premature rupture of membranes, 16 of whom were colonized with streptococcus. Patients with positive cultures had earlier rupture of membranes and shorter latent periods (76.8 vs 138.5 hours) than did those with negative cultures.

Amnionitis and endometritis were more common in mothers colonized with streptococcus. Neonatal infections were also significantly elevated in the infants of these mothers. One important difference between the study of Newton and Clark[7] and the current study is the use of prophylactic antibiotic therapy; in the former study antibiotics were only given intrapartum to group B streptococcus carriers. It is most likely that our results differed from theirs because of differences in the use of prophylactic antibiotic therapy.

Our study excluded those patients with situations necessitating aggressive obstetric management (chorioamnionitis, active labor, etc.) before determination of any effects of cervical colonization per se on the length of latent phase. Of those excluded patients, 16 women had positive cultures for streptococcus. The inclusion of these patients may have lead to a shorter latent period being associated with colonization. The practical question that this study addresses is how to care for an asymptomatic patient with preterm premature rupture of membranes managed expectantly, when the cervical culture is positive. In this regard we believe that our study exclusions are justified.

This investigation has two shortcomings. First, the study is retrospective, and relies on identification of abnormalities by different practitioners over a 3-year period. Most, but not all, patients received prophylactic antibiotic therapy (Table I). Although we presently perform chlamydia cultures on all patients with preterm premature rupture of membranes, these were not routinely done during the entire time of this analysis, and this may have confounded our results. However, Newton and Clark[7] did control for the presence of chlamydia and mycoplasmas, and the presence or absence of these organisms did not affect their findings.

Second, our study involves the evaluation of a relatively small population of patients with preterm premature rupture of membranes and positive cervical cultures, which may lead to type II statistical errors, especially when conditions with a low incidence are being studied. An analysis of type II error on neonatal outcome parameters in Table III shows that for neonatal respiratory distress syndrome, the power was >80% to detect a 30% increase in incidence in the patients with positive cervical cultures. Conversely, we would have had to study at least 435 patients to exclude a twofold increase in sepsis and at least 550 patients to exclude a twofold increase in neonatal deaths in the group with positive cultures. Although fetal distress appeared to occur more commonly in those patients with positive

cervical cultures, the factor necessitating delivery was not significantly different between the groups. Again, the finding of no difference may reflect a type II statistical error, because of the small numbers studied.

Nevertheless, the current study does provide a larger patient population on which to base clinical management in patients with this pregnancy complication. In any patient with preterm premature rupture of membranes, the clinician must weigh the risk of prematurity with that of maternal and neonatal infection. The risk of fetal infection appears to be increased by the presence of these bacteria in the maternal genital tract. It remains to be demonstrated, however, whether immediate induction of labor would reduce this risk when positive culture results are found. Particularly in the fetus of earlier gestational age, the risks of prematurity are substantial, and expectant management of selected asymptomatic patients with preterm premature rupture of membranes and a positive cervical culture may be justified to decrease these risks.

Comparison of transdermal and oral estrogen-progestin replacement therapy: Effects on serum lipids and lipoproteins

David Crook, PhD,[a] Michael P. Cust, MB,[a, b] Kevin F. Gangar, MB,[a, b] Melek Worthington, MSc,[a] Timothy C. Hillard, BM,[a, b] John C. Stevenson, MB,[a] Malcolm I. Whitehead, MB,[b] and Victor Wynn, MD[a]

London, England

OBJECTIVE: We attempted to ascertain whether transdermal postmenopausal estrogen-progestin therapy has the typical effects of oral therapy on serum lipoprotein risk markers for cardiovascular disease.

STUDY DESIGN: Sixty-one postmenopausal women were randomized to receive either transdermal continuous 17β-estradiol, 0.05 mg/day, with transdermal cyclic norethindrone acetate, 0.25 mg/day, or oral continuous conjugated equine estrogens, 0.625 mg/day, with oral cyclic *dl*-norgestrel, 0.15 mg/day. Twenty-nine untreated subjects served as controls. Lipoprotein profiles at 3 and 6 months were compared with baseline values by means of analysis of variance.

RESULTS: In the estrogen-alone phase both therapies reduced serum levels of total and low-density lipoprotein cholesterol; high-density lipoproteins were largely unchanged. Oral therapy increased triglycerides whereas this lipid fell with transdermal therapy. In the combined phase of the cycle both therapies reduced triglycerides, total cholesterol, low-density lipoprotein cholesterol, and high-density lipoprotein cholesterol.

CONCLUSION: Transdermal and oral therapies had similar effects on lipoprotein cholesterol but different effects on triglycerides. (Am J Obstet Gynecol 1992;166:950-5.)

Key words: Estrogen, progestin, lipoproteins, cholesterol, triglycerides

In addition to preventing osteoporosis, postmenopausal estrogen replacement therapy reduces the incidence of coronary heart disease, the major long-term consequence of the menopause, by 50%.[1] Although other mechanisms may be operating, this protection is consistent with the ability of oral estrogens to reduce serum levels of low-density lipoprotein (LDL) and raise those of high-density lipoprotein (HDL).[2]

To prevent endometrial hyperplasia and carcinoma, administration of progestin is advisable when treating nonhysterectomized postmenopausal women with estrogen.[5] Because progestins can oppose the potentially protective effects of estrogen on LDL and HDL,[4] there is a need for an effective postmenopausal regimen that retains the favorable lipoprotein profile typical of unopposed estrogen users. Administration of progestin by nonoral routes may achieve this by minimizing the unphysiologically high hepatic bolus seen with oral therapy (the first-pass effect). Because the liver is a central organ in lipoprotein metabolism, such avoidance of the first-pass effect may reduce nonphysiologic effects on serum lipoproteins.

A transdermal system delivering both estradiol and norethindrone acetate has recently been developed.[5] This regimen provides good cycle control and endometrial protection and prevents osteoporosis.[6, 7] We have now evaluated the effects of this regimen on serum lipoprotein risk factors for cardiovascular disease, using conjugated equine estrogens, the most widely used oral estrogen, as a comparator. Levonorgestrel was used as the oral progestin because it is available in the United Kingdom in a combination calendar pack. We also studied an untreated group to control for temporal changes in serum lipoprotein levels.

Material and methods

Participants. We studied 90 healthy white women before and during transdermal therapy, oral therapy, or no therapy. Women attending the menopause clinic, King's College School of Medicine, for relief of menopausal symptoms were randomized into two treatment arms. Because of concerns of the ethical committee, we were not permitted to randomize women into a placebo arm and instead recruited volunteers not requiring treatment to serve as a reference group.

All women were postmenopausal (between 6 months and 5 years) or, in the case of hysterectomized women, between 6 months and 5 years from the onset of meno-

pausal symptoms. Postmenopausal status was confirmed by measurement of gonadotropin levels. None had undergone castration. All were within 20% of their ideal body weight (Metropolitan Life Tables, 1959). None were taking drugs known to affect lipid metabolism, and none had ever received gonadal steroid pellets (implants), or steroids by any other route within the preceding 6 months. None smoked >10 cigarettes per day or drank >300 gm alcohol per week.

Sixty-one symptomatic women seeking therapy were randomly allocated to receive oral or transdermal therapy, while 29 women were recruited to the reference group. Oral therapy consisted of continuous conjugated equine estrogens (0.625 mg/day) together with *dl*-norgestrel (0.15 mg/day for 12 of each 28 days), supplied as a calendar pack (Prempak C, Wyeth-Ayerst, Maidenhead, England). Transdermal therapy also consisted of 28-day treatment cycles. The pharmokinetics and release characteristics of these patches have been described elsewhere.[5,8] Patches were applied to the buttock or lower abdominal wall and changed twice weekly. For the first 14 days of the cycle, patients applied an estrogen-alone patch (Estraderm TTS 50, Ciba-Geigy, Basel) that delivered 17β-estradiol approximately 0.05 mg/day. For the second 14 days of the cycle they applied a combination patch (Estragest TTS, Ciba-Geigy) that delivered approximately 0.05 mg 17β-estradiol plus 0.25 mg norethindrone acetate per day.

Women attended the Wynn Institute metabolic ward before commencement of the study and then after a further 3 and 6 months. Fasting blood samples were taken at each visit. During month 3, women receiving treatment were studied both at the end of the estrogen-alone phase (cycle 3A, days 12 to 14 with transdermal treatment or days 12 to 15 with oral treatment) and at the end of the combined phase (cycle 3B, days 26 to 28 with both therapies). At the 6-month visit, these women were studied only at the end of the combined phase (cycle 6). Compliance was monitored by serial measurement of gonadotropins and gonadal steroids, by counting used patches and pill packets, and by inspection of bleeding pattern charts completed by those women receiving treatment. Informed written consent was obtained before the study and approval was granted by the Ethical Committees of the Wynn Institute for Metabolic Research and King's College School of Medicine.

Laboratory analyses. Serum samples for lipid and lipoprotein assays were stored at 4° C and analyzed within 4 days; samples for other assays were stored at −20° C and analyzed within 6 months. Plasma concentrations of follicle-stimulating hormone (FSH) and luteinizing hormone (LH) were measured by immunoradiometric assay (MAIAClone, Serono Diagnostics, Surrey, England); plasma estradiol and estrone levels were measured as described previously.[9] Serum total cholesterol and triglycerides were measured by enzymatic assays. HDL and HDL subfraction 3 (HDL_3) cholesterol concentrations were measured after sequential precipitation with heparin and manganese ions[10] and dextran sulfate,[11] respectively. HDL subfraction 2 (HDL_2) cholesterol was calculated as the difference between HDL and HDL_3 cholesterol. Very-low-density lipoproteins (VLDL) were isolated by ultracentrifugation at solvent density 1.006 gm/ml.[12] LDL cholesterol was calculated as total cholesterol minus the cholesterol content of HDL and VLDL. Apolipoproteins AI, AII, and B were measured by immunoturbidimetry.[13] Coefficients of variation for these assays were 1% to 2% for total cholesterol and triglycerides, 2% to 3% for HDL, 5% to 7% for HDL_3, 6% to 8% for HDL_2, and 2% to 4% for apolipoproteins AI, AII, and B.

Statistical analyses. Data that were not normally distributed (estradiol, estrone, triglycerides, VLDL cholesterol, and VLDL triglycerides) were logarithmically transformed before statistical analysis. One-way analysis of variance, two-tailed unpaired Student *t* tests, Kruskal-Wallis one-way analysis of variance, Mann-Whitney U tests, and χ^2 analysis were used as ap-

propriate to compare differences between patient groups, and two-tailed paired Student *t* tests were used to compare changes at each visit with baseline values.

Results

Three of the 61 women receiving treatment withdrew during the study. Two women receiving oral therapy complained of side effects (lower abdominal pain or breast tenderness and migraine) during the combined phase of therapy. One woman receiving transdermal therapy withdrew after experiencing pelvic pain similar to that diagnosed premenopausally as endometriosis. All 29 untreated women completed the study.

Baseline demographic data are shown in Table I. The reference group was slightly older than the oral therapy group, but there was no significant difference in menopausal age. There were no significant baseline differences in blood pressure, parity, alcohol intake, smoking habits, or reported exercise. The reference group had less previous exposure to oral contraceptives ($p < 0.01$). There were no significant changes in body weight during the study.

Both active treatments reduced plasma FSH and LH levels by approximately 50%. Although estradiol levels were increased by both therapies to a similar extent, estrone levels in the oral therapy group were twice as high as those in the transdermal group. Pretreatment estradiol levels in the reference group were marginally lower than those in the treated groups ($p < 0.05$). However, these levels increased at 3 and 6 months ($p < 0.05$), reaching the pretreatment levels seen in the treated groups. Estradiol levels in untreated women remained within the normal postmenopausal range throughout the study. One untreated subject experienced transient recurrence of spontaneous ovarian activity (estradiol level 566 pg/ml) at the 3-

month visit. Data from her 3-month visit were not analyzed.

There were no significant baseline differences in plasma lipids, lipoproteins, or apolipoproteins (Tables II and III). Both therapies lowered serum total cholesterol (Table II, Fig. 1), primarily because of decreases in LDL cholesterol. When the estrogen-alone phase (cycle 3A) was considered, oral therapy produced a significantly greater fall in LDL cholesterol than did transdermal therapy ($p < 0.05$); there were no significant differences between treatments during the combined phases of treatment (cycles 3B and 6). In both treated groups LDL cholesterol levels remained low when progestin was added (cycles 3B and 6). Declines in VLDL cholesterol (Table II) were seen in the transdermal group at all time points and in the oral group during the combined phases of treatment.

Oral treatment had no significant effect on HDL cholesterol during the estrogen-alone phase (cycle 3A), whereas transdermal therapy caused a minor (4%) fall in HDL cholesterol levels at this time (Table II, Fig. 1). During the combined phase (cycles 3B and 6), HDL cholesterol levels fell by 9% to 10% (transdermal therapy) or 5% to 7% (oral therapy). The two HDL subfractions responded differently to treatment (Table II). During the estrogen-alone phase of the treatments there was no significant change in HDL_2 cholesterol, but levels fell by 8% to 10% in both groups when progestin was added during cycle 3B, reverting to pretreatment levels during cycle 6. Levels of HDL_2 cholesterol increased by 14% in the reference group at cycle 3 ($p < 0.05$) but not at cycle 6. During the estrogen-alone phase of therapy, HDL_3 cholesterol fell in the transdermal group only, whereas levels of this lipoprotein were reduced by both therapies during the combined phase of treatment.

Changes in serum apolipoproteins (Table III) supported these observations about LDL and HDL cholesterol. Apolipoproteins B, the principal protein component of LDL, was lowered by both therapies during both phases of treatment, with no significant differences between treatments. During the estrogen-alone phase of treatment (cycle 3A), apolipoproteins AI, the principal protein component of HDL, was lowered by 5% by transdermal therapy ($p < 0.01$) but was unchanged by oral therapy. During the combined phase of treatment (cycles 3B and 6), apolipoproteins AI levels declined by 8% to 10% in the transdermal group ($p < 0.001$) and 4% to 5% in the oral group ($p < 0.05$). The between-treatment difference was significant during cycle 3A ($p < 0.05$) but not during the combined phases. Levels of apolipoproteins AII, a minor protein of HDL predominantly found in the HDL_3 fraction, was unchanged by oral treatment but lowered by 7% to 17% in women receiving transdermal treatment ($p < 0.001$). This between-treatment difference was statistically significant ($p < 0.01$) at all times.

In the estrogen-alone phase (cycle 3A), serum triglyceride levels were increased by 15% with oral therapy but reduced by 18% with transdermal therapy ($p < 0.05$) (Table II, Fig. 1). During the combined phases (cycles 3B and 6), triglyceride levels were reduced by 20% to 25% in both treatment groups. These differences between treatments were reflected in changes in VLDL triglyceride (Table II).

Comment

Both transdermal and oral therapies affected serum lipid and lipoprotein levels. Estrogens and progestins thus have effects on lipoprotein metabolism independent of any hepatic first-pass metabolism. Our findings show that administration of oral progestin, at a dose necessary to prevent proliferative endometrial transformation, does not negate the ability of estrogen replacement therapy to lower levels of LDL, a major cardiovascular risk factor. In addition, we have shown that LDL levels can be lowered substantially by transdermal estrogen replacement therapy and that transdermal progestin does not negate this effect. This would suggest that the effects of estrogen on LDL levels are largely physiologic, rather than representing pharmacologic actions on the liver.

Orally administered estrogen-progestin therapy may have profound effects on serum lipoprotein levels.[2, 14] We are unaware of any published prospective studies of transdermal combined therapy and serum lipoproteins. Reports of the metabolic effects of transdermal estrogen are conflicting. Although Chetkowski et al.[15] found no effects on LDL or HDL, this study was only of 1 month's duration. Another study[16] has shown an increase in HDL (but no change in LDL) with 0.1 mg/day transdermal estradiol, although this was in only 10 women.

The two therapies induced similar plasma estradiol levels. In spite of this, transdermal therapy had less

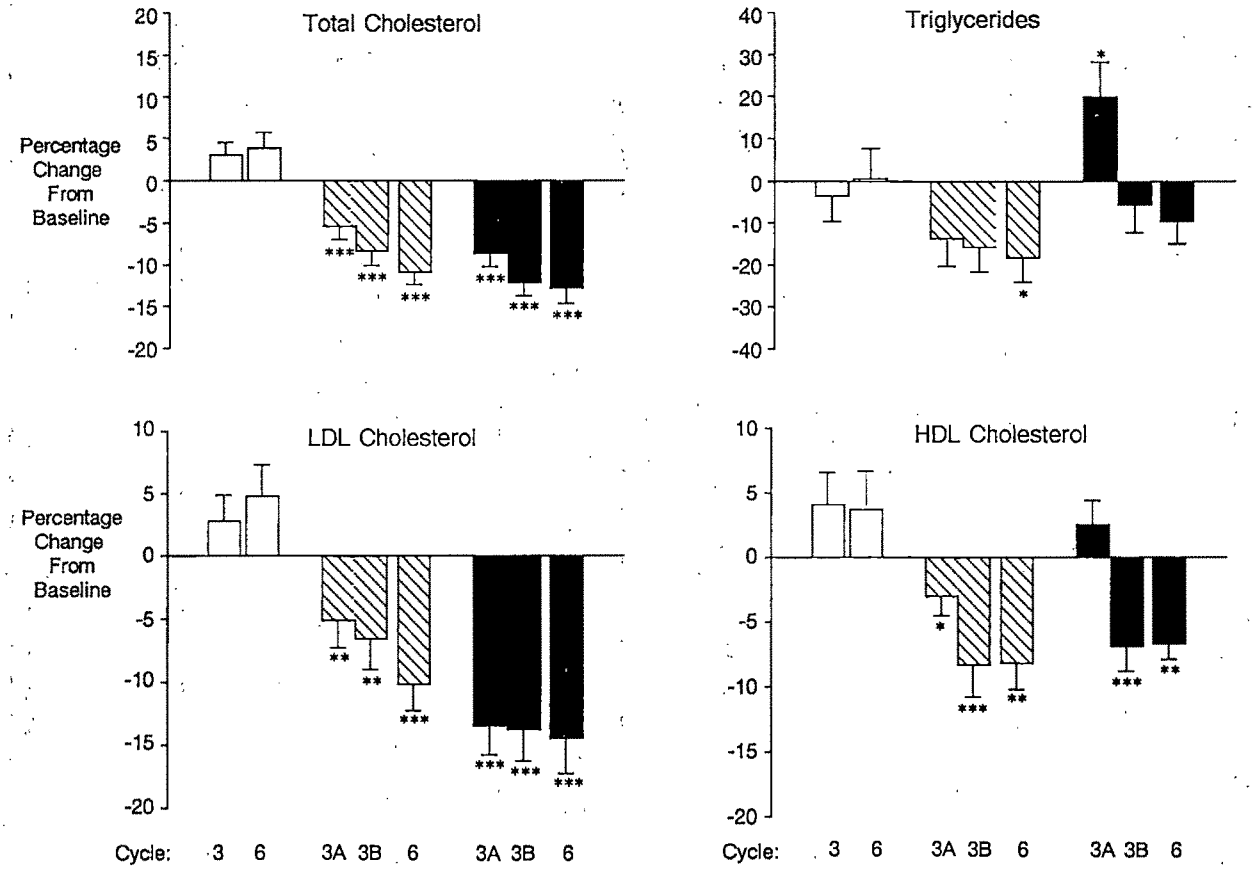

Fig. 1. Changes (mean ± SE) in serum lipids and lipoproteins in untreated subjects *(open bars)* and in subjects receiving either transdermal *(striped bars)* or oral *(solid bars)* estrogen replacement therapy for six cycles. During cycle 3, subjects receiving therapy were studied while taking estrogen alone and combined therapy (cycles 3A and 3B, respectively). During cycle 6, subjects receiving therapy were studied while taking combined therapy. *One asterisk,* $p < 0.05$; *two asterisks,* $p < 0.01$; *three asterisks,* $p < 0.001$; all indicate significant change from baseline value compared with change seen in untreated subjects.

effect on LDL levels than did oral therapy. This could be due to avoidance of the hepatic first-pass effect or to the relative potencies of individual components of the equine preparation. However, it could also be due to the lower plasma estrone levels seen in the transdermal group, because this hormone may lower LDL levels to a greater extent than does estradiol.[17]

We found no significant increase in HDL cholesterol levels in response to oral estrogen, although falls were seen when the progestin was added. This pattern of change was supported by changes in apolipoproteins AI, the major protein component of HDL. Although high doses of conjugated equine estrogens have been reported to increase levels of HDL, this effect is not always found when these steroids are given at a dose of 0.625 mg/day.[14, 18] Where an increase has been seen, addition of progestin may either have no effect, leaving HDL levels elevated, or may oppose the action of the estrogen and reduce HDL levels below baseline, depending on the androgenic characteristics of the progestin and on the balance of estrogen and progestin.[14, 18]

In the transdermal group, HDL levels fell during both combined and estrogen-alone phases, mainly because of falls in HDL_3. Apolipoproteins AII, a minor component of HDL distributed predominantly in HDL_3, was decreased only in the transdermal group, indicating that the fall in HDL_3 was associated with compositional changes in this fraction. Clearly, transdermal administration does not prevent norethindrone from lowering HDL, an observation supporting previous findings with vaginal administration of progestin.[19]

A limited number of studies, virtually all in men, indicate that the HDL_2 subfraction is responsible for the majority of the protective effect seen with HDL.[20] It is this fraction that is selectively increased by oral estrogen.[14, 18] Importantly, we found that the fall in HDL levels induced by both therapies was due primarily to a decrease in the HDL_3 subfraction, with no

consistent change in HDL_2. Such changes in HDL_3 may have a neutral impact on coronary heart disease risk. Interpretation of our HDL subfraction data is confounded by our finding of an increase in HDL_2 cholesterol in untreated women at cycle 3. However, the probability of obtaining a statistically significant change completely as a result of chance is high when a large number of biochemical measurements is performed in a study such as this.

Oral estrogen increased serum triglyceride levels, presumably by increasing the hepatic secretion of triglyceride-rich lipoproteins,[2] whereas oral combined therapy reduced these levels below baseline. A striking finding of the current study is that transdermal therapy lowered triglycerides during both estrogen-alone and combined phases. Although we cannot totally exclude a carryover effect of the progestin, a fall in triglycerides has been reported in women given unopposed percutaneous estradiol.[21] The physiologic effect of estradiol is to lower triglycerides, consistent with the lower triglyceride levels seen in premenopausal women compared with men,[22] and the increased triglyceride levels after ovariectomy.[23] The increase seen with oral estrogens is likely to be a pharmacologic effect, resulting from hepatic first pass. Thus transdermal estradiol appears to be more physiologic than oral estradiol in its effects on triglycerides. The ability of transdermal therapy to lower triglycerides may be important in view of growing evidence that this lipid is an independent risk factor for cardiovascular disease in women.[24]

In terms of cardiovascular risk, the optimal lipoprotein profile for an estrogen-progestin replacement therapy would combine elevated HDL (specifically HDL_2) levels with reduced LDL and reduced triglyceride levels. Our study shows that neither transdermal therapy (17β-estradiol and norethindrone acetate) nor oral therapy (conjugated equine estrogens and *dl*-norgestrel) gives such a profile.

We thank Lee Rogers and Sister Mary Miller for their care of the research patients, Maire Cullinan for technical assistance, and Carl Felton, PhD, for gonadotropin assays. We also thank Danielle Folio and Theo Aschwind (Ciba-Geigy, Basel) for hormone assays and Dr. Lotte Schenkel (Ciba-Geigy) for valuable discussion.

Oral contraceptive type and functional ovarian cysts

Stephan F. Lanes, PhD,[a] Brenda Birmann, BA,[a] Alexander M. Walker, MD, DrPH,[a, b] and Suanne Singer, BA[c]

Chestnut Hill and Boston, Massachusetts, and Augusta, Maine

OBJECTIVE: We tested the hypothesis that multiphasic, low-dose monophasic, and high-dose monophasic oral contraceptives share a common protective effect against functional ovarian cysts.
STUDY DESIGN: We conducted a cohort study using the automatic files of Maine Medicaid to assemble a population of 7462 women between the ages of 15 and 44 who were prescribed an oral contraceptive between Jan. 1, 1987, and Dec. 31, 1988. We included as cases 32 women with a principal diagnosis of a functional ovarian cyst confirmed by medical records as being >20 mm in diameter.
RESULTS: At comparison with the absence of an oral contraceptive prescription, we observed decreasing rates of functional ovarian cysts among women prescribed multiphasic pills (rate ratio 0.91, 95% confidence interval 0.3000 to 2.31), low-dose monophasic pills with ≤35 μg estrogen (rate ratio 0.52, 95% confidence interval 0.17 to 1.33), and high-dose monophasic pills with >35 μg estrogen (rate ratio 0.24, 95% confidence interval 0.01 to 1.34).
CONCLUSIONS: The protective effect of oral contraceptives against functional ovarian cysts reported previously for high-dose monophasic pills may be attenuated with newer pills of lower hormonal potency.
(AM J OBSTET GYNECOL 1992;166:956-61.)

Key words: Oral contraceptives, functional ovarian cysts

Oral contraceptives were introduced in the United States in 1960, and the most popular formulations through the mid-1960s were combination pills containing progestin and >50 μg estrogen.[1, 2] Besides being remarkably effective at preventing pregnancy, these high-dose combination pills also conferred certain health benefits, such as reducing the risk of functional ovarian cysts.[3-5] Publicity arose concerning possible adverse effects, however, and 1967 saw the introduction of low-dose formulations containing ≤35 μg estrogen.[1] Among the unintended effects of the early oral contraceptives was an increased risk of thromboembolic disease, which epidemiologic studies suggested was related to hormonal dose.[6] Possibly as a result of mounting concern about adverse effects, the popularity of the high-dose pills declined through the 1970s.[1, 2] This trend continued into the 1980s with the introduction in 1984 of multiphasic pills, which not only lowered hormone doses but also varied the dosage over the 21-day medication period in an attempt to mimic more closely the natural hormone cycle.[1]

In 1987, Caillouette and Koehler[7] reported on seven women in their clinical practice who were diagnosed with functional ovarian cysts soon after starting to use a multiphasic contraceptive. The hypothesized relation between multiphasic pills and functional ovarian cysts has biologic plausibility because multiphasic pills may not suppress ovarian function to the same degree as pills with higher hormone doses.[8-10] Initial investigation by Grimes and Hughes[11] showed that national trends in sales of multiphasic oral contraceptives were not correlated with hospitalization rates for functional ovarian cysts. Such correlations are of limited use in investigating etiologic relations, however, and even though no relation was apparent, the investigators cautioned that "this indirect assessment can neither confirm nor refute the postulated association."[11]

To date, there have been no measurements of the incidence of functional ovarian cysts among women using multiphasic oral contraceptives. We report here the rate of functional ovarian cysts associated with use of multiphasic pills, low-dose monophasic pills, and high-dose monophasic formulations of oral contraceptives, and we contrast these rates with one another and with the rate of cysts associated with nonuse of oral contraceptives.

Material and methods

We used the automated files of Maine Medicaid to identify a cohort of 9461 women who were prescribed an oral contraceptive from Jan. 1, 1987, to Dec. 31, 1988. We used Medicaid claims data to exclude from the primary analyses women who were not of reproductive age, who had cancer or ovarian dysfunction, or who were given drugs that might interfere with hormone metabolism. These drugs included fertility drugs and hormones, antipsychotics, anticonvulsants, and antitubercular drugs. After exclusions, the study population comprised 7462 women between the ages of 15

and 44 years who contributed person time to the analysis from Jan. 1, 1987, to Dec. 31, 1988, during periods of Medicaid eligibility and when they were not classified as pregnant. To ensure that pregnancy periods were excluded, we excluded periods beginning 36 weeks before until 8 weeks after a delivery and 24 weeks before until 8 weeks after an abortion.

We sought to ascertain first occurrences during the study period of symptomatic functional ovarian cysts >20 mm in diameter. We identified cases from Medicaid billing claims and medical records for ultrasonographic procedures, hospitalizations, and outpatient surgical procedures. We reviewed medical records for hospitalizations and for outpatient surgical procedures that listed an ovarian cyst as a primary or secondary Medicaid diagnosis, but we accepted as cases only those women whose cyst was indicated by the medical record as the primary diagnosis. A diagnostic ultrasonographic procedure is sometimes associated in Medicaid claims data with a presumptive diagnosis. For example, an ultrasonographic procedure performed to rule out ovarian cancer might list ovarian cancer as the billing diagnosis even though the primary diagnosis might be an ovarian cyst. To identify cases diagnosed by ultrasonography but not listed in the claims file, we reviewed radiologists' reports for any pelvic ultrasonographic procedure that had a claim date from 3 months before until 1 week after a medical claim with any diagnosis of functional ovarian cyst. Again, we accepted as cases only those women whose cyst was the principal diagnosis of the ultrasonographic procedure. We defined as cases therefore women with a principal diagnosis of a functional ovarian cyst >20 mm in diameter. Acquisition and initial processing of Medicaid claims data, elicitation of hospital and clinic participation, and medical record abstraction was conducted by Maine Health Information Center.

We computed incidence rates as the number of functional ovarian cysts diagnosed between Jan. 1, 1987, and Dec. 31, 1988, divided by the sum of the person time contributed by the study population over the same period. Oral contraceptives were grouped into four types: multiphasic pills, low-dose monophasic pills (≤35 μg estrogen), high-dose monophasic pills (>35 μg estrogen), and progestin-only pills. Person time was allocated to three temporal categories of drug use: active prescription, recent prescription, and no prescription for an oral contraceptive. Women were considered to have an active prescription beginning on the date of the prescription and continuing for the number of days implied by the amount of medication supplied. Both 21-day and 28-day prescriptions were treated identically as 1 month of medication. We classified person time as recent use during the 30-day period after an active prescription. Any eligible day that did not fall within an active or recent prescription was assigned to the category of no prescription. Each prescription initiated an active prescription classification that truncated the classification in effect at the time of the prescription.

We compared first the rate of functional ovarian cysts during an active prescription for each type of oral contraceptive with the rate during no prescription for an oral contraceptive. Then, to describe differences between pills, we computed effect estimates for each type of oral contraceptive, using multiphasic pills as the reference category. We considered as potential confounding variables age (15 to 24, 25 to 34, 35 to 44), a prescription for antibiotics and duration of oral contraceptive use (≤1 month, >1 to 3 months, >3 to 6 months, >6 months). In the computation of duration of continuous oral contraceptive use, a prescription was considered continuous if it occurred within 5 days after the end of the previous prescription. We assessed and controlled for confounding effects of these variables by standardizing the rate in the reference category according to the covariate distribution in the index (i.e., exposed) category.[12] We also fit regression models to the data under the hypothesis that the observed number of cases follows a Poisson distribution.[13] The results from the regression models were virtually identical to those obtained from the simpler standardized analyses. We measured effects using incidence rate ratios, and we quantified the precision of each rate ratio estimate by computing 95% confidence intervals according to the exact mid-p method.[14]

Results

The study population of 7462 women contributed 179,088 person months, from which we excluded 31,676 person months as pregnancy periods and 50,934 person months as periods of Medicaid ineligibility. We sought medical records for 169 women in the study population, and we obtained records for 155 women. We did not obtain records for 14 women either because we could not find a medical record corresponding to the Medicaid claim (n = 6) or because the claim was from a medical facility from which no records were available (n = 8). Medical records were unavailable for women whose records were located at facilities that were out-of-state (n = 2) or closed (n = 1) or the facilities (or their representatives) decided not to participate for religious (n = 3) or other (n = 2) reasons. Of the 155 women for whom we obtained records, we confirmed 32 women as cases and 113 women as noncases. In addition, we did not include as cases 10 women for whom the medical records contained insufficient information to classify one way or the other according to our case definition.

To assess prescription claims as an indicator of drug use, we computed effect estimates on pregnancy for each oral contraceptive category (Table I). After comparison with periods when no oral contraceptive was

≤35 μg estrogen	5	22,251.6	2.2
>35 μg estrogen	1	8,385.6	1.2

prescribed, these data show an approximate 65% reduction in the pregnancy rate for women prescribed multiphasic, low-dose monophasic, and high-dose monophasic pills and a 56% reduction for women taking progestin-only pills. Pregnancy rates declined with increasing duration of use, and there was a 75% reduction in the pregnancy rate after 6 months of continuous oral contraceptive prescriptions.

Table II describes the distribution of cases, person time, and incidence rates of functional ovarian cysts according to oral contraceptive category. The distribution of person time was divided nearly evenly between an active prescription (46%) and no prescription (45%) for an oral contraceptive, with the remaining time classified as recent use of oral contraceptives. Among types of oral contraceptives, the distribution was similar to national market shares[2]: 50% low-dose monophasic pills, 30% multiphasic pills, 18% high-dose monophasic pills, and <0.5% progestin-only minipills. Owing to sparse data, the progestin-only minipill is omitted from subsequent analyses of cysts. We confirmed 32 cases of functional ovarian cysts, with 19 cases occurring during no oral contraceptive prescription, two cases during the recent prescription period, and 11 cases during an active prescription.

After adjustment for slight confounding effects of age, comparisons with no oral contraceptive prescription revealed a 9% reduction in the rate of cysts for women using multiphasic pills, a 48% reduction in the rate among women using low-dose monophasic pills, and a 76% reduction in the rate for users of high-dose monophasic pills (Table III). In consideration of the hypothesis that these successive reductions in risk correspond to pills with increasing ovarian suppression, we conducted a regression analysis that used the information in each category simultaneously. The regression line for the multiplicative trend in the rate of cysts across these oral contraceptive categories has a slope of 0.76 (p value = 0.10), indicating progressive decline in the incidence of ovarian cysts with increasing ovarian suppression.

Among oral contraceptive categories, we used multiphasic pills as the reference category because the category with the lowest incidence rate, high-dose monophasic pills, included only one case. Compared with the incidence rate among women prescribed multiphasic pills, the rate of cysts among women using low-dose monophasic pills is approximately 40% lower (rate ratio 0.60, 95% confidence interval 0.16 to 2.16), and the rate of cysts among women using high-dose monophasic pills is about 67% lower (rate ratio 0.33, 95% confidence interval 0.01 to 2.54). Equivalently, the rate of functional ovarian cysts among women prescribed multiphasic pills is about 1.7 times greater than the rate among women prescribed low-dose monophasic pills and three times greater than the rate among women prescribed high-dose monophasic pills.

We examined the relation between rates of ovarian cysts and duration of continuous oral contraceptive prescription (Table IV). These data are sparse but show that among women with an active prescription for any type of oral contraceptive the overall incidence of functional ovarian cysts declines with increasing duration of use. The trends are not identical, however, for each type of oral contraceptive. For both low-dose and high-dose monophasic pills, the rate of cysts decreases with each category of increasing duration. For high-dose pills, the only case occurred during the 2231 person months accumulated during the first month of use, whereas no cases occurred during the subsequent 6154 person months. This trend is consistent, however, only for the monophasic pills. The rate of cysts among women using multiphasic pills declines in the duration category of >1 month and ≤3 months, then increases slightly with increasing duration.

Comment

In this population of women prescribed oral contraceptives, the incidence rate of functional ovarian cysts was greater during periods when no oral contraceptive was prescribed than it was during an active prescription for either monophasic pills or multiphasic pills. For users of oral contraceptives, however, this preventive effect against functional ovarian cysts appears to be

greater for monophasic pills—especially high-dose pills—than for multiphasic pills. Two limitations of this study are its small size in relation to the frequency of functional ovarian cysts and the possibility of selective diagnosis of cysts among users of multiphasic oral contraceptives.

Misclassification of oral contraceptive use probably resulted in some underestimation of the effects of oral contraceptives on functional ovarian cysts. Because the inaccuracy of prescription data as a marker of drug use should apply similarly to each oral contraceptive category and to cases and noncases alike, misclassification of this type would be expected to diminish any apparent association.[15]

To investigate the extent of misclassification of oral contraceptive use, we examined the intended effects of oral contraceptives in reducing pregnancy rates. Compared with no oral contraceptive prescription, the pregnancy rate was reduced by approximately 65% for women with prescriptions for multiphasic, low-dose monophasic, or high-dose monophasic pills and about 56% for women using progestin-only pills. In addition, there was a trend toward decreasing pregnancy rates with increasing duration of oral contraceptive use, so that the pregnancy rate declined by about 75% after 6 months of use. The similar efficacy of monophasic and multiphasic pills,[16] the lower efficacy of progestin-only pills,[16] and the trend of increasing efficacy with duration of use[17, 18] have been suggested previously but cannot account entirely for the apparent efficacy of oral contraceptives being less than expected. Although the contraceptive effect is apparent in these data, the relatively large number of pregnancies suggests that a lack of compliance resulted in substantial underestimation of oral contraceptive efficacy, perhaps by as much as 35%. Nevertheless, this form of misclassification would not cause the appearance of an association where none existed and would not explain the association between oral contraceptive type and functional ovarian cysts.

Another potential source of exposure misclassification derives from the possibility that oral contraceptives were prescribed to treat a functional ovarian cyst. We examined oral contraceptive histories of all exposed cases to determine if any women were first prescribed the oral contraceptive type within a few months of the diagnosis. We identified one such case who was prescribed high-dose monophasic pills shortly before being diagnosed with a functional ovarian cyst. If the cyst was suspected and treated before the diagnosis, then this case should have been classified as having no oral contraceptive prescription. The effect of this bias would be to overestimate the incidence rate of ovarian cysts in the category of high-dose monophasic pills. Thus therapeutic use of oral contraceptives to treat ovarian cysts would not explain high-dose monophasic pills being associated with the lowest rate of ovarian cysts.

Misclassification of disease status is another potential source of error in this study. In particular, functional ovarian cysts are difficult to diagnose, and there may be a large group of occult cases that does not come to medical attention. Moreover, suspicion about a possible relation between multiphasic pills and functional ovarian cysts[7] could have resulted in cases being diagnosed preferentially among users of multiphasic pills. We addressed this issue by attempting to ascertain only symptomatic cases. We note also that physicians performing diagnostic procedures such as ultrasonographic examinations would not necessarily be aware of a patient's oral contraceptive history. Although we cannot rule out

a diagnostic bias, two lines of evidence run counter to this hypothesis. First, a suspicion concerning ovarian cysts and multiphasic pills should not apply to low-dose monophasic pills, because there has been no suggestion of a relation between ovarian cysts and low-dose monophasic pills. Thus the finding of a higher rate of cysts among users of low-dose monophasic pills than among users of high-dose monophasic pills should not be due to diagnostic bias. Second, any diagnostic bias for users of multiphasic pills should exist as soon as multiphasic pills are prescribed and might be expected to diminish with continued contraceptive use as the susceptible population is diagnosed and switched from multiphasic pills to other forms of contraception. During the first month of use, however, the results show little difference between types of oral contraceptives in the rate of cysts (Table IV). After the first month of use, the rate of cysts declines for users of monophasic contraceptives. For users of multiphasic pills, however, the rate of cysts declines briefly, but then increases with increasing duration of use. Thus the difference between pill types in the risk of functional ovarian cysts is enhanced with increasing duration of use. Rather than indicating a diagnostic bias, these data suggest that, like the pregnancy data, categories of longer duration of oral contraceptive use provide a more accurate indication of pharmacologic effects.

We controlled by either restriction or analytic means for potential confounding effects of age and duration of oral contraceptive use, for a variety of drugs that might affect hormone metabolism, and for the effects of cancer and ovarian dysfunction. Smoking data were unavailable from Medicaid, and we did not control for a possible effect of smoking. Smoking has been reported to be associated with an increased risk of ovarian cysts.[19] The reported effect was small, however, with the rate of cysts among current smokers being 50% greater than the rate among never-smokers. This difference could account for the difference in the rate of cysts between high-dose and low-dose monophasic pills or between low-dose monophasic and multiphasic pills, but it could not account for the threefold difference between multiphasic and high-dose monophasic pills even if everyone using multiphasic pills smoked and no one using high-dose monophasic pills smoked. It is possible that the effects of smoking are greater than has been estimated, but it is also unlikely that there is a great disparity in the prevalence of smoking among users of different types of oral contraceptives.

One reason that we restricted the cohort to women using oral contraceptives and did not include a comparison group of nonusers was to reduce differences between comparison groups with regard to extraneous risk factors (i.e., confounding). Within the cohort of oral contraceptive users, we selected as the primary reference category periods of no prescription because this category provided the most statistically stable effect estimates. If the protective effect of oral contraceptives lasts for longer than 1 month, then the rate observed here for the category of no prescription underestimates the true risk in the absence of oral contraceptives. This source of error, combined with the likelihood that some women did not use their prescribed oral contraceptives or did not use them properly, would bias rate ratio estimates toward a finding of no association. Thus the small decline in the rate of functional ovarian cysts observed for women prescribed multiphasic pills compared with no oral contraceptive is likely to underestimate the protective effect of multiphasic pills. Nevertheless, the possibility that multiphasic pills increase the risk of cysts compared with no oral contraceptive cannot be dismissed.

This is only the first study to investigate the risk of functional ovarian cysts in relation to multiphasic and other types of oral contraceptives. In addition, functional ovarian cysts are uncommon, and the small number of cysts in this study renders the incidence rates unstable and the effect estimates imprecise. Consequently, any or all of the differences between contraceptive types in the rate of ovarian cysts could be due to chance. To the extent that the categories of oral contraceptives used in this analysis correspond to different levels of ovarian suppression, however, this possibility becomes increasingly remote. The issue is best addressed, of course, by additional studies.

We thank Maine Medicaid for providing access to their data, the Maine Health Information Center for facilitating the acquisition and processing of Medicaid data and medical records, and Maggie Satterfield and Noreen Manzo for their assistance in conducting the research.

Bound volumes available to subscribers

Bound volumes of the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY are available to subscribers (only) for the 1992 issues from the Publisher, at a cost of $68.00 for domestic, $95.76 for Canada, and $91.00 for international for Vol. 166 (January-June) and Vol. 167 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the JOURNAL name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, USA; phone (800) 325-4177, ext. 4351, or (314) 453-4351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular JOURNAL subscription.

Plasma endothelin levels in preeclampsia: Elevation and correlation with uric acid levels and renal impairment

Barbara A. Clark, MD, Lisa Halvorson, MD, Benjamin Sachs, MD, and Franklin H. Epstein, MD

Boston, Massachusetts

OBJECTIVE: The purpose of this study was to determine if endothelin levels are elevated in women with preeclampsia and if these levels correlated with other laboratory features of disease severity.

STUDY DESIGN: Parameters were compared in four groups of women volunteers by means of analysis of variance: (1) 16 women with preeclamptic pregnancies, (2) 11 pregnant women without preeclampsia, of similar lengths of gestation, (3) six otherwise normal women with pregnancies at term or beyond (>38 weeks), and (4) 22 normotensive young women.

RESULTS: Endothelin levels were elevated in women with preeclampsia as compared with those of gestation-matched pregnant and nonpregnant controls (22.6 ± 2.0 vs 12.0 ± 1.0 vs 10.4 ± 1.3 pmol/L, $p < 0.005$, preeclampsia vs controls) and also were increased in late gestation (17.7 ± 2.0 pmol/L). Endothelin correlated positively with plasma levels of uric acid ($r = 0.698$, $p < 0.005$) and inversely with creatinine clearance ($r = -0.659$, $p < 0.05$).

CONCLUSION: Circulating endothelin levels are elevated in women with preeclampsia and correlate closely with serum uric acid levels and measures of renal dysfunction. These observations suggest that endothelin may contribute to renal vasoconstriction in preeclampsia. (Am J Obstet Gynecol 1992;166: 962-8.)

Key words: Endothelin, preeclampsia, uric acid

Endothelin is a potent endogenous vasoconstrictor peptide produced by endothelial cells.[1] It is thought to participate in the regulation of vascular tone, but its normal physiologic and pathophysiologic role is unknown. Endothelin infusion into animals increases vascular resistance and decreases renal perfusion and glomerular filtration.[2-5] High-affinity binding sites for endothelin have been found in the placenta, and high levels of endothelin have been noted in umbilical vessels and fetal blood.[6-9]

Prominent features of preeclampsia include hypertension and impaired renal function with decreased uric acid excretion and glomerular endothelial cell injury.[10, 11] The mediators of these changes remain uncertain. To determine if endothelin levels are elevated in women with preeclampsia and if these levels correlate with other clinical and laboratory features that have been previously associated with the severity of this disease, we studied normotensive women and women with normal and preeclamptic pregnancies. We report elevated endothelin levels in preeclampsia and a close association between these levels and measures of renal dysfunction.

Methods

We examined four groups of women volunteers: (1) 16 pregnant women with preeclampsia at 27 to 38 weeks' gestation (age 20 to 40 years), (2) 11 pregnant women at similar stages of gestation (27 to 38 weeks) without preeclampsia (age 22 to 38 years), (3) six otherwise normal women with pregnancies at term or beyond (>38 weeks), and (4) 22 normotensive, nonmedicated healthy nonpregnant women (age 21 to 42 years). There were no preeclamptic pregnancies >38 weeks of gestation. None of the women was in labor at the time of study. Medical history and physical examination were performed at the time of phlebotomy. Three of the preeclamptic women were receiving intravenous magnesium sulfate, but none of the subjects were on any other antihypertensive medication at the time of study. The criteria for the diagnosis of preeclampsia were the appearance during the last trimester of ele-

6/1/33771

vated blood pressure (≥130/90 mm Hg), edema, elevated plasma level of uric acid (>5.0 mg/dl), and proteinuria (≥1+ on dipstick, approximately 30 mg/dl). One additional patient was included with only trace proteinuria but who met all other criteria. At the time of entry into the study, all women had blood samples obtained for endothelin, atrial natriuretic peptide (ANP), plasma renin activity, aldosterone, creatinine, and uric acid, and urine protein was assessed by dipstick. In addition, 11 of the 16 preeclamptic women and eight of the 11 normal pregnant women had 24-hour urine collections for total protein excretion and creatinine clearance. The preeclamptic women also had evaluation of liver function tests, platelet count, prothrombin and partial thromboplastin times, albumin, and hematocrit.

All studies were approved by the Committee on Clinical Investigation, New Procedures and New Forms of Therapy at the Beth Israel Hospital.

Blood samples for endothelin and ANF were collected into prechilled test tubes containing disodium ethylenediaminetetraacetic acid (1.5 mg/ml) and aprotinin (Trasylol, 400 kallikrein inhibitor units per milliliter; FBA Pharmaceuticals, New York). Blood was immediately centrifuged at 4° C. One milliliter of plasma was used for endothelin assay and 3 ml was used for ANP assay. Immediately after separation, plasma was acidified (0.25 ml 2N hydrochloric acid per milliliter plasma), extracted over ODS-silica cartridges (Sep-pak C18, Waters Associates, Milford, Mass.), washed with a solution of trifluoroacetic acid, and eluted with acetonitrile. Eluates were then lyophilized and stored at −20° C until just before radioimmunoassay (RIA). RIA for α-human ANP was performed as previously described with reagents obtained from Amersham, United Kingdom.[12] The lower limit of assay detection was 15.4 pmol/L (5.1 pg/ml), and the intraassay and interassay coefficients of variation were 6.7% and 10.8%, respectively.

Samples for endothelin were reconstituted in 250 μl of 0.02 mol/L borate buffer just before assay. RIA was performed with a standard double-antibody precipitation technique with reagents obtained from Amersham. Antiserum was specific for endothelin-1 and endothelin-2, with 30% cross-reactivity with Big endothelin and without cross-reactivity with endothelin-3 or ANP. After addition of antibody and trace to 100 μl of sample, tubes were again incubated at 4° C. After 72 hours, goat antirabbit antiserum (dilution 1:8) (Pel-Freez, Rogers, Ark.) was added and incubation was continued an additional 24 hours. Bound from free radioactivity was then separated by centrifugation at 4° C for 30 minutes at 3200 rpm with subsequent decantation of the supernatant. Bound radioactivity was determined by counting each tube for 2 minutes in a γ-scintillation counter. The sensitivity as determined by 50% displacement of tracer was approximately 20 fmol per tube. The lower limit of assay detection was 1 fmol per tube. The intraassay and interassay coefficients of variation were 7% and 15%, respectively.

Plasma renin activity was determined by RIA of the generation of angiotensin I with kits purchased from Baxter, Cambridge, Mass. Serum aldosterone was determined with RIA kits purchased from Diagnostics Products Corporation, Los Angeles.

Creatinine determinations were performed in the clinical laboratory with a rate-dependent modification of the Jaffe reaction that minimizes the influence of slow-reacting chromogens (SMAC II, Technicon Instruments, Inc., Tarrytown, N.Y.).

All other laboratory evaluation was performed in the clinical chemistry and hematology laboratories at the Beth Israel Hospital.

Statistics. Power analysis that was based on preliminary endothelin measurements (with the β error set at 0.8 and the significance level at 0.05) suggested that, on average, seven subjects should be enrolled in each group. Statistical analysis was performed with one-way analysis of variance and determination of Pearson's correlation coefficients. Values were considered statistically significant at a p value of <0.05. All values are expressed as mean ± standard error.

Results

Subject characteristics (Table I). All but one of the preeclamptic women were primigravid; all of the controls were primigravid. Arterial blood pressures were highest in the preeclamptic group and lowest in the pregnant controls (mean arterial pressure 111.7 ± 2.5 vs 77 ± 1.5 vs 83.5 ± 2.3 mm Hg, systolic pressure 144 ± 3.5 vs 102 ± 3 vs 114 ± 2 mm Hg, diastolic pressure 95 ± 2.4 vs 64 ± 2 vs 70 ± 2; preeclampsia vs pregnant and nonpregnant controls $p < 0.05$). The mean duration of gestation was similar in both the women with preeclampsia and pregnant controls (34.3 ± 0.8 vs 32.8 ± 1.1 weeks). There were six twin gestations in the preeclamptic group and none in the pregnant control group. The mean duration of gestation in the preeclamptic twin pregnancies (33 ± 1.6 weeks) was not different from that in the singleton preeclamptic pregnancies (35 ± 0.9 weeks).

Clinical laboratory features (Table I). As anticipated, the preeclamptic group had higher uric acid levels than the normal pregnant women. They also had higher serum creatinine levels. The average 24-hour urine creatinine clearance was 103 ± 5 ml/min, and protein excretion was 1.67 ± 0.57 gm/day in the 11 preeclamptic patients in whom it was measured. The average 24-hour creatinine clearance and 24-hour protein excretion was normal in the eight normal pregnant women

Table I. Subject characteristics of preeclamptic group and normal pregnant subjects

	Preeclamptic	*Normal pregnant*
No.	16	11
Gestation (wk)	34.3 ± 0.8	32.8 ± 1.1
Age (yr)	30.6 ± 1.8	31.5 ± 1.5
Arterial blood pressure (mm Hg)	112 ± 2	77 ± 2*
Uric acid (mg/dl)	7.1 ± 0.3	3.8 ± 0.2*
Serum creatinine (mg/dl)	1.0 ± 0.03	0.74 ± 0.03*
Creatinine clearance (ml/min)	103 ± 5 (n = 11)	126 ± 6 (n = 8)*
Protein excretion (gm/24 hr)	1.67 ± 0.57	0.20 ± 0.05*
Hematocrit (%)	35 ± 1.5	35.4 ± 1.0 (n = 7)
Platelet count (cells × 10^3/mm^3)	184 ± 17	201 ± 15 (n = 7)

Values are mean ± SD. Subjects were similar in age and gestational duration but had significant differences in blood pressure, uric acid, serum creatinine, creatinine clearance, and protein excretion.

Table II. Peptide and hormone levels in preeclampsia, normal pregnancy and nonpregnancy

	Preeclampsia	*Normal pregnancy*	*Nonpregnancy*
Endothelin (pmol/L)	22.6 ± 2.0*	12.0 ± 1.0	10.4 ± 0.4
ANP (pmol/L)	93 ± 36	55 ± 8	53 ± 3
Plasma renin activity [ng/(L · sec)]	3.4 ± 1.1†	2.8 ± 0.6†	0.7 ± 0.1
Aldosterone (pmol/L)	1395 ± 261‡	2665 ± 350†	652 ± 78

*$p < 0.005$, versus normal pregnancy and nonpregnancy.

†$p < 0.05$, versus nonpregnancy.

‡$p < 0.05$, versus normal pregnancy.

in whom it was measured. There was also a trend toward lower platelet counts in the preeclamptic patients, although this did not reach the level of statistical significance. Three of the patients with preeclampsia had elevated values on liver function tests.

Endothelin levels (Table II). Endothelin levels were highest in the women with preeclampsia, 22.6 ± 2.0 pmol/L ($p < 0.005$), as compared with the normal pregnant women (12.0 ± 1.0 pmol/L) and the nonpregnant controls (10.4 ± 0.4 pmol/L). The levels in the preeclamptic twin pregnancies (24.3 ± 3.6 pmol/L) were not different from those in the singleton preeclamptic pregnancies (21.6 ± 2.4 pmol/L). The levels in the normal pregnant women were not different from those of the nonpregnant women.

ANP, aldosterone, and renin levels (Table II). Although ANP levels tended to be highest in the preeclamptic group, levels were not significantly different in any of the groups (93 ± 36, 55 ± 8, and 53 ± 3 pmol/L in preeclamptic group, pregnant group, and nonpregnant controls, not significant). However, there was greater variability in ANP levels in the preeclamptic group: three were low (<20 pmol/L), nine were normal (20 to 90 pmol/L), and three were abnormally high (126, 412, and 474 pmol/L). One did not have ANP measured. In contrast, ANP levels in the normotensive pregnant women were normal in 10 (30 to 85 pmol/L) and slightly high in one (120 pmol/L). The range of ANP levels was 35 to 75 pmol/L in the nonpregnant women and 23 to 79 pmol/L in the late-gestation group.

Aldosterone levels in the preeclamptic group were significantly lower than those in the normal pregnant women, although still higher than those of the nonpregnant women.

Plasma renin activity was similarly elevated in both pregnant groups as compared with that in nonpregnant controls.

Correlation analysis (Fig. 1). In patients with preeclampsia but not in controls, endothelin levels were strongly positively correlated with uric acid levels ($r = 0.698$, $p < 0.005$, $y = 0.1257x + 4.49$). Endothelin was also positively correlated with serum creatinine ($r = 0.595$, $p < 0.05$, $y = 0.0136x + 0.668$) and inversely correlated with creatinine clearance ($r = -0.659$, $p < 0.05$, $y = -1.457x + 135$). There was no correlation with blood pressure or 24-hour protein excretion.

ANP levels were directly correlated with mean arterial blood pressure ($r = 0.571$, $p < 0.05$) in the preeclamptic group but not in the control groups. There was no significant correlation between ANP levels and endothelin, creatinine clearance, serum creatinine, serum albumin, hematocrit, aldosterone, plasma renin activity, or multiple gestation.

Influence of duration of gestation (Fig. 2). To determine if length of gestation influenced endothelin levels, six primigravid women with otherwise normal pregnancies but who were late in gestation (>38 weeks) were also evaluated. The mean duration of gestation in these women was 39.8 ± 0.5 weeks. The mean ar-

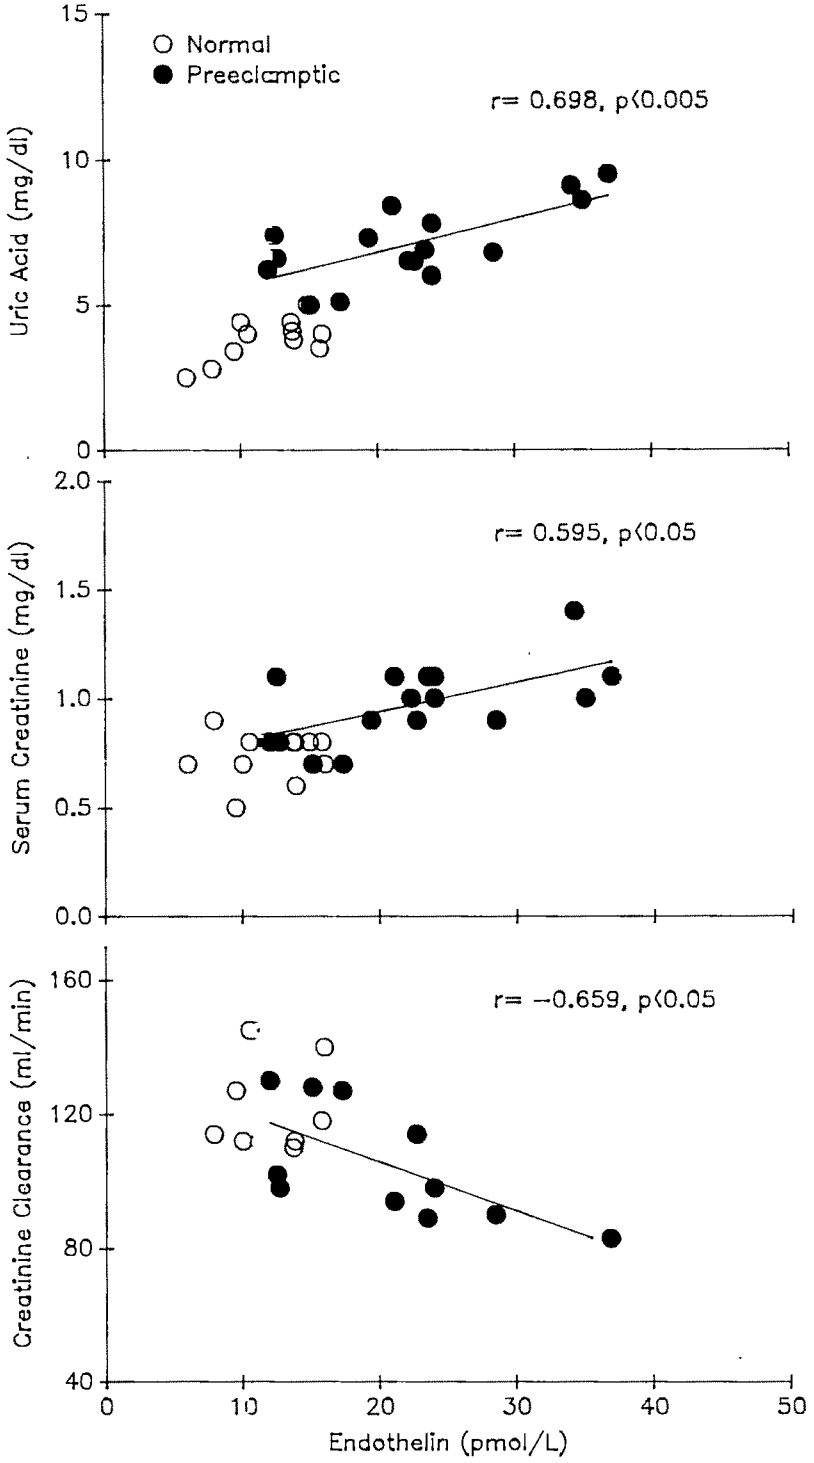

Fig. 1. Endothelin levels correlated significant with uric acid ($r = 0.698, p < 0.005$), serum creatinine ($r = 0.595, p < 0.05$), and creatirine clearance ($r = -0.659, p < 0.05$) in preeclamptic group *(closed circles)* but not in normal women *(open circles)*.

terial blood pressure was 76 ± 2 mm Hg. Endothelin levels averaged 17.7 ± 2.0 pmol/L, higher than those of the normal women of 27 to 38 weeks' gestation ($p < 0.05$) and lower than those of the preeclamptic group of 27 to 38 weeks' gestation, although this did not reach the level of statistical significance. Uric acid levels were 4.8 ± 0.4 mg/dl, higher than those of the earlier gestation normal women ($p < 0.05$) and lower than those of the women with preeclampsia ($p < 0.05$). Endothelin levels correlated positively with weeks of

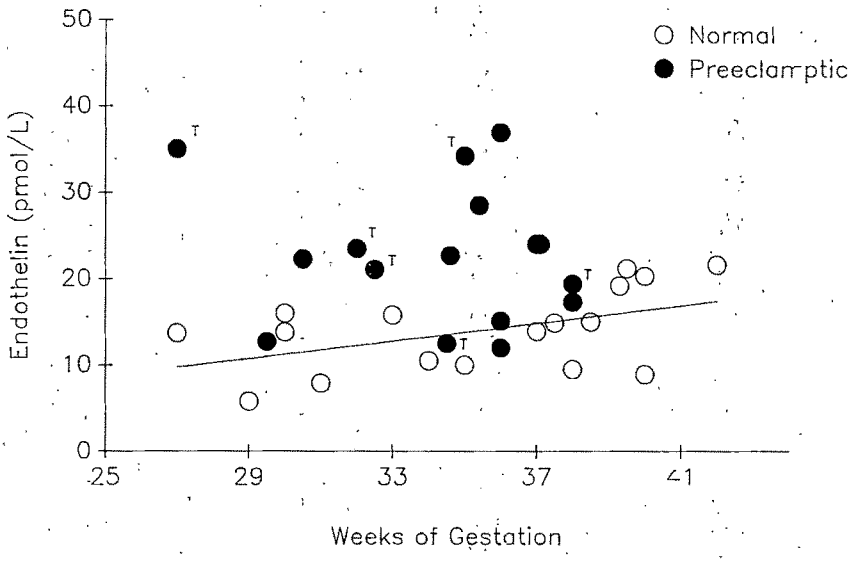

Fig. 2. Influence of weeks of gestation on endothelin levels. For any given gestational duration, endothelin levels were higher in preeclamptic group *(closed circles)* and rose significantly with length of gestation in normal pregnant women *(open circles)* ($r = 0.492$, $p < 0.05$). *T*, Twin gestation.

gestation over the third trimester in the 17 normal primigravid women ($r = 0.492$, $p < 0.05$). There was no correlation of endothelin levels with weeks of gestation in the preeclamptic group, although there were no women with preeclampsia beyond 38 weeks' gestation.

Comment

This study demonstrates elevated endothelin levels in women with preeclampsia compared with pregnant women of similar gestational duration without preeclampsia and with healthy, young, nonpregnant controls. Since the institution of this study there has been at least one other report of an increase in endothelin levels in women with preeclampsia.[13] However, the relevance of endothelin to the changes in renal function, urate resorption, and blood pressure seen in preeclampsia has not previously been examined. Endothelin levels in preeclamptic women had an especially close correlation to the serum uric acid level, serum creatinine, and creatinine clearance but did not correlate with mean arterial blood pressure or degree of proteinuria. Endothelin levels also seem to increase with gestational duration during the third trimester, with the major increase occurring close to the estimated delivery date.

For several reasons, the circulating level of endothelin is probably an imprecise guide to its physiologic role. We found a close correlation between endothelin and serum creatinine and creatinine clearance in preeclamptic women, suggesting but not proving a causal relationship. It seems possible that endothelin may be responsible in part for the reduction in glomerular filtration rate by increased renal vascular resistance. The kidney is appreciably more sensitive than other vascular regions to the vasoconstrictor effects of endothelin.[14] In animal experiments[15] and in the isolated kidney,[5] levels of endothelin (40 to 80 pmol/L) close to those found in women with preeclampsia are associated with renal vasoconstriction. In our laboratory infusion of low doses of endothelin into rats, to produce plasma levels of 15 to 30 pmol/L above basal levels, were capable of reducing renal perfusion approximately 25% (unpublished observations).

High-affinity binding sites for endothelin-1 have been demonstrated in both the glomerular and the placental circulations.[6-9, 16] Furthermore, sustained elevations in vascular resistance persist after endothelin infusion, long after circulating levels have returned to baseline, suggesting prolonged binding of endothelin to its receptors.[2-4] Therefore it is possible that even lower circulating plasma levels may have pathophysiologic significance. The observation of elevated endothelin levels and their correlation to measures of renal dysfunction, coupled with the presence of high-affinity binding sites for endothelin in the uteroplacental and glomerular circulation, suggest that endothelin may contribute to the declining renal function and diminished placental perfusion that are characteristic of preeclampsia.

A classic feature of the preeclamptic state is an elevated plasma level of uric acid, which is generally predictive of severity of disease[17, 18] and is closely correlated

with the glomerular endothelial hyperplasia characteristic of preeclampsia.[10] In the current study endothelin levels had a remarkably close correlation with plasma uric acid levels. Elevated uric acid levels in preeclampsia are thought to be the result of a decrease in uric acid clearance that is disproportionate to the fall in glomerular filtration rate.[11] The effect of endothelin on uric acid clearance in humans has not been measured; however, other vasoconstrictors, such as angiotensin II and norepinephrine,[19] have been shown to increase urate resorption, and endothelin might have a similar effect. Furthermore, endothelin has been recently shown to increase proximal tubule fluid reabsorption, the site of uric acid reabsorption.[20]

High levels of endothelin have been reported in umbilical vessels and fetal blood.[6-9] It has been postulated that endothelin may be important in the vasoconstriction of placental and umbilical vessels at the time of delivery, to prevent excessive blood loss.[6] If this were true, one might expect circulating endothelin levels to increase near the end of gestation. Indeed, we did find a positive correlation between weeks of gestation and endothelin levels in normal primigravid women. The presence of mildly elevated endothelin levels near term in normal pregnancy without evidence of vasoconstriction suggests that endothelin is unlikely to be the only variable contributing to renal vasoconstriction. There are clearly factors, such as enhanced platelet aggregability, diminished prostacyclin production, increased thromboxane levels, and other unknown variables, that may contribute to the difference in vasoconstrictive manifestations.

In the current study women with preeclampsia showed wide variability in ANP levels, a direct correlation between ANP levels and mean arterial blood pressure in the preeclamptic group, and no significant differences in levels between pregnant and nonpregnant women. Other studies of ANP levels in pregnancy report little difference between normal pregnant and nonpregnant controls, modestly higher levels in preeclampsia than in normal pregnancy, and positive correlations between ANP level and blood pressure.[21-25] Therefore, in spite of the well-known physiologic hypervolemia of pregnancy, ANP levels do not appear to be uniformly elevated.

In summary, circulating plasma endothelin levels are elevated in preeclampsia as compared with normal pregnancy and nonpregnancy. These levels are closely correlated with markers of disease severity and deteriorating renal function such as plasma urate, serum creatinine, and creatinine clearance. Endothelin levels also appear to rise late in gestation in normal pregnant women. Endothelin may be involved in the systemic vasoconstriction, reduction in renal and placental blood flow, and elevated plasma urate levels associated with preeclampsia.

We thank Craig West, BS, and Todd Parker, BS, for their technical assistance.

Latex anaphylaxis in an obstetrics and gynecology physician

M. Dwight Chen, MD, Jeffrey S. Greenspoon, MD, and Toni L. Long, MD
Los Angeles, California

Latex anaphylaxis caused by surgical gloves developed in a physician with a history of urticaria to latex. Standard therapy with epinephine and fluids was effective. Latex allergy should be included in the differential diagnosis for anaphylaxis in a patient or a physician. (AM J OBSTET GYNECOL 1992;166:968-9.)

Key words: Anaphylaxis, latex, health care worker

Allergic reactions to latex are recognized with increasing frequency among health care workers.[1] We report a case of latex anaphylaxis developing in an obstetrician-gynecologist.

Case report

A 30-year-old resident physician in obstetrics and gynecology had a history of allergic reactions to latex-containing gloves. At age 16 contact dermatitis developed while she was wearing latex gloves as a nurse's aide. During medical school the allergic reaction progressed to local contact urticaria and mild systemic symptoms consisting of anxiety and dysphoria. The symptoms were controlled by the use of cotton and vinyl liners worn under the gloves. She had a history of eczema, allergic rash to ibuprofen, and allergic rhinitis. She had no other medical conditions.

6/1/34369

During her residency she was called to perform an emergency vaginal breech delivery. She put on latex gloves without the protective liners because of the urgency of the situation. During repair of the episiotomy, localized pruritus gradually developed on the hands, and she experienced dyspnea, tachypnea, extreme anxiety, dysphoria, and confusion. She removed the gloves after the repair was completed. Generalized erythema and swelling developed. Blood pressure was 70/30 mm Hg, pulse 110 beats/min, and respirations 30 breaths/min. (Normal values are blood pressure 110/60 mm Hg and pulse of 60 beats/min.) A capillary blood glucose level was 81 mg/dl. Anaphylactic shock was diagnosed. Standard treatment with vigorous intravenous fluid and two doses of epinephine 1:1000 concentration, 0.3 mg, was administered subcutaneously. The physician was transferred to the emergency room during the course of therapy. In addition, 50 mg diphenhydramine was given intramuscularly and 5 mg diazepam intravenous. The episode gradually resolved over a 3-hour period.

Skin testing confirmed a hypersensitivity reaction to latex. The physician now routinely uses nonlatex hypoallergenic gloves (Elastyren, Danpren, Denmark; Tactylon, Smartpractice, Phoenix). There has been no recurrence with this preventative measure.

Comment

The increasing use of latex gloves to protect health care workers is likely to be responsible for the increase in exposure and allergy to latex. Hypersensitivity to rubber products, including latex, has been recognized for more than a decade.[2] The allergic reaction may range from local contact dermatitis to anaphylaxis. The urticaria and anaphylaxis are immunoglobulin E mediated; the antibody may be directed either to latex itself or toward the chemicals used in the vulcanizing process.

The treatment of latex anaphylaxis does not differ from the treatment of anaphylaxis of other causes. Essential therapy consists of three measures:

1. Epinephrine. For airway or cutaneous reactions, use 0.3 to 0.5 ml of 1:1000 dilution given subcutaneously every 10 to 20 minutes as needed. Hypotension can be treated with 1 ml of 1:1000 dilution in 50 ml of crystalloid solution at a rate of 0.25 to 2.5 ml/min (0.5 to 5 μg/min).
2. Intravenous fluids. Hypotension may require 1 L of crystalloid solution every 20 to 30 minutes.
3. Oxygen. Give 40% to 100% to maintain an arterial partial pressure of oxygen of ≥60 mm Hg.

Recognition of an anaphylactic reaction is critical. Both the patient and health care worker are at risk for latex allergic reactions. Many commonly used products contain latex, including surgical gloves, catheters, enema devices, stoma bags, condoms, balloons, and rubber bands. For example, persons with spina bifida frequently are exposed to latex because of the need for long-term catheterization, and they are at increased risk for latex anaphylaxis. A history of allergic symptoms that develop when a toy balloon is inflated may help identify a latex allergy. Skin testing is a sensitive method to confirm latex hypersensitivity. The use of nonlatex surgical gloves or glove liners is a simple and effective method to prevent allergic episodes.

In summary, the prompt recognition and therapy of latex allergy are essential for the well-being of both patients and health care workers. Latex anaphylaxis should be included in the differential diagnosis of urticaria, bronchospasm, and hypotension.

Does amniotic fluid analysis reflect acid-base balance in fetal blood?

D.L. Economides, MD, P. Johnson, MA, and I.Z. MacKenzie, MD
Oxford, England

OBJECTIVE: The purpose of the study was to examine whether the acid-base balance in amniotic fluid reflects the acid-base state in fetal blood.
STUDY DESIGN: The pH, Pco_2, Po_2, bicarbonate, and base excess concentrations were measured in umbilical venous, umbilical arterial, and maternal venous blood and in amniotic fluid samples obtained at fetoscopy. This was performed before intraamniotic termination of 16 normal pregnancies (mean gestation 19.4 weeks), as well as in 14 red blood cell isoimmunized pregnancies (mean gestation 28.4 weeks) undergoing fetoscopy for the diagnosis and treatment of fetal anemia.
RESULTS: In normal pregnancies, amniotic fluid pH and bicarbonate were significantly lower than umbilical venous and umbilical arterial blood concentrations, and this was due to the high concentration of base deficit in amniotic fluid. Whereas amniotic fluid Pco_2 did correlate significantly with fetal umbilical venous Pco_2 values, there was no correlation between other acid-base characteristics.
CONCLUSION: Simultaneous sampling of human fetal umbilical blood and amniotic fluid under the acute conditions of this study did not show significant correlations in acid-base values. (AM J OBSTET GYNECOL 1992;166:970-3.)

Key words: Acid-base balance, amniotic fluid, fetal blood, fetoscopy, red blood cell isoimmunization

Fetal blood sampling was originally introduced for the prenatal diagnosis of inherited disorders, but most recently it has been used for assessing fetal well-being.[1, 2] Measurement of blood gases and acid-base status by umbilical cord sampling is the only direct method of diagnosing asphyxia in utero. However, ultrasonographically guided fetal blood sampling requires considerable expertise, is not widely available and can also be difficult in the presence of oligohydramnios. In addition, with cordocentesis either the umbilical vein or artery can be sampled, so physiologic observations regarding placental transfer of oxygen and nutrients to the fetus can be limited. The aim of the current study was to assess whether examination of amniotic fluid, which is more easily obtained than fetal blood, represents acid-base balance and oxygenation of the fetus. To achieve this, amniotic fluid and paired umbilical arterial and umbilical venous blood samples obtained at fetoscopy from midtrimester pregnancies were examined.

Patients and methods

Fetoscopy and fetal blood sampling were preformed in 16 pregnancies before the instillation of prostaglandins for elective abortion at 16 to 24 weeks' gestation. The patients (mean gestation 19.7 weeks) were undergoing termination for social reasons under clause two of the Abortion Act 1967. Fetoscopy was also performed on 14 red blood cell–isoimmunized pregnancies at 18 to 36 weeks' gestation (mean gestation 28.4 weeks) for the diagnosis and treatment of fetal anemia. None of the fetuses was hydropic. Informed consent was obtained from all patients before fetoscopy. Ethics committee support for the principle of fetal blood sampling at the time of termination had previously been obtained. The fetuses were subsequently confirmed at postabortion autopsy to be structurally and chromosomally normal.

Fetoscopy was performed as previously described.[3] Amniotic fluid (10 ml) and fetal blood (1 to 2 ml) from the umbilical vein or artery were obtained under direct vision. In 10 termination cases samples from both the umbilical artery and vein were obtained. Maternal venous blood (10 ml) was also collected from an antecubital vein distal to a tourniquet at the time of fetoscopy.

All samples were collected into preheparinized plastic syringes, and with the Radiometer ABL automatic analyzer (Radiometer, Copenhagen), analyses were performed within 30 minutes of collection. The pH, Pco_2, and Po_2 were measured, and bicarbonate and base deficit were extrapolated. All cord samples were confirmed to be fetal in origin by Kleihauer-Betke testing.

Results were analyzed with the Statistical Package for Personal Computers (P. Royston, London). Regression

analysis was used to test for any correlations between maternal, fetal, and amniotic fluid samples. The paired Student t test was used to test for any differences between amniotic fluid and blood values. Normal and red blood cell–isoimmunized values were compared with the Mann-Whitney test.

Results

The pH, P_{CO_2}, P_{O_2}, base deficit, and bicarbonate concentrations in amniotic fluid, umbilical arterial and venous, and maternal venous blood samples in normal and red blood cell–isoimmunized human pregnancies are summarized in Table I.

In normal pregnancies the amniotic fluid pH was significantly lower than both the umbilical venous pH ($t = 17.4$, $p < 0.0001$) and the umbilical arterial pH ($t = 10.3$, $p < 0.0001$), and the umbilical arterial pH was significantly lower than the umbilical venous pH ($t = 9.75$, $p < 0.0001$). In addition, the amniotic fluid base deficit was significantly higher than both the umbilical venous base deficit ($t = 12$, $p < 0.0001$) and the umbilical arterial base deficit ($t = 7.81$, $p < 0.0001$). The amniotic fluid bicarbonate concentration was significantly lower than the umbilical venous bicarbonate ($t = 11.87$, $p < 0.0001$), umbilical arterial bicarbonate ($t = 7.91$, $p < 0.0001$), and maternal venous bicarbonate ($t = 14.7$, $p < 0.0001$).

Carbon dioxide tension was significantly higher in amniotic fluid than in umbilical venous blood ($t = 9.18$, $p < 0.001$) but not significantly different from umbilical arterial P_{CO_2}. However, the umbilical arterial P_{CO_2} was significantly higher than both the umbilical venous P_{CO_2} ($t = 6.14$, $p < 0.001$) and the maternal venous P_{CO_2} ($t = 2.39$, $p < 0.05$). The mean arteriovenous P_{CO_2} difference was 9.9 mm Hg in paired umbilical samples. The amniotic fluid P_{O_2} was significantly higher than both umbilical venous P_{O_2} ($t = 6.72$, $p < 0.0001$) and umbilical arterial P_{O_2} ($t = 9.83$, $p < 0.0001$). The umbilical venous P_{O_2} was significantly higher than the umbilical arterial P_{O_2} ($t = 13.2$, $p < 0.0001$), and the mean arteriovenous P_{O_2} difference in paired samples was 23.4 mm Hg.

The correlations between amniotic fluid, umbilical venous and arterial, and maternal venous pH, P_{CO_2}, P_{O_2}, base deficit, and bicarbonate in normal and isoimmunized pregnancies at midgestation are shown in Table II. There were significant correlations between amniotic fluid and umbilical venous P_{CO_2} ($r = 0.64$, $p < 0.001$), amniotic fluid and maternal venous bicarbonate ($r = 0.65$, $p < 0.001$), and amniotic fluid and umbilical arterial bicarbonate ($r = 0.45$, $p < 0.05$).

The isoimmunized pregnancies (Table I) had significantly lower amniotic fluid pH ($p < 0.01$) and lower umbilical venous pH ($p < 0.05$) but significantly higher amniotic fluid P_{CO_2} ($p < 0.01$).

Comment

The gas and pH measurements in fetal blood samples obtained at fetoscopy from normal midtrimester human fetuses have been reported previously.[4] The results are in general agreement with those of Soothill et al.,[5] who also reported on fetoscopically obtained samples in midpregnancy. However, in our study, the umbilical venous pH was higher, the umbilical arterial pH was lower, and both umbilical venous and umbilical arterial P_{O_2} were lower. The same authors found that samples obtained fetoscopically were more acidotic and hypercapnic than those obtained at cordocentesis.[6] This was attributed to maternal fasting and sedation, although the maternal arterial blood gases measured at the time of fetoscopy were not abnormal.

Ultrasonographically guided needling of the umbilical cord is now the method of choice for fetal blood sampling, but the advantage of fetoscopy is that paired

‡$p < 0.001$.

umbilical arterial and venous samples may aid our understanding of fetal physiologic characteristics. Thus the umbilical arteriovenous oxygen difference in paired samples in the midtrimester human fetus is 23 mm Hg. Assuming that the mean umbilical venous blood flow at 20 weeks' gestation is 0.15 L/kg/min,[7] then fetal oxygen consumption in midpregnancy can be estimated to be 0.59 mmol/kg/min. This is higher than that measured for the horse (0.31 mmol/kg/min), rhesus monkey (0.31 mmol/kg/min), or guinea pig (0.40 mmol/kg/min).[8]

There were significant correlations between maternal venous pH and umbilical venous or umbilical arterial pH. Similarly, the maternal venous bicarbonate concentration was correlated with both the umbilical blood and amniotic fluid bicarbonate concentrations. Therefore in interpreting the fetal acid-base status one must first confirm a normal acid-base balance in the mother.

The mean pH of amniotic fluid in midtrimester (7.18) is similar to that reported previously,[9,10] although higher than that reported by Rooth et al. (7.12).[11] Amniotic fluid was acidotic and had a high base deficit. This is because of the high concentration of organic acids, especially lactic acid, and also because of its low buffering capacity compared with that of fetal blood.[12] The implication of low amniotic fluid pH is that contamination of fetal blood samples with amniotic fluid, especially in cases of oligohydramnios and intrauterine growth retardation, when cordocentesis might be difficult, could give misleadingly low blood pH values, although this has not been tested in vitro. Not only is amniotic fluid acidotic compared with fetal blood but, in addition, there was no significant correlation between amniotic fluid and umbilical blood pH.

The amniotic fluid P_{CO_2} values are similar to those reported by other investigators.[10] The partial pressure of carbon dioxide in amniotic fluid was not different from that in the umbilical artery. In addition, there was a significant correlation between amniotic fluid and umbilical venous P_{CO_2} and amniotic fluid and maternal venous P_{CO_2}. This is not surprising because carbon dioxide has the ability to diffuse rapidly between fluid compartments.

The amniotic fluid P_{O_2} (mean 86.3 mm) is much higher than that reported in other studies, but there is great variability in the values reported by all the authors who studied this subject (means 2.8 to 99 mm Hg in different studies).[13] However, there are well-known difficulties in measuring P_{O_2} in amniotic fluid, and results are reliable only if the samples are drawn into glass

syringes and stored near the freezing point.[9] In addition, the oxygen content of amniotic fluid is insignificant compared with that of fetal blood because oxygen in amniotic fluid is soluble and not bound to a carrier protein such as hemoglobin. For these reasons, P_{O_2} of amniotic fluid would not be helpful in assessing fetal blood oxygenation.

The isoimmunized pregnancies were more advanced in gestation (mean gestation 28 weeks), so caution must be used when the results are compared with those of the normal pregnancies (mean gestation 19.4 weeks). The amniotic fluid pH was lower and the P_{CO_2} was higher in isoimmunized than in normal pregnancies. However, there was also a comparable decrease in umbilical venous pH, and, because umbilical venous pH and arterial pH decrease and P_{CO_2} increases with gestation in normal fetuses,[14] the pH and P_{CO_2} differences in the two groups might be explained by the effects of gestation. Indeed, 6 weeks before term the pH of amniotic fluid from normal pregnancies is 7.10 and the mean P_{CO_2} 53 mm Hg,[15] indicating that there is a progressive increase in amniotic fluid P_{CO_2} and a concomitant decrease in amniotic fluid pH with gestation. Alternatively, fetal anemia, if severe, could lead to fetal acidosis as a result of lactic acid accumulation.[16]

Simultaneous sampling of normal human fetal umbilical blood and amniotic fluid under the acute conditions of this study did not show significant correlations in acid-base values. It is possible that the time course for change in the amniotic fluid might be so slow that changes in blood values are not immediately observed in the amniotic fluid pool. Whether amniotic fluid acid-base balance would be helpful in the assessment of the chronically acidotic fetus remains to be seen.

Appendix

Calculation of fetal oxygen consumption

Formula 1:

$$\text{Fractional saturation} = \frac{K \times {Po_2}^{2.8}}{1 + K \times {Po_2}^{2.8}}$$

where

$$K = \frac{1}{{P_{50}}^{2.8}}$$

and

$$P_{50} = 21 \times 10^{[-0.48 \times (7.4 - pH)]}$$

Formula 2:

$$\text{Oxygen content} = \text{Hemoglobin (gm/dl)} \times \text{Fractional saturation} \times 0.5982$$

The umbilical arteriovenous oxygen difference was found to be 23.4 mm Hg. Assuming that the hemoglobin concentration at 20 weeks' gestation is 11.7 gm/dl,[17] then the amount of umbilical oxygen uptake can be calculated to be 3.94 mmol/L. Assuming that the umbilical venous blood flow is 0.15 L/kg/min, then the fetal oxygen consumption at 20 weeks' gestation can be estimated to be $3.94 \times 0.15 = 0.59$ mmol/kg/min.

The clinical significance of thrombocytosis in women presenting with a pelvic mass

Eva Chalas, MD,[a] Marie Welshinger, MD,[a] William Engellener, MD,[b] John Chumas, MD,[b] Robert Barbieri, MD,[a] and William J. Mann, MD[a]

Stony Brook, New York

OBJECTIVES: We attempted to determine the clinical usefulness of a preoperative platelet count for predicting malignancy in patients presenting with a pelvic mass. Additionally, in patients in whom a preoperative serum CA 125 level was also determined, the clinical usefulness was compared.
STUDY DESIGN: A retrospective review of charts of 241 patients presenting with a pelvic mass was carried out. The patients were then divided by pathologic diagnosis into group 1, benign disease (n = 102), and group 2, invasive (n = 121) or borderline (n = 18) malignancies. Thrombocytosis (platelet count >400,000/μl) was present in 16% (n = 16) of patients in group 1 and in 56% (n = 78) of patients in group 2 ($p < 0.0001$). Of the 241 patients, 130 also had preoperative serum CA 125 levels measured. Elevated values of serum CA 125 (>35 U/ml) occurred in 14% (n = 8) of group 1 and in 81% (n = 60) of group 2 ($p < 0.0001$). The χ^2 test was used to analyze results of data.
RESULTS: Statistically significant differences in preoperative platelet count and serum CA 125 values were found between group 1 and group 2 patients. The specificity and positive predictive value for thrombocytosis (84% and 83%) compared well with those for serum CA 125 (86% and 88%). The combined use of the tests resulted in specificity of 96% and positive predictive value of 95%.
CONCLUSIONS: Preoperative platelet count is a test that is rapidly available and easily obtained. The test results may be of value in planning the original management of women presenting with a pelvic mass. (Am J Obstet Gynecol 1992;166:974-7.)

Key words: Thrombocytosis, pelvic mass, CA 125

In evaluating and managing a woman with a pelvic mass, serious consideration must be given to the risk of ultimately finding a malignancy. Clinical presentation, patient age, and physical findings may suggest the etiology but can be misleading. Similarly, radiologic evaluation is most accurate with patients having advanced cancer with extraperitoneal or massive intraperitoneal disease, which clinical examination often accurately detects. The patients with early disease or minimal intraperitoneal disease pose the greatest challenge.

The choice of incision, extent of surgery, risk of intraoperative or postoperative complication, and potential need for referral to a tertiary care center are all related to the diagnosis of cancer. Attempts at selecting patients likely to have cancer by relying on serum CA 125 levels are suboptimal because of a significant false-negative rate with early disease and a false-positive elevation related to endometriosis, pelvic inflammatory disease, and other diseases.[1, 2]

One of the authors (W.M.) observed the frequent finding of thrombocytosis in patients presenting with a pelvic mass who were subsequently found to have cancer at exploration. A review of our 10 years' experience suggests that thrombocytosis, if associated with an elevated serum CA 125 level, may improve the preoperative diagnosis of ovarian cancer and assist in management decisions and patient counseling.

Material and methods

Records of 288 patients, seen by the Gynecologic Oncology Service at the State University of New York at Stony Brook, from May 1980 to April 1990 with a pelvic mass were reviewed. Forty-seven patients were excluded from our study for the following reasons: (1) lack of preoperative platelet count and (2) the presence of underlying conditions associated with thrombocytosis (i.e., asplenism, collagen vascular disease, postoperative and postpartum states). No patients had a history of administration of drugs known to cause thrombocytosis. We defined thrombocytosis as a platelet count >400,000/μl, in agreement with other studies.[3-5] Serum CA 125 values >35U/ml were considered abnormal.[1]

All patients underwent exploratory laparotomy, and the surgical specimens were reviewed by a gynecologic oncologist and a gynecologic pathologist. Final pathologic results were used to assign patients to one of two groups: group 1, benign disease (N = 102), and group 2, invasive (n = 121) and borderline ovarian (n = 18) malignancies. The clinical usefulness of elevated platelet count and serum CA 125 levels was assessed by calculating sensitivity, specificity, and positive and negative predictive values, and the null hypothesis was tested with χ^2 analysis.

Results

The pathologic diagnoses of the masses in patients are summarized in Table I and II. The majority of benign masses were adnexal in origin, whereas most patients in group 2 had epithelial ovarian adenocarcinomas. Thrombocytosis was noted in 16 (16%) of the patients in group 1 (Table III) and in 78 (56%) of the patients in group 2 (Table IV). The difference in incidence of thrombocytosis was found to be highly statistically significant ($p < 0.0001$). Table IV also lists the incidence of thrombocytosis in patients with epithelial ovarian malignancy (n = 126) by stage (International Federation of Gynecology and Obstetrics, 1988).

Table III. Diagnoses in patients with abnormal values, group 1

	Thrombocytosis	*Elevated CA 125**
Benign adnexal masses		
Tuboovarian abscess	4 (100%)	1 (50%)
Functional cysts (one torted)	3 (13.6%)	2 (12.5%)
Serous cystadenoma or adenofibroma (one torted)	3 (21.4%)	2 (20%)
Mucinous cystadenoma or adenofibroma	1 (11.1%)	1 (14.3%)
Endometrioma	1 (10%)	2 (50%)
Uterine masses		
Leiomyoma (one atypical and one torted)	4 (18.1%)	0 (0%)
TOTAL	16	8

*Serum CA 125 values were not obtained from all patients.

Table IV. Diagnoses in patients with abnormal values, group 2

	Thrombocytosis	*Elevated CA 125**
Epithelial ovarian malignancies		
Stage I	11 (44%)	8 (53%)
Stage II	2 (50%)	2 (67%)
Stage III	39 (61%)	31 (97%)
Stage IV	22 (69%)	15 (94%)
Immature teratoma	1 (100%)	1 (100%)
Sertoli-Leydig cell	0 (0%)	1 (50%)
Mesothelioma	1 (100%)	1 (100%)
Primary peritoneal carcinoma	1 (100%)	1 (100%)
Ovarian sarcoma	1 (100%)	—
TOTAL	78	60

*CA 125 values were not obtained from all patients.

Preoperative serum CA 125 values were not available in all patients. However, elevated levels were noted in 8 of 56 (14%) patients in group 1 and in 60 of 74 (81%) in group 2 (Tables III through V); the difference was again highly significant ($p < 0.0001$).

Table VI lists the sensitivity, specificity, and positive and negative predictive values of thrombocytosis, serum CA 125 levels, and both tests in patients presenting with pelvic masses. Additionally, patients in groups 1 and 2 were subdivided by age (Table VII). When compared with younger patients, patients >50 years old with thrombocytosis had a higher positive predictive value and sensitivity and specificity, but the negative predictive value for the test was decreased. Throm-

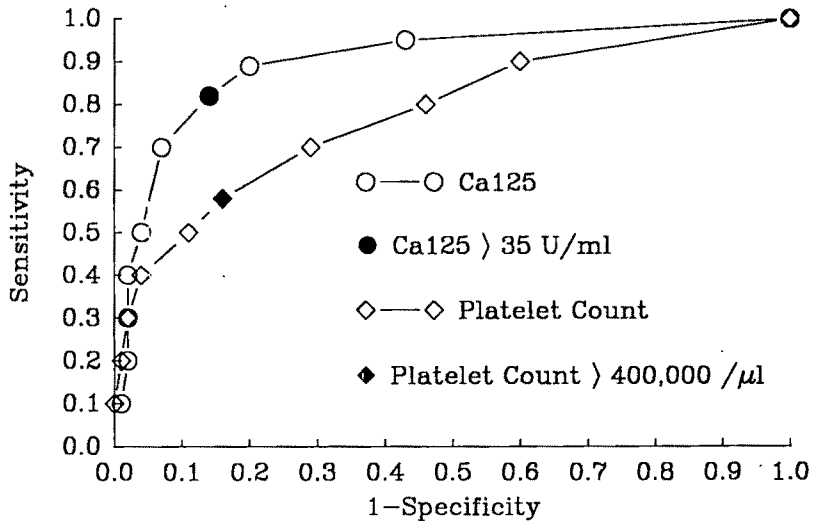

Fig. 1. Receiver-operator characteristic curve for platelet count and CA 125.

Table V. Incidence of thrombocytosis, elevated serum CA 125 levels and both values in groups 1 and 2

Population	*Thrombocytosis*	*CA 125*	*Both*

Positive predictive value	83	88	95
Negative predictive value	59	77	39

bocytosis was not seen after operation or during chemotherapy. Patients with recurrent disease did not have thrombocytosis. Fig. 1 depicts the receiver-operator characteristic curves for platelet counts and serum CA 125 values. Although serum CA 125 level is a superior test, platelet count >400,000/μl appears to represent a clinically useful marker.

Comment

Ginsburg[4] defined thrombocytosis as a moderately short-lived and symptomless elevation of platelet count occurring in association with certain underlying diseases. A specific stimulus for thrombocytosis has not been identified. Proposed theories include tumor-related humoral factors with thrombopoietin-like activity[6] and a tumor-stimulated state of overcompensated disseminated intravascular coagulopathy.[7-9] Thrombocytosis has been shown to be associated with underlying malignancy in a number of studies.[6-11] When those with myeloproliferative disorders were excluded, 36% of patients with thrombocytosis were diagnosed as having a malignant neoplasm. Patients with ovarian cancer accounted for 20% of this population.[10] Other conditions (i.e., anemia, inflammatory bowel disease, trauma, etc.) can stimulate platelet production,[7] resulting in a lack of suitability of the test for screening purposes.

Table VII. Statistical parameters for thrombocytosis, CA 125 levels, and the combined tests by age

	Age (yr)	*Thrombocytosis (%)*	*CA 125 (%)*	*Both (%)*
Sensitivity	<50	50	74	44
	≥50	60	85	53
Specificity	<50	83	83	97
	≥50	87	88	96
Positive predictive value	<50	68	80	92
	≥50	92	93	96
Negative predictive value	<50	70	78	66
	≥50	47	77	53

The majority of patients with ovarian carcinoma are first seen with advanced disease.[12] Currently, there are many tumor markers that have been evaluated in patients with ovarian carcinoma.[13-18] Monitoring serum CA 125 levels has become standard in these patients, but a sensitive screening tool to detect or predict the presence of ovarian carcinoma is not yet available. Recently, the use of vaginal ultrasonography with serum CA 125 values has shown some promise.[19-21] We have

demonstrated that thrombocytosis found in patients presenting with a pelvic mass is a highly significant finding, with up to 50% of patients with stage I and stage II ovarian malignancies having thrombocytosis. Although thrombocytosis was found in 16% (n = 16) of patients in group 1, seven of these patients had pathologic conditions that could result in stimulation of platelet production (four with inflammatory process, two with adnexal torsion, and one with infarcted leiomyoma), and an additional five patients were found to have a benign neoplasm (four with cystadenomas and one endometrioma).

The specificity and positive predictive values for thrombocytosis compared quite well with those of preoperative serum CA 125 values obtained in patients in our study, but the sensitivity of the test is poor. In addition, a comparison of the statistical parameters of thrombocytosis with previously published values for serum CA 125 in predicting the presence of malignancy in patients with a pelvic mass was favorable.[1, 12, 22-25] In patients >50 years old, when the incidence of most gynecologic malignancies increases, the positive predictive value of thrombocytosis was obviously improved. Finally, in the subgroup of patients where a preoperative CA 125 value was also available, the use of combined tests resulted in a very high specificity (96%) and positive predictive value (95%).

Gynecologists are frequently presented with the difficulty of counseling a patient with a pelvic mass. Preoperatively, they must prepare the patient for the possibility of a malignancy and assess whether such a patient would benefit by referral to a specialist. Platelet count is easily performed and the result is rapidly available. Frequently, the test is obtained routinely as part of a complete blood cell count, but the results may go unnoticed or are not found to be clinically important. The combined use of platelet count and serum CA 125 values results in a very high specificity and positive predictive value.

Unexplained elevated maternal serum α-fetoprotein is not predictive of adverse perinatal outcome in an indigent urban population

Owen P. Phillips, MD,[a] Joe Leigh Simpson, MD,[a] Cynthia D. Morgan, RNC, MS,[a] Richard N. Andersen, PhD,[a] Lee P. Shulman, MD,[a] Carole M. Meyers, MD,[a] Baha Sibai, MD,[a] David C. Shaver, MD,[a] Elizabeth A. Tolley, PhD,[b] and Sherman Elias, MD[a]

Memphis, Tennessee

OBJECTIVE: The null hypothesis of this study is that in an urban, indigent obstetric population at high risk for adverse perinatal outcome, unexplained elevations of maternal serum α-fetoprotein are not an additional predictor of adverse perinatal outcome.

STUDY DESIGN: Perinatal outcomes of 72 patients from a clinic for indigent patients with unexplained elevated maternal serum α-fetoprotein levels were compared with those of matched controls from the same population with normal maternal serum α-fetoprotein levels. Subjects and controls were matched for age, race, parity, and presence or absence of Hollister risk factors. The frequency of adverse perinatal outcome in the two groups was subjected to matched-pair χ^2 analysis.

RESULTS: Adverse perinatal outcome occurred in 38.9% (28 of 72) of subjects with unexplained elevated maternal serum α-fetoprotein levels ≥2.5 multiples of the median, compared with 31.9% (23 of 72) of controls with normal maternal serum α-fetoprotein levels ($p = 0.5$). No statistically significant difference in adverse perinatal outcomes was found.

CONCLUSIONS: Elevated maternal serum α-fetoprotein levels offer little if any additional predictive value for adverse perinatal outcome in populations already at high risk for such outcomes on the basis of obstetric or socioeconomic criteria. (AM J OBSTET GYNECOL 1992;166:978-82.)

Key words: Maternal serum α-fetoprotein, adverse perinatal outcome

Several studies have shown an association between adverse perinatal outcome and unexplained elevated levels of maternal serum α-fetoprotein (AFP).[1-5] Such adverse perinatal outcomes included fetal loss, preterm labor, preterm rupture of membranes, pregnancy-induced hypertension, stillbirth, intrauterine growth retardation (IUGR), and abruptio placentae.[1-5] Investigators logically have recommended that patients with unexplained elevated maternal serum AFP should be considered high risk for adverse perinatal outcome and should have very close, but as yet undefined, prenatal follow-up.[4-7]

These studies, however, were all conducted in obstetric populations that were predominantly low risk. For example, the study population of Milunsky et al.[6] was mostly white (94%) and received prenatal care from private obstetricians. The study populations of Burton[4] in North Carolina and Robinson et al.[5] in California were derived from regional neural tube defect screening programs that included private practice patients. Studies of Wald et al.,[1] Brock et al.,[2] and Smith[3] were from Great Britain, with demographic information not offered. In addition, matched-pair analysis was not performed in any of these studies.

The purpose of this study was to determine whether unexplained elevated maternal serum AFP would show additional predictive value in patients already identified to be high risk for adverse perinatal outcome on the basis of other obstetric or socioeconomic criteria.

Material and methods

Subjects and controls, to be defined below, received obstetric care between Jan. 1, 1987, and Dec. 31, 1989, at the Regional Medical Center, Memphis, Tennessee. In 1990 this population was 79.6% black, 89% indigent (78% on Medicaid, 11% uninsured), and 61% unwed, with an estimated 10% incidence of maternal substance abuse. All patients were offered maternal serum AFP screening between 15 and 20 weeks.

Maternal serum AFP assays were performed with the Abbott enzyme immunoassay. An elevated maternal serum AFP level was defined as ≥2.5 multiples of the

Table I. Unequivocal risk factors for adverse perinatal outcome*

Cardiac disease (class I to IV)	Smoking (>1 pack per day)
Tuberculosis, active	Prior fetal or neonatal death
Chronic pulmonary disease	Diabetes mellitus
Thrombophlebitis	Hypertension
Endocrinopathy	Chronic renal disease
Epilepsy (on medication)	Congenital-chromosomal anomalies
Two abortions (spontaneous)	Hemoglobinopathies
Previous preterm or small-for-gestational-age infants	Isoimmunization (Rh)
Isoimmunization (ABO, etc.)	Alcohol or drug abuse
Incompetent cervix	Habitual abortions
Previous preeclampsia	

*Adapted from Preexisting Risk Guide, Hollister Inc., Libertyville, Ill.

Table II. Risk factors that do not unequivocally place a patient at risk for adverse perinatal outcome*

Age <15 or >35 yr	<8th Grade education
≥7 Deliveries	Infants ≥4000 gm
Hemorrhage during previous pregnancy	Surgically scarred uterus
Pregnancy without familial support	Second pregnancy in 12 mo
Age ≥40 yr	Prior neurologically damaged infant
Significant social problems	Infertility

*Adapted from Preexisting Risk Guide, Hollister Inc., Libertyville, Ill.

median, adjusted for weight, race, and diabetes mellitus. If maternal serum AFP was 2.5 to 2.9 multiples of the median and the patient's estimated gestational age was ≤18 weeks, our policy was to repeat the assay 1 week later. If the repeat value was <2.5 multiples of the median, maternal serum AFP was considered normal and the patient was not included in the study. If a repeat sample was ≥2.5 multiples of the median, if the initial value was ≥3.0 multiples of the median, or if gestational age was ≥18 weeks, high-resolution ultrasonographic examination was performed. The 18-week cutoff was chosen to ensure that patients potentially carrying an anomalous fetus later in the second trimester would be evaluated in time that all pregnancy options could be offered, including termination. If gestational age that was based on ultrasonographic measurements differed from gestational age that was based on onset of last menses by >14 days, maternal serum AFP was reinterpreted with ultrasonographic dating; values reinterpreted as being within the normal range were considered explained. Amniocentesis was offered to patients having no ultrasonographic explanation for elevated maternal serum AFP levels. Patients who declined amniocentesis were included in our analysis; patients who declined ultrasonography or were found to have multiple gestations were excluded.

An elevated maternal serum AFP value was considered unexplained if, after correcting for erroneous gestational age, multiple gestation, and fetal death, no abnormality in fetal anatomy was detected on ultrasonographic examination. Patients who had oligohydramnios (<2 cm pocket of amniotic fluid on ultrasonography) were excluded because of the known association between oligohydramnios, unexplained elevated maternal serum AFP, and poor outcome.[8]

Standard Hollister forms (Hollister Inc., Libertyville, Ill.) were completed by perinatal nurses or house staff at the initial visit on all patients. This form permits information to be recorded concerning the patient's past medical history, family history, previous pregnancy outcomes, and presence or absence of 33 factors that help identify pregnancies at risk for adverse outcome. In our opinion 21 of the 33 risk factors unequivocally place a patient at increased risk for adverse outcome (Table I); however, the other 12 factors are social factors or other factors that do not, in our opinion, unequivocally place a patient at increased risk (Table II). Subjects of this study were thus subgrouped according to presence or absence of any of the 21 unequivocal medical risk factors (Table I).

According to a table of random numbers, controls were selected from patients who had singleton pregnancies and normal maternal serum AFP levels (<2.5 multiples of the median and with a Down syndrome risk less than that of a 35-year-old woman at midtrimester, i.e., 1 in 277). Subjects were matched for the presence or absence of any of 21 medical risk factors (i.e., risk factors present or not present), race (white vs black), age (5-year intervals), and parity (0 vs ≥1).

Pregnancy outcome data were gathered from hospital records by a single physician who was unaware of maternal serum AFP status at the time of review. Outcome variables specifically assessed were congenital malformations, spontaneous pregnancy loss <20 weeks, preterm labor (<37 weeks), preterm rupture of membranes (<37 weeks), IUGR, stillbirths, pregnancy-induced hypertension, and abruptio placentae. Statistical analysis was done by McNemar's test (matched-pair χ^2 test),[9] a test that minimizes the effects of confounding variables.

Results

Among 6208 patients undergoing maternal serum AFP screening during the study period, 88 (1.4%) had unexplained elevated values; three of the 88 were excluded because multiple gestation, four because of oligohydramnios, and nine because outcomes could not

be obtained. The mean age of the remaining 72 patients was 24.9 years (range 15 to 37 years). Sixty-four (89%) of subjects were black; eight (11%) were white. Forty-six (64%) were multiparous. Unequivocal risk factors (Table I) were documented in 36 (50%) of the 72 subjects with unexplained elevated maternal serum AFP levels. The mean of the multiples of the median values in the control group was 1.16 ± 0.48 (SEM), indicating that the control group's maternal serum AFP values were not skewed high or low.

Pregnancy outcome data are summarized in Table III. Adverse perinatal outcome occurred in 38.9% (28 of 72) of subjects with unexplained elevated levels ≥2.5 multiples of the median, compared with 31.9% (23 of 72) of controls with normal levels (p = 0.5). Further, no statistically significant difference was found when subjects and controls were compared for any specific outcome (Table III). No stillbirths occurred in either the subject or control group.

To determine whether identifying Hollister risk factors helped predict perinatal outcome in patients with unexplained elevated maternal serum AFP levels, subjects with unexplained elevated levels and risk factors were compared with matched controls having normal levels and risk factors (Table IV). No statistically significant difference in adverse outcomes was observed. Similarly, comparing patients with unexplained elevated levels but no risk factors with matched controls with both normal levels and no risk factors again yielded no statistically significant difference with respect to adverse perinatal outcome (Table IV).

Additional analysis was performed comparing those subjects with maternal serum AFP value ≥3.0 multiples of the median with matched controls (Table V). Thirty-three subjects (45.8%) had values ≥3.0 multiples of the median. Adverse perinatal outcome occurred in 16 (48.5%) of these subjects, compared with 12 (36.4%) controls (p = 0.42). Again, no statistically significant difference for any specific outcome was found when analyzed according to presence or absence of risk factors (Table VI).

Finally, verifying the high-risk nature of our population is the observation that the frequency of adverse outcome in controls with risk factors was similar to that in controls without risk factors (30.6% vs 33.3%, Table IV). This seems to suggest that in our population preexisting risk factors do not identify patients at high risk. However, six of these 36 controls without risk factors were young primigravid women with pregnancy-induced hypertension. In our population pregnancy-in-

duced hypertension is very common, occurring in 19.4% of controls without risk factors in this study. If young primigravid women without risk factors and pregnancy-induced hypertension are excluded from analysis, controls with Hollister risk factors indeed show a trend toward more adverse outcomes (13.2%) than controls without risk factors (7.9%).

Comment

Our matched-pair analysis failed to confirm the observations of others that patients with unexplained elevated maternal serum AFP have an increased risk of adverse perinatal outcome regardless of whether a cutoff of ≥2.5 or ≥3.0 multiples of the median was used. We realize that the number of subjects in this study is relatively small, limiting the power. To achieve a power of 0.80 and a significance level of 0.05, a sample size of 350 subjects would be required to detect a difference of 10.5% in adverse outcomes. However, our findings suggest that the clinical significance of unexplained elevated maternal serum AFP levels in an urban, indigent population having an a priori increased risk for adverse perinatal outcome needs to be reconsidered.

When subjects were subgrouped according to presence or absence of risk factors and compared with controls (matched for the presence or absence of risk factors), no predictive value for elevated maternal serum AFP was found. IUGR occurred in six (16.7%) subjects with unexplained elevated levels and one (1.4%) control; this difference is not statistically significant (p = 0.125). A larger sample size may have demonstrated significance. However, all subjects with IUGR had preexisting factors that placed them at high risk for such an outcome (e.g., significant drug and alcohol use, n = 4; prior neonatal death, n = 2; hypertension, n = 1).

In our subjects with preexisting risk factors, an unexplained elevated maternal serum AFP level did not further define a subpopulation at even higher risk. Furthermore, no difference in adverse perinatal outcome was observed when subjects with unexplained elevated levels and no Hollister risk factors were compared with controls with normal levels and no Hollister risk factors. Irrespective of whether women actually had preexisting Hollister risk factors, maternal serum AFP did not appear to have additional predictive value for adverse perinatal outcome.

In summary, the association between unexplained

maternal serum AFP levels and adverse perinatal outcome may not apply to all obstetric populations. Our study differs from others[1-6] in that it involved an indigent urban population that is already known to be at increased risk for adverse perinatal outcome. Unexplained elevated maternal serum AFP does not appear to have additional predictive value in this population. We therefore suggest further studies from institutions whose populations are similar to ours.

Pelvic inflammatory disease: Trends in hospitalizations and office visits, 1979 through 1988

Robert T. Rolfs, MD, Edward I. Galaid, MD, MPH, and Akbar A. Zaidi, MS
Atlanta, Georgia

OBJECTIVES: We attempted to assess trends in pelvic inflammatory disease occurrence and to describe current antibiotic treatment and use of surgical procedures for pelvic inflammatory disease in the United States.
STUDY DESIGN: Analyses of hospitalizations according to the National Center for Health Statistics, National Hospital Discharge Survey for 1979 to 1988, and of office visits to private physicians from the National Disease and Therapeutic Index for 1979 to 1989 were done.
RESULTS: From 1979 to 1988, a mean of 181,700 women aged 15 to 44 years were hospitalized each year for acute pelvic inflammatory disease (3.03/1000 women) and 94,400 for chronic pelvic inflammatory disease (0.90/1000), and nearly 400,000 first visits for pelvic inflammatory disease were made each year to private physicians' offices (7.2/1000 women). Mean visit and hospitalization rates for acute pelvic inflammatory disease were highest for women aged 20 to 24 years and for other-than-white women. By 1987 to 1988, however, pelvic inflammatory disease hospitalization rates were highest for teenagers. Surgery was performed during 42% of hospitalizations for acute pelvic inflammatory disease and 90% of hospitalizations for chronic pelvic inflammatory disease. Over this time period, hospitalization rates for acute pelvic inflammatory disease decreased by 36% while office visit rates remained unchanged.
CONCLUSION: This decrease in hospitalizations for pelvic inflammatory disease may indicate a true decrease in its incidence, changes in physician hospitalization practices, or a shift in the spectrum of severity of pelvic inflammatory disease. (Am J Obstet Gynecol 1992;166:983-90.)

Key words: Pelvic inflammatory disease, salpingitis, epidemiology, surveillance

Pelvic inflammatory disease is a common serious complication of sexually acquired infection[1-3] and can cause tubal damage leading to infertility, ectopic pregnancy, and chronic pelvic pain.[4, 5] The total economic cost of pelvic inflammatory disease was estimated at $4.2 billion in 1990.[6] Because pelvic inflammatory disease is the most important sequela of cervical infection caused by *Neisseria gonorrhoeae* and *Chlamydia trachomatis*, data on its occurrence are needed both to identify those at risk of sequelae and to evaluate public health initiatives to reduce occurrence of these infections.

Pelvic inflammatory disease is not a reportable condition, however, and data on the actual number of cases occurring in the United States are unavailable. Therefore we analyzed recent trends in hospitalizations and visits to private, office-based physicians for pelvic inflammatory disease in an attempt to understand recent trends in occurrence. Additionally, we examined characteristics of and trends in management of patients with pelvic inflammatory disease, including antibiotic therapy, surgical treatment, and duration of hospitalization.

Material and methods

Data on hospitalizations for pelvic inflammatory disease were obtained from the National Hospital Discharge Survey (NHDS) conducted annually by the National Center for Health Statistics. The NHDS abstracts demographic data, final diagnoses, and procedures performed from a sample of medical records from approximately 400 nonfederal, short-stay hospitals representing all 50 states and the District of Columbia. More than 200,000 medical records are sampled each year and the data are weighted to represent approximately 30 million hospital discharges per year.

Data from the NHDS were analyzed from 1979 through 1988, the period during which the *International Classification of Diseases, ninth revision, Clinical Modification*[7] (ICD-9) was used to code discharge diagnoses. Patient discharges were included as hospitalizations for pelvic inflammatory disease if one of the following ICD-9 codes was listed as one of up to seven final diagnoses: salpingitis and oophoritis (614.0 to 614.2, 098.17, 098.37), parametritis and pelvic peritonitis (614.3 to 614.5, 0.98.86), pelvic inflammatory disease (614.7 to 614.9, 098.10, 098.30, 098.39), and inflammatory disease of the uterus, except cervix

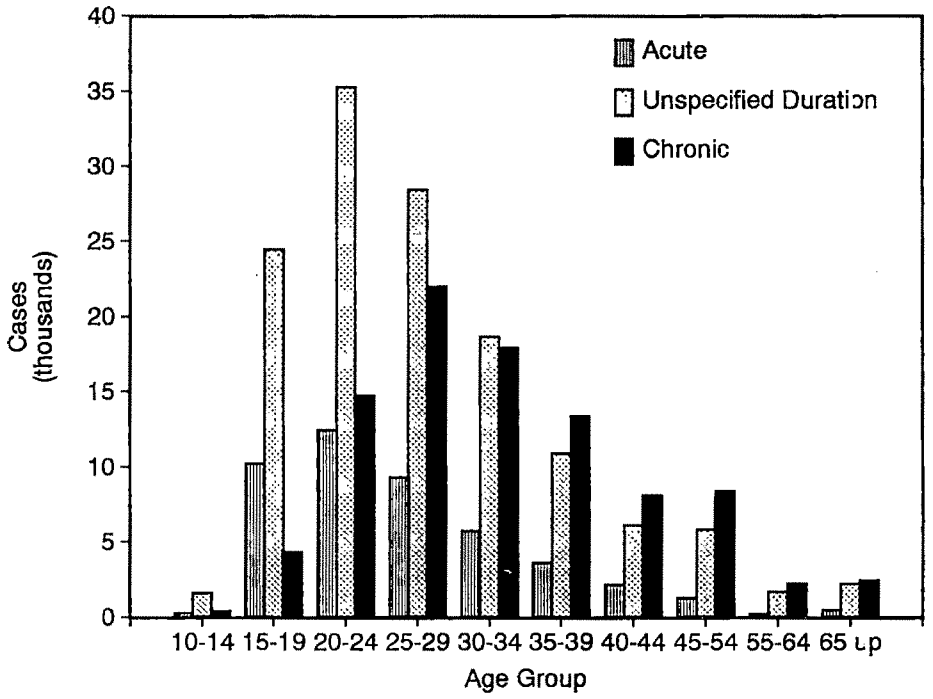

Fig. 1. Average annual number of hospitalizations for pelvic inflammatory disease in United States from 1979 to 1988. Age distribution of cases by disease duration as classified by ICD-9 disease codes (see text).

(615.0, 615.1, 615.9, 098.16, 098.36). These diagnostic classifications specifically exclude complications of abortion or childbirth. Within some diagnostic categories, cases are coded as being of acute, chronic, or unspecified duration; in some categories duration cannot be specified. To assess the significance of the specified duration of pelvic inflammatory disease, hospitalizations were initially classified as acute if at least one acute pelvic inflammatory disease code was listed, as chronic if at least one chronic (but no acute) code was listed, and as unspecified if neither acute nor chronic codes were listed. These results were used to guide subsequent analyses.

The NHDS lists up to four procedures for each hospitalization. We classified surgical procedures that seemed likely to be related to pelvic inflammatory disease and involved the abdominal or pelvic organs as being primarily diagnostic, therapeutic (without organ removal), or for organ removal.

Data on outpatient visits for pelvic inflammatory disease were obtained from the National Disease and Therapeutic Index for the years 1979 to 1989. This index is a commercially conducted (IMS America) survey of patient encounters with physicians in office-based, private practices in the United States. Approximately 2130 physicians are surveyed quarterly to represent >200,000 eligible physicians in 19 primary care specialties. Physicians who are selected report on all patient encounters during one 48-hour period each quarter. National estimates of patient-physician encounters are projected from this sample. Diagnoses were coded with the *International Classification of Diseases, seventh revision*[8] (ICD-7) through 1986 and with ICD-9 from 1987 to 1989. A visit was considered to represent pelvic inflammatory disease if an ICD-9 code indicating either acute or unspecified-duration pelvic inflammatory disease (same as for the National Hospital Discharge Survey) was listed for the years 1987 to 1989 or a corresponding ICD-7 code (salpingitis or oophoritis, 6220, 6230, 6240; pelvic inflammatory disease and parametritis 6262; endometritis, 6301) was listed for the years 1979 to 1986. Chronic pelvic inflammatory disease was rarely reported.

Of the six categories of patient-physician encounters reported in the National Disease and Therapeutic Index (office visits, house calls, hospital visits, phone calls, nursing home visits, and other), only office visits were included in this analysis. Demographic data, antibiotic and other drug therapy provided, and whether the visit was the initial one for that patient and condition are recorded for each visit. For most analyses, data are presented for the 10-year period 1979 to 1988 to be compatible with the hospitalization data and allow the use of 5-year averages.

Annual age, race, marital status, and region-specific hospitalization rates (National Hospital Discharge Survey) and physician visit rates (National Disease and Therapeutic Index) were calculated using Bureau of the Census population estimates.[9-12] Race was categorized as white or other-than-white. Mean case totals for

*Average annual number of cases in years 1979 to 1988.

†Rate per 1000 women and based on average annual cases and average population (except for marital status, which is based on 1984 population estimates).

‡Standard errors of rate estimates, expressed as cases per 1000 women.

§Cases with missing information (14% of cases for marital status, 7% for race) were prorated to distribution of known cases.

‖Estimates for which valid confidence limits could not be calculated. These point estimates should be interpreted with caution.

2- or 5-year time periods were used to improve the precision of some estimates.

χ^2 testing, incorporating a correction factor based on sampling weights and correlations between years, was used to test differences between proportions. Weighted least-squares analysis (using inverse of variance as weights) was used to test time trends . A *t* test was used to test differences between means. Standard error estimates were provided by each survey.

Results

Rates and trends in hospitalizations for pelvic inflammatory disease. Between 1979 and 1988, a mean of 276,100 hospitalizations for pelvic inflammatory disease occurred each year; of these, a mean of 46,100 (17%) were classified as being for acute illness, 94,400 (34%) for chronic illness, and 135,600 (49%) for illness of unspecified duration. Women hospitalized for chronic disease were distinctly older than women hospitalized for acute and unspecified pelvic inflammatory disease (Fig. 1). For hospitalizations where marital status was known (86%), 58% of women hospitalized for chronic pelvic inflammatory disease, compared with 35% for acute and 43% for disease of unspecified duration, were married ($p < 0.01$). Surgery was performed during 90% of hospitalizations for chronic pelvic inflammatory disease, compared with 34% for acute disease and 41% for disease of unspecified duration ($p < 0.01$). The diagnosis of chronic pelvic inflammatory disease thus appeared to represent a distinctly different clinical syndrome occurring in a different subset of women. Therefore for subsequent analyses hospitalizations for acute or unspecified-duration pelvic inflammatory disease were grouped together as acute disease and analyzed separately from those for chronic disease. Women from 15 to 44 years of age accounted for 92% of hospitalizations for acute and 86% of hospitalizations for chronic pelvic inflammatory disease; subsequent analyses were restricted to women in this age group.

The mean annual rate of hospitalization for acute pelvic inflammatory disease was highest for women 15 to 29 years of age (Table I); in contrast, rates for chronic pelvic inflammatory disease were highest for women 25 to 39 years old. Mean annual hospitalization rates were higher for women of other-than-white race than for women of white race for both acute (rate ratio 2.74, 95% confidence interval 2.60 to 2.89) and chronic pelvic inflammatory disease (2.10, 1.97 to 2.23). The mean ages and age distributions did not vary by racial group for acute or chronic pelvic inflammatory disease. For acute disease, rates were higher for women who were

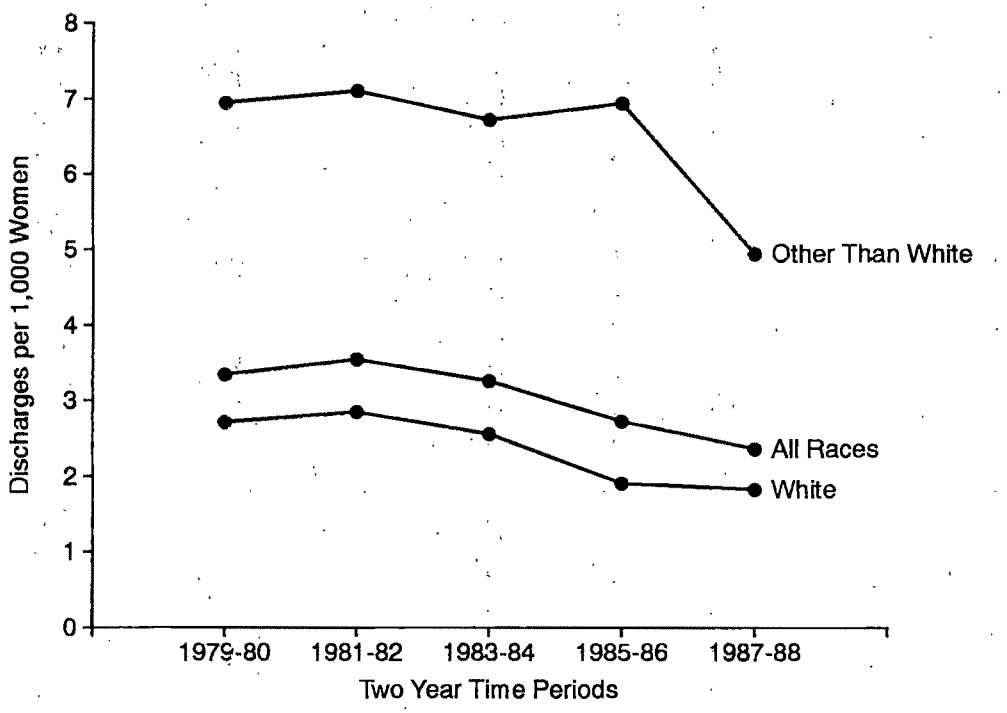

Fig. 2. Trends in hospitalizations for acute pelvic inflammatory disease among white and other-than-white women in United States from 1979 to 1988. Acute pelvic inflammatory disease refers to ICD-9 codes designating acute or unspecified duration disease (see text). Rates are presented as 2-year means.

single, separated, or divorced than for women who were married or widowed ($p < 0.05$). For both acute and chronic pelvic inflammatory disease, rates were highest in the South, lowest in the Northeast, and intermediate in the Midwest and West ($p < 0.05$).

A decrease in the incidence of hospitalization for acute pelvic inflammatory disease in the United States began in about 1983 and continued through 1988 (Fig. 2). Overall, rates decreased 36% from 1979 to 1988, from 3.47 to 2.23 per 1000 women. Over the decade, rates decreased similarly for women of both racial groups; hospitalization for acute pelvic inflammatory disease was 2.7 times more common for women of other races than for white women in 1987 to 1988, essentially the same as in 1979 to 1980 (2.6 times higher).

Hospitalization rates also decreased for all age groups from 15 to 44 years of age (Fig. 3). Rates decreased least for 15 to 19 year olds (10%); as a result, 1987 to 1988 hospitalization rates were highest for this age group. Hospitalization rates for acute pelvic inflammatory disease decreased in all four geographic regions.

During this time period, the hospitalization rate for chronic pelvic inflammatory disease decreased by 40%, from 1.82 in 1979 to 1980 to 1.09 in 1987 to 1988. As with acute pelvic inflammatory disease, rates decreased in all age groups and regions and for both racial groups.

Rates and trends in office visits for pelvic inflammatory disease. Between 1979 and 1988, a mean of 1.2 million visits to private physicians' offices were made each year for acute pelvic inflammatory disease. A mean of 420,000 visits (34%) each year were initial visits for pelvic inflammatory disease. Of these, 95% were by women 15 to 44 years of age, a mean annual rate of 7.2 visits per 1000 women (95% confidence interval 7.15 to 7.25). The rate of initial office visits for acute pelvic inflammatory disease changed little over this time period (Table II).

Most visits for pelvic inflammatory disease were to obstetrician-gynecologists (45%) or general and family practitioners (27%); the remainder were seen by physicians in a variety of specialties. This pattern did not change over the study period.

The age distribution of annual visit rates from the National Disease and Therapeutic Index was similar to the age distribution of hospitalizations for acute pelvic inflammatory disease (Tables I and II). Visit rates for white women were lower than for women of other races, although the rate ratio comparing other-than-white women with white women for initial office visits (1.6, 95% confidence interval 1.1 to 2.1) was substantially lower than the comparable rate ratio for hospitalizations for acute pelvic inflammatory disease. To evaluate change by racial grouping, 4-year means were calculated for the years 1982 to 1985 and 1986 to 1989. Visit rates changed by <0.2 visits per 1000 women per

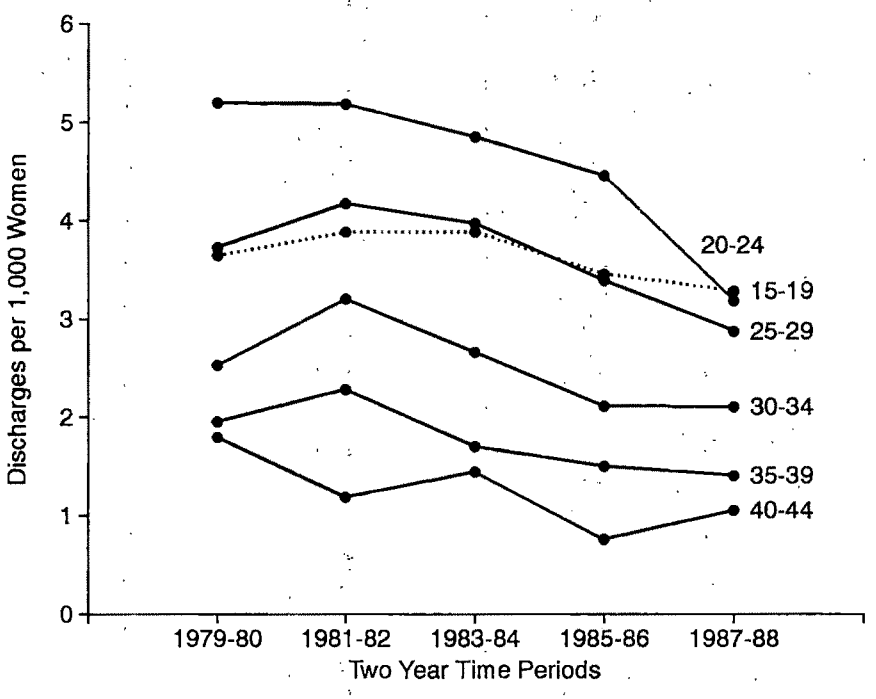

Fig. 3. Trends in hospitalizations for acute pelvic inflammatory disease in United States from 1979 to 1988, by 5-year age groups. Acute pelvic inflammatory disease refers to ICD-9 codes designating acute or unspecified-duration disease (see text). Rates are presented as 2-year means.

year for women of both racial groups between these two time periods (data not shown). As for hospitalizations, pelvic inflammatory disease visit rates were highest in the South.

Surgical and diagnostic procedures for pelvic inflammatory disease. Surgery was performed during 42% of hospitalizations for acute and 90% of hospitalizations for chronic pelvic inflammatory disease ($p < 0.01$). Among patients with acute disease, the proportion undergoing surgery increased steadily with increasing age, from 30% of 15- to 19-year-olds to 66% of 40- to 44-year-olds ($p < 0.01$). Surgery was more common for white women (44%) than for women of other races (37%, $p < 0.01$). The rate of surgery varied little by region for either acute or chronic pelvic inflammatory disease.

Of patients with acute disease undergoing surgery 36% underwent a procedure involving organ removal, 29% a therapeutic procedure not involving organ removal, and 17% a diagnostic procedure only; the other 19% had a surgical procedure that appeared unrelated to pelvic inflammatory disease. Among patients with chronic disease undergoing surgery, 63% underwent an organ removal procedure ($p < 0.01$, comparison of acute and chronic pelvic inflammatory disease). Commonly performed surgical procedures included lysis of peritoneal adhesions, hysterectomy, salpingo-oophorectomy, laparoscopy, and curettage.

Laparoscopy, often considered the gold standard test for diagnosing pelvic inflammatory disease, was performed for 12% of patients with acute and 19% of patients with chronic disease between 1979 and 1988. These proportions changed little over the study period. The most notable change in procedures used to diagnose or treat pelvic inflammatory disease over this time period occurred for pelvic ultrasonography, use of which increased from 2% of hospitalizations for acute pelvic inflammatory disease in 1979 to 19% of hospitalizations in 1988 ($p < 0.01$). Ultrasonography was used more commonly for younger women (14% in the 15- to 19-year age group compared with 3% in the 40- to 44-year age group in 1984 to 1988). Use of pelvic ultrasonography also varied among regions; in 1987 to 1988, it was used for 33% of hospitalizations in the Northeast, 19% in the Midwest and West, and 11% in the South ($p < 0.05$). Ultrasonography was used infrequently for chronic versus acute pelvic inflammatory disease (3% vs 9%, 1979 to 1988, $p < 0.01$).

Hospital stay and payment method for pelvic inflammatory disease. The mean length of hospitalization over the 10-year period was 5.3 days (95% confidence interval 4.1 to 6.5) for acute and 5.9 days (3.9 to 7.9) for chronic pelvic inflammatory disease. The mean hospital stay did not change significantly over the study period. For both acute and chronic disease, length of hospital stay increased with increasing age, from 4.7 days in the 15- to 19-year age group to 7.2 days in the 40- to 44-year age group for acute pelvic inflammatory

*Initial office visits for acute pelvic inflammatory disease. "Acute" refers to ICD-7 and ICD-9 codes for acute or unspecified-duration pelvic inflammatory disease.

†Rate per 1000 women and based on average annual number of visits and average population.

‡Standard error of rate estimate, expressed as cases per 1000 women.

§Estimates for which valid confidence limits could not be calculated. These point estimates should be interpreted with caution.

‖Race data were not available for 1979 to 1981. For 1984 to 1988, cases with missing racial information (1.5%) were prorated to distribution of known cases.

disease ($p < 0.05$ for trend). Hospital stays did not differ among regions or between racial groups.

The cost of both acute and chronic pelvic inflammatory disease hospitalization was most commonly covered by private insurance. For acute disease, 59% of hospitalizations were covered by private insurance, 26% by public payment methods, and 15% by other means (no charge, self-pay, other). Public payment was more common for women of other-than-white race than for white women (36% and 19% for acute pelvic inflammatory disease) and for younger women than for older women (28% for 15- to 19-year-olds and 14% for 40- to 44-year-olds). Payment patterns changed little over the study period.

Antibiotic therapy for pelvic inflammatory disease. Treatment with at least one antimicrobial drug was recorded for 87% of office visits for pelvic inflammatory disease from 1979 to 1989. Of these, at only half (54%) of visits did the woman receive a drug effective against *C. trachomatis* (tetracycline, erythromycin, or clindamycin) and only 4% were treated with a two-antibiotic regimen that included a drug active against *C. trachomatis*. The proportion of visits at which a drug effective against *C. trachomatis* was prescribed increased over the study period, however, from 32% in 1979 to 74% in 1989 ($p < 0.01$). During 1989, 21% of patients received an appropriate two-antibiotic combination.

Comment

These data suggest that the number of patients hospitalized for pelvic inflammatory disease decreased during the 1980s, whereas the number of patients being seen in physicians' offices was stable. The increased risk for women of other-than-white race remained essentially unchanged. Hospitalization rates decreased least for teenage girls who now have the highest rate of hospitalization. The cost of pelvic inflammatory disease, both in economic terms to society and in its adverse effects on the reproductive health of women, was reflected by the high frequency of surgery during hospitalizations. Trends in antibiotic treatment for ambulatory patients with pelvic inflammatory disease suggest that physicians' understanding of this syndrome has increased but substantial room for improvement remains.

These data have several potentially important limitations. First, both surveys have limited precision. This particularly limits the ability to adjust for potentially confounding variables. Second, the data may not be representative of all pelvic inflammatory disease occurring in the United States. Patients who require hospitalization may not be typical of all patients. In addition, the National Disease and Therapeutic Index, which samples only office-based private physicians, fails to track patients seen in settings such as public clinics and emergency rooms. The ratio between rates for

other-than-white and white women may be lower in the National Disease and Therapeutic Index than in the NHDS because other-than-white patients are less likely to consult a private physician for symptoms of pelvic inflammatory disease. Third, neither survey uses standard case definitions. This is a concern given the established poor positive predictive value of a clinical diagnosis.[5, 13] The diagnosis recorded at hospital discharge may be more accurate than the reported 65% positive predictive value of a clinical diagnosis, however, because of the frequent use of surgical exploration, laparoscopy, and pelvic ultrasonography.

The coding system used, the *International Classification of Diseases,* also has limitations. Whereas duration can be specified for the organ-specific diagnoses (e.g., salpingitis and endometritis), duration cannot be specified for the diagnosis most compatible with the diagnostic certainty possible in most clinical settings. Thus duration is unspecified for nearly half of pelvic inflammatory disease hospitalizations.

In spite of these problems, ICD codes for acute (acute and unspecified combined) and chronic pelvic inflammatory disease appear to measure different conditions, possibly different stages in the disease process. This conclusion is supported by the differences in age, marital status, and frequency of surgery between these two categories. Hospitalizations for chronic pelvic inflammatory disease probably represent sequelae of prior episodes of acute pelvic inflammatory disease, rather than complications of recently acquired cervical infection. As such they are an important measure of the cost of pelvic inflammatory disease for individual women and for the health care system but are unlikely to be useful for tracking the effectiveness of current prevention efforts. The combination of acute and unspecified pelvic inflammatory disease probably contains some discharges for chronic conditions but in our opinion represented the best available definition to estimate the number of and trends in cases of recently acquired infection.

The decrease in hospitalizations for pelvic inflammatory disease in the United States may indicate a decrease in the occurrence of the disease, as has occurred in Sweden.[14] This would be encouraging, especially in the face of recently reported increases in hospitalizations for pelvic inflammatory disease in England.[15] The decreasing incidence of gonorrhea since the late 1970s[16] may have led to a lower incidence of pelvic inflammatory disease.

Alternatively, the divergent trends for hospitalizations and office visits may indicate that fewer patients with pelvic inflammatory disease are being hospitalized. It is possible that pelvic inflammatory disease caused by *N. gonorrhoeae,* which is usually more clinically severe,[17] has decreased more than has pelvic inflammatory disease caused by *C. trachomatis.* This could have led to fewer patients being diagnosed with pelvic inflammatory disease or to a decrease in the proportion of patients who require hospitalization. Physicians may also be less likely to hospitalize women for treatment of recognized pelvic inflammatory disease. Hospitalizations for all conditions have decreased over this time period,[18] suggesting that changes in practice patterns may be at least partly responsible for the decrease in hospitalizations for pelvic inflammatory disease.

Several previous studies have indicated that pelvic inflammatory disease is often treated suboptimally.[19-21] Improvement has occurred as awareness of the importance of *C. trachomatis* has increased. However, according to current recommendations,[6] the majority of women are still treated suboptimally.

Prevention of pelvic inflammatory disease and its sequelae are important reasons for public health efforts to reduce the incidence of genital infection caused by *N. gonorrhoeae* and *C. trachomatis.* Accurate surveillance of pelvic inflammatory disease is needed to evaluate these programs. These data provide the best measures of occurrence in the United States. Although they offer important insights into the burden of pelvic inflammatory disease on the health care system and on the individual, important questions remain unanswered. Additional data about the epidemiology of pelvic inflammatory disease in the United States are needed. Surveillance could be improved by including cases seen in public clinics and emergency rooms, by obtaining bacteriologic data from detected cases, and by standardizing case definitions. Studies should assess the frequency and importance of clinically unrecognized, or silent, pelvic inflammatory disease. The culmination of these efforts will enable us to properly assess the effectiveness of our prevention efforts.

Mimicking low amniotic pressure by chronic pharyngeal drainage does not impair lung development in fetal sheep

Nicholas M. Fisk, MB,[a, b, d] Michael J. Parkes, DPhil,[a, c] Peter J. Moore, PhD,[a, d] Mark A. Hanson, DPhil,[a, d] Jonathan Wigglesworth, MD,[c] and Charles H. Rodeck, DSc[b, d]

Reading and London, England

OBJECTIVE: The etiology of oligohydramnios-related pulmonary hypoplasia is not understood but is known to involve chronic lung liquid loss. We tested the hypothesis that low amniotic pressure in oligohydramnios disturbs the normal tracheal-amniotic pressure gradient to increase lung liquid loss and impair lung development.

STUDY DESIGN: Chronic pharyngeal catheterization with drainage to the exterior was used in 15 fetal sheep to mimic reduced amniotic pressure at the upper airway in the presence of normal amniotic fluid volume.

RESULTS: Pharyngeal pressures relative to amniotic pressures were negative in all drained fetuses (mean ± SE −3.0 ± 0.6 mm Hg), in contrast to positive pressures in controls (0.7 ± 0.1 mm Hg). There was no significant difference in lung weight or deoxyribonucleic acid relative to body weight, or in lung morphometry, between 10 fetuses drained for 10 to 21 days and their control cotwins.

CONCLUSION: Mimicking low amniotic pressure in the upper airway by chronic fetal pharyngeal drainage does not impair lung development in fetal sheep. (Am J Obstet Gynecol 1992;166:991-6.)

Key words: Pulmonary hypoplasia, oligohydramnios, low amniotic pressure, fetal lung development, fetal sheep

Pulmonary hypoplasia, found in 15% to 21% of perinatal necropsy specimens, remains a common cause of perinatal mortality.[1, 2] Whereas inhibition of fetal breathing movements and compression by intrathoracic space-occupying lesions are known causes of pulmonary hypoplasia in both human[1, 3] and animal studies,[4, 5] the most common cause is oligohydramnios.[1] Although removal of amniotic fluid has been shown to produce pulmonary hypoplasia in numerous animal studies,[6-10] the exact mechanism by which oligohydramnios inhibits lung growth is not understood.

The mechanism of oligohydramnios-related pulmonary hypoplasia is unlikely to involve inhibition of fetal breathing movements, because fetal breathing movements continue during oligohydramnios in animals[7, 11] and their incidence is no lower in human fetuses with oligohydramnios-related pulmonary hypoplasia compared both to those with oligohydramnios and normal lungs[12] and to normal controls.[13] Compression of the thoracic cavity is also an unlikely mechanism, because amniotic pressure in severe oligohydramnios is paradoxically low[11, 14, 15] and experimentally induced abdominal compression has no effect on lung development.[16]

Normally, the upper airways produce resistance to the egress of lung liquid, creating a standing tracheal pressure of 1.5 to 3.0 mm Hg above amniotic pressure.[7, 17, 18] As lung development is impaired when this resistance is bypassed in tracheostomy experiments,[19, 20] it has been suggested that lung liquid acts as an internal stent around which the lung grows.[6, 19] Loss of lung liquid from the airways into the amniotic cavity is implicated in oligohydramnios-related pulmonary hypoplasia by the following: (1) lung volume is reduced in chronic oligohydramnios,[8] (2) tracheal ligation in experimental studies prevents the adverse pulmonary effects of oligohydramnios,[6] and (3) human fetuses with renal agenesis do not develop pulmonary hypoplasia if laryngeal atresia is also present, as in Fraser's syndrome.[21, 22]

We recently hypothesized that the mechanism causing pulmonary hypoplasia in oligohydramnios is a reduction in amniotic pressure disturbing the normal tracheal-amniotic pressure gradient, thereby increasing

lung liquid escape.[15] The aim of this study was to determine whether mimicking reduced amniotic pressure at the upper airway without creating oligohydramnios impaired fetal lung development.

Material and methods

Surgical procedure. Chronically instrumented fetal sheep were prepared as described previously[23] with standard procedures approved by the host institution and in accordance with United Kingdom legislation. Briefly, anesthesia was induced with thiopental (1 gm given intravenously) in 15 cross-bred ewes with twin pregnancies at 112 to 120 days' gestation and maintained with halothane (1.5% to 2.0% in oxygen). One horn of the gravid uterus was exposed at laparotomy and the fetal head was delivered through a uterine incision. Catheters were implanted into a fetal carotid artery, the fetal oropharynx, and the amniotic cavity. In six fetuses, a catheter was also placed into the trachea. Multiple fenestrations were fashioned at one end of a polyvinyl tube 60 cm long (inner diameter 5.5 mm), which was then fixed in the fetal oral cavity. This catheter was placed on the dorsal surface of the tongue with its tip approximately 3.5 cm posterior to the central incisors and lying at the extreme posterior margin of the tongue so as to prevent the tongue obstructing the connection between the catheter's lumen and the oropharynx. Its diameter occupied most of the cavity at this point. The lips and nares were sewn closed and sealed with cyanoacrylate glue. The pharyngeal drainage tube was filled with normal saline solution (0.9% sodium chloride), and the integrity of the pharyngeal seal isolating the pharyngeal from the amniotic cavity was confirmed. As leakage around the catheter subsequently developed in some, an additional seal was achieved in the last eight preparations by enveloping the snout in a rubber glove tied around the drainage tube. The fetus was replaced, the uterus was closed in two layers, and all catheters were exteriorized through the ewe's right flank. A collection bag, connected to the pharyngeal drain by a wide-bore polyvinyl tube 90 cm long was positioned approximately 40 cm beneath the floor of the cage. Drainage was commenced immediately. At least 5 days were allowed for postoperative recovery before recordings were made, during which time antibiotics were administered to ewe and fetus.

Catheters for fetal pharyngeal, tracheal, and amniotic pressure measurement were similarly placed for control readings in three fetuses (from three ewes at 118 to 120 days' gestation) whose upper airways were otherwise left intact.

Experimental protocol. After fetal pH and blood gas values had been shown to be normal (mean ± SEM, pH 7.35 ± 0.01, P_{CO_2} 43.1 ± 0.7 mm Hg, P_{O_2} 21.2 ± 0.9 mm Hg), pressures were measured with standard biomedical transducers attached to fluid-filled lines. Electronically subtracted pharyngeal-amniotic and tracheal-amniotic pressures were recorded for 1 hour every 2 to 3 days on a polygraph run at either 1.25 or 1.5 cm/min. The drainage bag was emptied every 2 to 3 days, and the equivalent volume of normal saline solution (0.9% sodium chloride) warmed to 38° to 39° C was infused intraamniotically. In addition, 2 ml of indigo carmine dye diluted 1:20 was added to the saline solution, so that the appearance of dye in the drainage bag gave an immediate indication of a break in the seal between the pharynx and the amniotic cavity. Dye was similarly instilled whenever the pharyngeal-amniotic pressure was > -0.5 mm Hg or when the volume of pharyngeal fluid in the drainage bag increased by >300 ml/day. Samples of the drained liquid were frozen for later viscometric analysis.

Lung specimens. The experiment was terminated on day 21 of drainage, when labor ensued, or when the dye indicated leakage. Animals were killed with pentobarbital (4 gm given intravenously), necropsy was performed, and both twins were delivered, towel dried, and weighed. Pulmonary variables were analyzed in those experiments with >10 days' drainage. The fetal tracheas were transected 0.5 cm above the carina and lung liquid was allowed to drain passively. The lungs were then removed, dissected, and weighed separately. The left main bronchus from each twin was cannulated and the left lung was inflated with buffered formalin under constant pressure (25 cm water for 30 minutes followed by 15 mm water for 11.5 hours). Five representative blocks approximately 2 mm thick were obtained from both lobes, and sections were prepared in standard fashion for morphometric study. Five fields of view per section were examined microscopically (magnification × 40) from each of five representative blocks, and the inner surface of each airspace within a 1 cm^2 sample was traced by light pen on a morphometry tablet. The mean number of airspaces counted was 57.9 ± 3.7.

For deoxyribonucleic acid (DNA) estimation, portions of right lung approximately 2 cm in diameter were harvested from each lobe, weighed (range 10 to 25 gm), and stored at −20° C. Samples were homogenized in an equivalent weight of Hepes buffer with a Polytron PCU-2 for 5 minutes and sonicated for 6 minutes, demonstrated in preliminary experiments as necessary for optimal DNA extraction. DNA was measured in duplicate as DNA/4,6-diamidino-2-phenylindole-2-hydrochloride complexes with a fluorometric microassay.[24] Laboratory specimens were coded to ensure that the DNA analysis and lung morphometry were performed blind. Two preparations with light microscopic signs of autolysis were excluded.

Analysis. In control and pharyngeally drained fe-

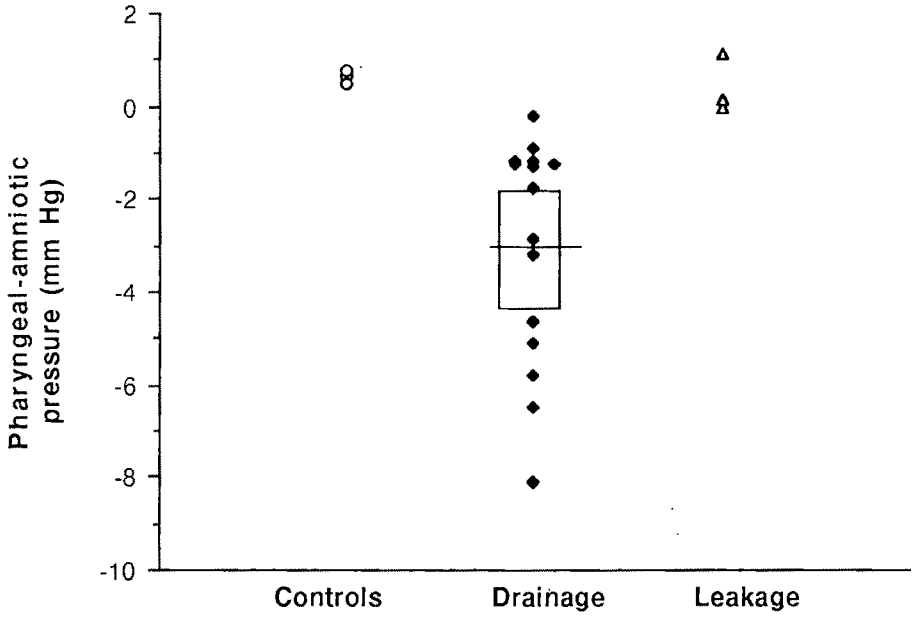

Fig. 1. Pharyngeal-amniotic pressures in three control fetuses (0) and in 15 fetuses that underwent chronic nasopharyngeal drainage (♦). *Box* indicates mean and 95% confidence intervals. Also shown are values from three drained fetuses taken on day mouth leakage was detected (△).

tuses, each minute of the pressure trace was examined for negative pressure fluctuations consistent with fetal breathing, gasping, or swallowing activity. Such minutes were excluded and point estimates of pressure were obtained at the midpoint of each minute, and a mean per hour was calculated. After exclusion of recordings obtained within 24 hours of labor or detection of mouth leakage, mean pharyngeal-amniotic pressures per drained animal were derived from a median of three recordings (range 2 to 7), and a pooled mean was calculated from the individual means per animal. Mean tracheal-amniotic pressures were similarly derived.

Viscosity was measured at 37° C with a rotating cup viscometer on a single specimen collected between days 8 and 10 of drainage from 10 fetuses. Values were then compared with those obtained in lung liquid specimens from previous experiments and stored at our institution involving chronic fetal tracheal drainage; these animals had been similarly instrumented, and the specimens were collected at comparable gestations and duration of drainage. Parametric statistics were used only where histograms confirmed a normal distribution. Pulmonary variables in the experimental twin were compared with those of the control twins by paired *t* testing; a Bonferroni correction for multiple comparisons was applied, so that differences <0.008 (0.05/6) were considered significant.

Results

Negative pharyngeal-amniotic pressures were achieved in all 15 drained fetuses, as shown in Fig. 1. Mean pharyngeal-amniotic (-3.0 ± 0.6 mm Hg) was significantly lower than 0 ($p < 0.001$) and significantly lower than that in controls (0.7 ± 0.1 mm Hg, $p = 0.02$).

The experimental period lasted ≥10 days in 10 drained animals: Two were killed on day 21, five went into labor, and mouth leakage occurred in three. Mean pharyngeal-amniotic pressure in these 10 experimental fetuses also remained significantly negative (-2.7 ± 0.6 mm Hg, $p = 0.001$) throughout the experimental period. In contrast, mean pharyngeal-amniotic pressures on the day of detection of mouth leakage was not significantly different from 0 (0.4 ± 0.4 mm Hg). The mean volume of fluid drained per day in the 10 preparations lasting ≥10 days, excluding the last recording in the three with mouth leakage, was 237 ml/day (SD = 75), significantly less than the final reading in those with mouth leakage (mean ± SD 343 ± 40 ml/day, $p < 0.05$). This fluid appeared to contain excessive mucus. Viscometry demonstrated readings that varied with shear rate (Fig. 2) and were higher than those we have previously obtained in fetal lung liquid (mean ± SD 0.75 ± 0.06 mPa), which did not vary with shear rate.

As often found in chronic fetal preparations, the body weights of chronically instrumented fetuses were reduced (by 18%) compared with those of the uninstrumented controls. However, relative to body weight, there was no significant difference between fetuses undergoing chronic pharyngeal drainage and their control cotwins in lung weight, either before or after in-

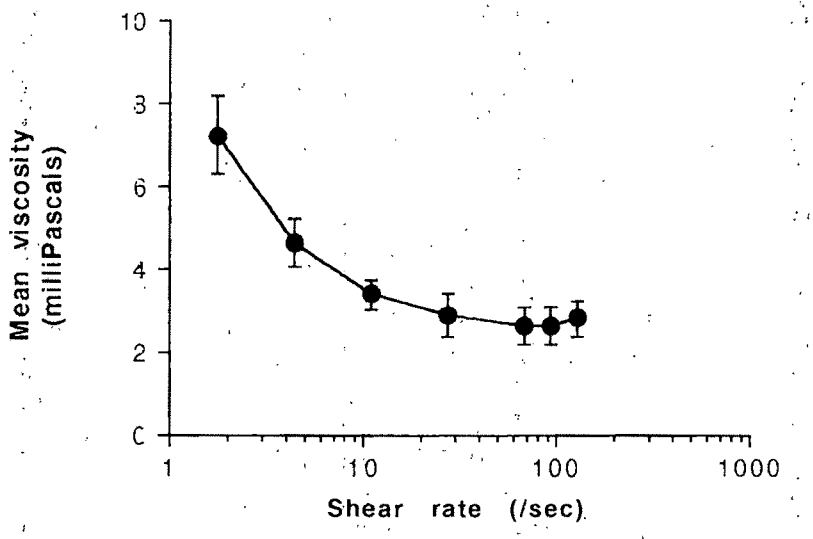

Fig. 2. Viscosity mean ± SEM in nasopharyngeal fluid collected on day 8 to 10 of drainage varies with shear rate, indicating its nonnewtonian nature.

Table I. The effect of chronic nasopharyngeal drainage on fetal lung anatomy and DNA (n = 10 unless otherwise stated)

Parameter (mean ± SEM)	*Control fetuses*	*Experimental fetuses*	*Experimental as % of control*	*Significance, p value*
Body weight (gm)	3199 ± 303	2553 ± 204	81.8 ± 5.4	0.01
Lung/body weight ratio	0.028 ± 0.001	0.027 ± 0.002	97.9 ± 7.2	NS
Left lung postinflation/body weight ratio	0.027 ± 0.001	0.027 ± 0.002	102.7 ± 7.8	NS
Right lung total DNA (mg) (n = 8)	667.7 ± 68.9	495.3 ± 57.2	78.4 ± 12.1	NS
Right lung DNA/body weight ratio (n = 8)	195.8 ± 13.8	187.5 ± 20.1	96.9 ± 10.5	NS
Lung occupied by airspaces (%) (n = 8)	65.7 ± 2.8	63.7 ± 2.5	97.5 ± 3.8	NS

The p values are shown where <0.05, although after correction for multiple comparisons values <0.008 were required for statistical significance.

NS, Not significant.

flation, or in lung DNA, as shown in Table I. In addition, lung morphometric variables were similar in control and experimental fetuses. Experimental lung/body weight ratios as a percent of control values are shown in Fig. 3 as a function of duration of drainage. When expressed as a percentage of control, there was no significant correlation between experimental lung/body weight ratio, inflated lung/body weight ratio, cross-sectional airspace area, or lung DNA/body weight ratio, with either pharyngeal-amniotic pressure or duration of drainage.

In spite of the negative pharyngeal pressure relative to amniotic pressure, tracheal pressure relative to amniotic pressure remained positive (1.7 ± 0.9 mm Hg), similar to control readings (1.5 ± 0.1 mm Hg), and significantly greater than contemporaneous measurements of pharyngeal-amniotic pressure (−3.0 ± 0.9 mm Hg, p = 0.002). Thus the increase in the tracheal-pharyngeal pressure gradient in drained fetuses (5.8 ± 1.2 mm Hg) compared with controls (0.8 ± 0.2 mm Hg, p = 0.02) was attributable to the reduction in pharyngeal pressure, rather than any alteration in tracheal pressure.

Comment

This study demonstrates that in fetal sheep mimicking the effect of low amniotic pressure on the upper airway by reducing pharyngeal pressure does not affect pulmonary development. We had previously hypothesized that a reduction in amniotic pressure of >2 mm Hg should impair fetal lung development by producing a net loss of lung fluid, because the rate of lung liquid escape would then exceed that at which lung liquid was produced.[15] Chronic fetal pharyngeal drainage in these experiments significantly reduced pharyngeal-amniotic pressure compared to controls and mimicked a drop in amniotic pressure at the laryngeal outlet of approximately 3.5 mm Hg. This was smaller than would be predicted for a column of newtonian fluid in a rigid tube in a closed system; in our in vivo experiment, however, the fetal pharynx was nonrigid, the fluid nonNewtonian (i.e., viscosity varied with shear rate)

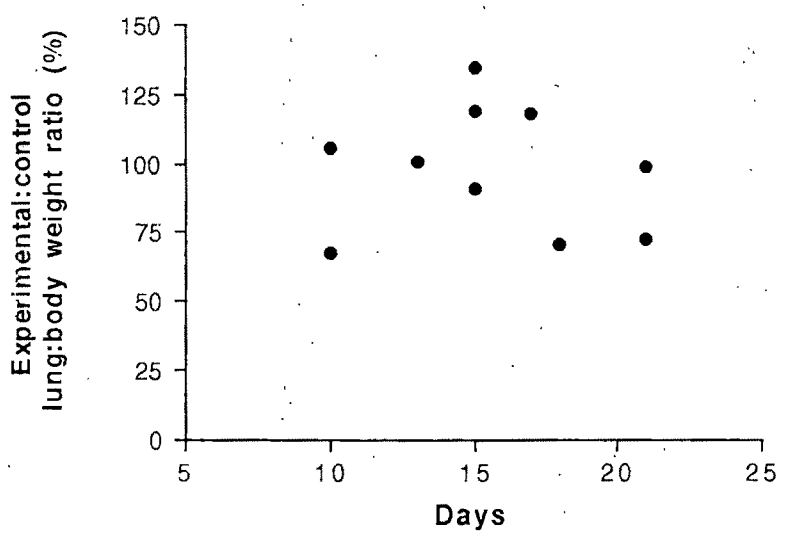

Fig. 3. Lung/body weight ratio in experimental twin as percentage of that in control twin expressed as function of duration of nasopharyngeal drainage.

and highly viscous, and the fetus continuously introducing more fluid into the system. Nevertheless, the degree of pressure reduction achieved in this study was similar to that found in human oligohydramnios[14, 15] and slightly greater than that reported in experimental oligohydramnios in the sheep.[11]

Testing our hypothesis necessitated a study design that did not produce oligohydramnios. Accordingly, we isolated the pharynx from the amniotic cavity and took care to replace the drained volume intraamniotically. A 10-day drainage period was chosen as the minimum necessary to produce detectable impairment in lung development. Fewell et al.[25] reported significantly reduced lung/body weight ratios after 10 to 22 days' phrenic denervation in six fetal lambs, three of which were subjected to this insult for ≤15 days. With the same lung processing techniques as in the current study, we recently found, by comparison with control cotwins, that 21 days' tracheal drainage reduced the lung/body weight ratio by 40%, both before and after inflation, and the lung DNA/body weight ratio and the percentage of lung occupied by airspaces by 26%.[26] None of these parameters was affected by 10 to 21 days' chronic pharyngeal drainage. Furthermore, none showed any correlation with increasing duration of drainage, which might be expected if the negative results were attributable to the minimum drainage period being too short.

The normal standing pressure in the fetal trachea is due to the resistance to egress of lung fluid provided during apnea by an active laryngeal retentive mechanism.[27-29] Bypassing this resistance in tracheostomy experiments allows free escape of fluid along the tracheal-amniotic pressure gradient, leading to equilibration of tracheal and amniotic pressures.[18, 20] The lack of effect on lung growth compared with controls in this experiment may be explained by the failure of pharyngeal drainage to alter standing tracheal pressure (which remained similar to values in our intact fetuses and those of others[7, 17, 18]). We speculate that the negative pressure generated within the fetal pharynx did not impair laryngeal retention to increase lung fluid escape; thus there was no flow-related reduction in standing tracheal pressure. The unexpectedly viscous nature of the pharyngeal fluid may have created unphysiologic conditions in the pharynx, possibly preventing any increase in lung liquid escape otherwise attributable to altered pressure gradients alone. The concentration of mucus secretions within the pharynx presumably occurred either in response to the presence of a foreign body in proximity to mucous membranes or by preventing dilution of secretions in amniotic fluid during mouth opening and swallowing.

Fewell and Johnson,[18] in contrast to other workers,[7, 17, 27-29] have claimed that the major resistance to lung liquid egress occurs not at the larynx but in the buccal cavity.[1] They found supraamniotic pressures in the buccal cavity of fetal sheep similar to those in the trachea and were able to eliminate the standing tracheal pressure with a pharyngeal tube into the amniotic cavity. The lack of effect we observed of chronic nasopharyngeal drainage at subamniotic pharyngeal pressures, both on tracheal pressure and on lung development, does not support their contention.

We thank Dr. T. Ryder of Queen Charlotte's & Chelsea Hospital, London, for advice and technical assistance with the lung morphometry, Dr. M. Rampling of the Department of Physiology, St. Mary's Hospital Medical School, London, for the viscosity studies, and Dr. J. Cunningham of the Department of Gastroenterol-

ogy, Royal Postgraduate Medical School, Hammersmith Hospital, London, for assistance with the DNA assay.

Stimulation of ovarian tumor cell proliferation with monocyte products including interleukin-1, interleukin-6, and tumor necrosis factor-α

Shu Wu, MD, Kerry Rodabaugh, MD, Otoniel Martinez-Maza, PhD, Joanna M. Watson, PhD, David S. Silberstein, MD, Cinda M. Boyer, PhD, William P. Peters, MD, J. Brice Weinberg, MD, Jonathan S. Berek, MD, and Robert C. Bast, Jr., MD

Durham, North Carolina, Los Angeles, California, and Boston, Massachusetts

OBJECTIVE: We investigated whether monocyte-derived factors could stimulate the growth of ovarian cancer cells.

STUDY DESIGN: Human peripheral blood monocytes or human monocyte–like cell lines THP-1 and U-937 were cultured with or without macrophage colony-stimulating factor, lipopolysaccharide, or phorbol myristate acetate. Culture supernatants or recombinant cytokines were assayed for growth stimulation of ovarian cancer cell lines by tritium-thymidine incorporation and direct cell counts followed by statistical analysis with Student *t* test.

RESULTS: Conditioned medium from peripheral blood monocytes or from THP-1 or U-937 cells stimulated ovarian cancer cell growth. Interleukin-1α, tumor necrosis factor-α, and interleukin-6 also stimulated ovarian cancer cell growth, whereas macrophage, granulocyte, and granulocyte-macrophage colony-stimulating factor did not. Concentrations of tumor necrosis factor, interleukin-1, and interleukin-6 in conditioned medium could not account for all the growth stimulation, and activity remained after neutralization of tumor necrosis factor, interleukin-1, and interleukin-6 with antibodies.

CONCLUSIONS: Interleukin-1, interleukin-6, tumor necrosis factor, and additional monocyte factor(s) could provide paracrine growth stimulation when monocytes are attracted to ovarian cancers that produce macrophage colony-stimulating factor. (Am J Obstet Gynecol 1992;166:997-1007.)

Key words: Monocyte, growth factor, ovarian cancer

Epithelial ovarian cancer is the leading cause of death from gynecologic malignancy.[1] Macrophages are associated with ovarian cancer cells within solid tumor implants and ascites fluid.[2, 3] Understanding the interaction between ovarian tumors and host macrophages may aid in developing novel strategies for therapy. Previous work has indicated that ovarian cancer cells can produce macrophage colony-stimulating factor (CSF),[4, 5] which augments monocytopoiesis and acts as a chemoattractant for monocytes.[6] Macrophage CSF can also act on mature monocytes and macrophages, stimulating increased production of tumor necrosis factor-α (TNF-α).[7]

TNF-α is cytotoxic or cytostatic for some but not all tumor cells. The growth of neoplastic B cells,[8] astrocytoma cells,[9] and human osteosarcoma cells[10] has been stimulated by TNF-α. The growth of human cervical carcinoma cell lines is inhibited by high concentrations of tumor necrosis factor but is stimulated by low concentrations.[11] Interleukin-1 (IL-1), another monocyte product, can stimulate growth of a human astrocytoma cell line[9] and malignant trophoblastic cells.[12] Interleukin-6 (IL-6), produced by both macrophages and tumor cells, can stimulate growth of a human myeloma cell line and may act as an autocrine growth factor for human renal cell carcinomas.[13, 14]

Although it is known that monocytes or monocyte products can stimulate the growth of ovarian tumor cells and cell lines,[15-17] the mechanism underlying this effect is not understood. The present study was undertaken to characterize monocyte-derived factor(s) that stimulate growth of ovarian carcinoma cells.

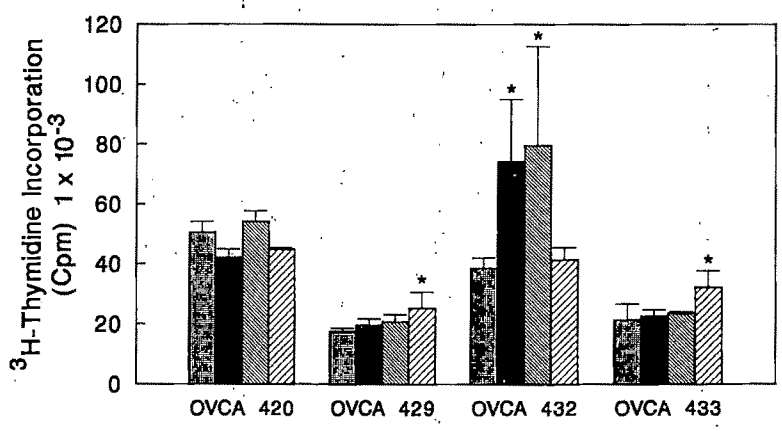

Fig. 1. ^{3}H-thymidine incorporation by ovarian carcinoma cell lines in medium conditioned by peripheral blood monocytes. Each ovarian carcinoma cell line was incubated with 0, 1%, 10% and 100% of peripheral blood monocyte–conditioned medium (*bars*, from left to right). Significant stimulation (*asterisk*) was observed with OVCA 429 ($p = 0.03$), OVCA 432 ($p = 0.01$), and OVCA 433 ($p = 0.03$).

Material and methods

Growth factors. Recombinant macrophage CSF (2×10^6 U/mg) was generously provided by Genetics Institute (Cambridge, Mass.). Recombinant granulocyte-macrophage CSF (1×10^8 U/mg) and granulocyte CSF (1×10^8 U/mg) were provided by AMGEN (Thousand Oaks, Calif.). Recombinant TNF-α (2×10^7 U/mg) was purchased from Genzyme (Boston). Recombinant IL-1α (5×10^8 U/mg) was purchased from R&D systems (Minneapolis). IL-6 (1×10^5 U/ml) was provided by Drs. T. Kishimoto and T. Hiramo (Osaka).

Chemicals. Phorbol 12-myristate-13-acetate, lipopolysaccharide from *Escherichia coli* 0127:B8, and phenyl-Sepharose CL-4B were purchased from Sigma Chemical Company (St. Louis). Tritiated thymidine was supplied by New England Nuclear (Boston).

Cell lines. Four ovarian carcinoma cell lines were used in this study. OVCA 420, OVCA 429, OVCA 432, and OVCA 433 cells were established from ascites tumor cells of patients with ovarian carcinoma.[18] The cells were grown in Eagle's minimal essential medium that was supplemented with 10% fetal bovine serum, 2 mmol/L L-glutamine, 100 U/ml penicillin, 100 μg/ml streptomycin, 1 mmol/L sodium pyruvate, and 1% nonessential amino acid mixture. Medium was changed every 3 days and tumor cells were subcultured once a week. For subculture and experiments, monolayers were detached with 0.25% trypsin and 0.02% ethylenediaminetetraacetic acid. The human acute monocytic leukemia cell line THP-1 and the human histiocytic lymphoma U-937 were obtained from the American Type Culture Collection (Bethesda, Md.). THP-1 and U-937 cells were grown in RPMI 1640 medium with 10% fetal bovine serum and antibiotics. In the case of THP-1, medium was supplemented with 5×10^{-5} mol/L β-mercaptoethanol.

Monocytes and monocyte-conditioned media. Human peripheral blood mononuclear cells were obtained by Ficoll-Hypaque discontinuous density-gradient centrifugation and washed three times in Hanks' balanced salt solution. Mononuclear cells were incubated for 2 hours in T150 tissue culture flasks at a density of 1×10^6 cells per milliliter in culture medium consisting of RPMI 1640 supplemented with 10% fetal bovine serum and antibiotics. The nonadherent cells were removed from flasks by washing three times with Hanks' balanced salt solution. The residual adherent population (peripheral blood monocytes) contained >90% monocytes judged by morphologic features after Giemsa staining and by the ability to phagocytize 1 μm latex particles. Adherent cells were incubated in culture medium or RPMI 1640 with 2 mmol/L L-glutamine and antibiotics but without fetal bovine serum. Peripheral blood monocytes were treated with different concentrations of M-CSF for 24, 48, and 72 hours or with 10 μg/ml lipopolysaccharide for 48 hours at 37° C in 5% carbon dioxide and 95% humidified air. The medium was collected, centrifuged at 205*g* for 10 minutes, and passed through 0.20 μm filters. Supernatants were stored at −20° C until used for experiments.

Media conditioned by monocyte-derived cell lines. THP-1 and U-937 cells were grown in the media described above with 10% fetal bovine serum. Cells were sedimented by centrifugation at 205*g* for 10 minutes at 20° C, washed three times with Hanks' balanced salt solution, and treated with 10 μg/ml lipopolysaccharide and 10 ng/ml of phorbol 12-myristate-13-acetate in culture medium or serum-free medium at a density of 5×10^5 cells/milliliter. After 2 days the supernatants

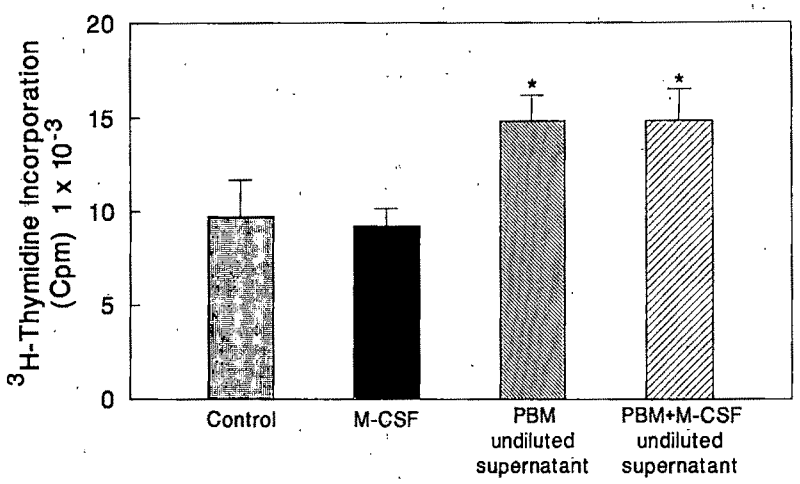

Fig. 2. Effect of macrophage CSF *(M-CSF)* on ability of peripheral blood monocytes *(PBM)* to stimulate growth of OVCA 433 cells. Peripheral blood monocyte were incubated with or without 100 ng/ml of macrophage CSF. ^{3}H-thymidine incorporation by OVCA 433 cellls was measured in presence of each undiluted conditioned medium. Macrophage CSF (100 ng/ml) was incubated with OVCA 433 as control. *Asterisk,* Significant stimulation ($p < 0.05$).

were harvested and stored under the same conditions described for monocyte-conditioned media.

^{3}H-Thymidine incorporation and cell counts. Four ovarian carcinoma cell lines were incubated at a density of 5 × 10^4 cells per 200 μl of tissue culture medium in 96-well, flat-bottomed microtiter plates. After 24 hours, the medium was removed from each well. For experiments requiring serum-free conditions, cells were washed three times with Hanks' balanced salt solution. Different concentrations of conditioned medium, cytokines, lipopolysaccharide, or phorbol 12-myristate-13-acetate diluted with tissue culture medium were added in a final volume of 200 μl. All assays were performed in quadruplicate. Cells were cultured for an additional 24 hours. Proliferation of ovarian tumor cells was measured by the addition of ^{3}H-thymidine (1 μCi per well) for the final 6 hours before harvest. After cells were labeled, culture medium was removed from each well, and cells were washed with Hanks' balanced salt solution and solubilized with 2 mol/L sodium hydroxide. Cell-associated radioactivity was measured with a Packard β-counter. For cell counts, cohort wells of ovarian carcinoma cells were incubated with growth factors and monocyte supernatant, trypsinized, and counted with a hemocytometer at 72 hours.

Biochemical characterization of the monocyte-derived growth factors. Aliquots of conditioned medium were exposed to different experimental conditions, and the residual growth-stimulating activity was measured. Heat stability was evaluated by boiling the conditioned medium for 5 minutes. Acid stability was tested by treating conditioned medium with a final concentration of 1N acetic acid (pH 2.6). Sensitivity to reduction or denaturation was assessed by subjecting aliquots of conditioned medium to a final concentration of 5% 2-mercaptoethanol, 0.1% sodium dodecyl sulfate, or 2 mol/L guanidine hydrochloride. Conditioned medium was exposed to acid or to reduction overnight at 4° C and dialyzed for 24 hours against RPMI 1640 with a dialysis membrane that retained molecules of >12 to 14 kd. The dialyzed media were diluted with culture medium and assayed for their ability to stimulate ^{3}H-thymidine incorporation by human ovarian carcinoma cell lines.

Measurement of IL-1, IL-6, and TNF-α in conditioned media. Concentrations of IL-1 were measured by bioassay with mouse thymocytes as described.[19] IL-6 was detected with enzyme-linked immunsorbent assay as described.[20] TNF-α was detected with a radioimmunoassay as described by Genzyme.

Neutralization of tumor necrosis factor, IL-1, and IL-6. Diluted conditioned medium was incubated for 2 hours at room temperature with 10^4 to 10^5 neutralizing units of polyclonal rabbit antihuman TNF-α from Genzyme or 250 to 2500 neutralizing units of goat antihuman IL-1α from R&D Systems or 10 to 100 neutralizing units of rabbit antihuman IL-6 from Genzyme. The effect on growth of ovarian tumor cells lines was measured with the ^{3}H-thymidine incorporation assay. The ability of anti–tumor necrosis factor, anti-IL-1, and anti-IL-6 to neutralize authentic tumor necrosis factor, IL-1, or IL-6 was measured in the same experiments.

Partial purification of the monocyte-derived growth factor. Ammonium sulfate was added to conditioned culture medium to provide a final concentration of 20% before separation on a phenyl-Sepharose column that had been equilibrated with 20% ammonium sulfate.

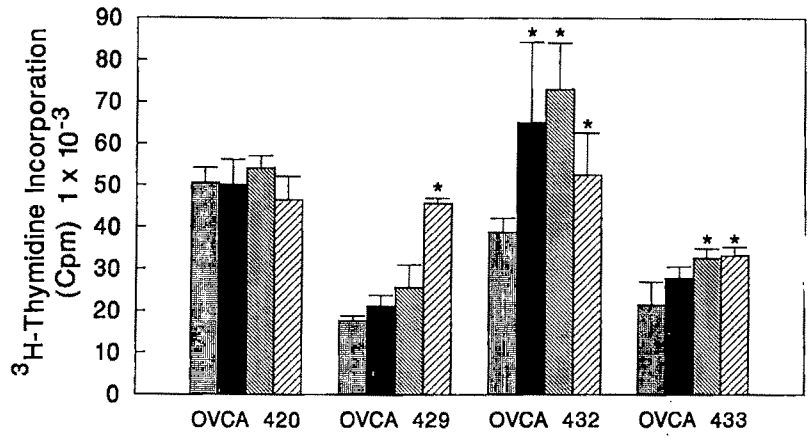

Fig. 3. ^{3}H-thymidine incorporation by human ovarian carcinoma cells in medium conditioned by peripheral blood monocytes grown in presence of lipopolysaccharide. Peripheral blood monocytes were treated with 10 μg/ml lipopolysaccharide. Each of four cell lines was grown in presence of 0%, 1%, 10%, and 100% conditioned medium, indicated by *bars* from left to right. *Asterisk,* Significant stimulation ($p < 0.05$).

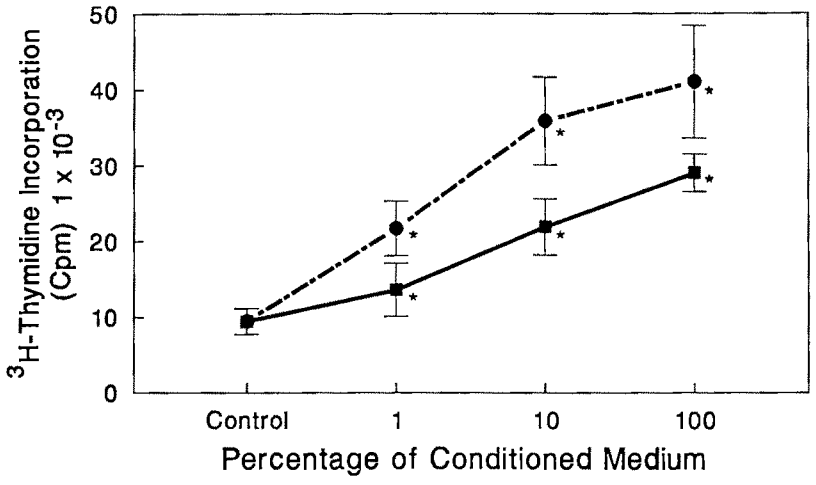

Fig. 4. ^{3}H-thymidine incorporation by OVCA 433 cells in serum-free medium conditioned by peripheral blood monocytes in the presence *(dashed line)* and absence *(solid line)* of 10 μg/ml lipopolysaccharide. *Asterisk,* significant stimulation ($p < 0.05$).

After addition of the sample, the column was washed with 50 ml of 20% ammonium sulfate in phosphate-buffered saline solution and 50 ml of deionized water. Subsequently, material was eluted with 50 ml of 5% and 50 ml of 25% ethylene glycol (Sigma). Aliquots of the eluate were dialyzed in phosphate-buffered saline solution for 24 hours at 4° C, diluted with tissue culture medium, and tested for their ability to stimulate proliferation of ovarian cancer cell lines.

Analysis. The Student *t* test was used to compare control and experimental groups. Data were expressed as mean ± SD. All assays were performed with at least four replicates.

Results

Growth stimulation of ovarian carcinoma cell lines by peripheral blood monocyte–conditioned media. Initial experiments were carried out to assess the effect of peripheral blood monocyte–conditioned medium on the growth of four ovarian carcinoma cell lines, including OVCA 420, OVCA 429, OVCA 432, and OVCA 433. The growth of OVCA 429, OVCA 432, and OVCA 433 was stimulated by peripheral blood monocyte–conditioned medium (Fig. 1). The growth-stimulating activity of the peripheral blood monocyte supernatant was not enhanced by treatment of peripheral blood monocytes for 1 to 3 days with macrophage CSF (Fig. 2). Direct addition of from 1 to 1000 ng/ml macrophage CSF to ovarian cancer cell lines did not affect growth of the ovarian cancer cells and did not enhance the stimulatory effect of peripheral blood monocyte supernatants. Neither granulocyte-macrophage nor granulocyte CSF stimulated or inhibited the growth of the four ovarian carcinoma cell lines tested (data not shown).

Enhancement of the growth-stimulating activity of

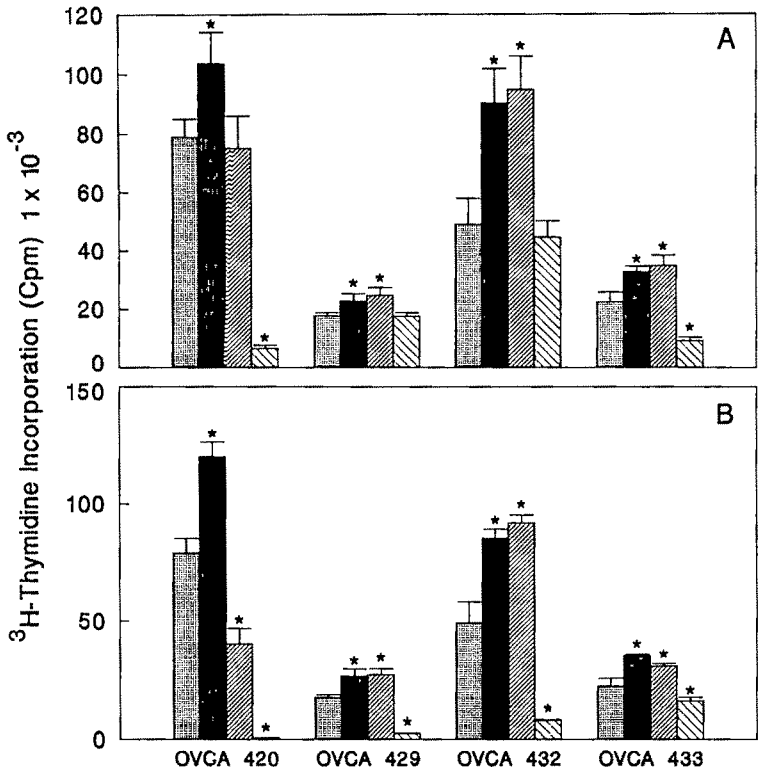

Fig. 5. A, ^{3}H-thymidine incorporation by ovarian carcinoma cell lines in medium conditioned by THP-1 cells grown in presence of 10 μg/ml lipopolysaccharide and 10 ng/ml phorbol 12-myristate-13-acetate. Each of four cell lines was grown in presence of 0%, 1%, 10%, or 100% conditioned medium, indicated by *bars* from left to right. *Asterisk*, Significant stimulation or inhibition ($p < 0.05$). **B,** ^{3}H-thymidine incorporation by ovarian carcinoma cell lines with growth medium conditioned by U-937 in presence of 10 μg/ml lipopolysaccharide and 10 ng/ml phorbol 12-myristate-13-acetate. All four cell lines could be stimulated with 1% or 10% conditioned medium, indicated by *bars* from left to right.

peripheral blood monocytes by treatment with lipopolysaccharide. When peripheral blood monocytes were treated with 10 μg/ml lipopolysaccharide, supernatants once again enhanced growth in three of four ovarian carcinoma cell lines by 55% to 159% (Fig. 3). When tested in serum-free medium, greater stimulation was noted in the presence of lipopolysaccharide than in its absence (Fig. 4). Incubation of ovarian carcinoma cell lines with 10 μg/ml lipopolysaccharide produced slight enhancement of ^{3}H-thymidine incorporation by the OVCA 420 (10%), OVCA 432 (25%), and OVCA 433 (19%) cell lines but not by OVCA 429 (data not shown).

Growth stimulation of ovarian carcinoma cell lines with media conditioned by THP-1 or U-937 in the presence of lipopolysaccharide and phorbol 12-myristate-13-acetate. The THP-1 and U-937 cell lines were established from human neoplasms of monocytic lineage. To enhance production of ovarian cancer growth-stimulating activity, both cell lines were treated with phorbol 12-myristate-13-acetate and lipopolysaccharide. The growth of all four ovarian carcinoma cell lines was significantly stimulated by low concentrations of THP-1 and U-937 products (Fig. 5, *A* and *B*). High concentrations of conditioned medium could, however, inhibit the growth of all four ovarian carcinoma cell lines (Fig. 5, *A* and *B*). In serum-free medium the growth of the four cell lines was stimulated and supernatants were active at a higher dilution (data not shown). Since phorbol 12-myristate-13-acetate and lipopolysaccharide had been added to the conditioned medium, the effect of these agents on ovarian tumor cell growth was determined in the same experiment. High concentrations of phorbol 12-myristate-13-acetate (10 ng/ml) in combination with lipopolysaccharide (10 μg/ml) could stimulate growth of OVCA 429, OVCA 432, and OVCA 433 but inhibited growth of OVCA 420 (Fig. 6). Lower concentrations of 0.1 to 1 μg/ml lipopolysaccharide in combination with 0.1 to 1 ng/ml phorbol 12-myristate-13-acetate failed to affect tumor cell growth.

The effect of TNF-α, IL-1, and IL-6 on growth of ovarian carcinoma cell lines. TNF-α and IL-1 stimulated the growth of OVCA 429, OVCA 432, and OVCA 433 (Fig. 7, *A* and *B*). To stimulate growth of OVCA 433 required >100 U/ml for TNF-α and 50 U/ml for IL-1. OVCA 429 and OVCA 432 were much more sensitive than OVCA 433 to TNF-α and IL-1. No greater

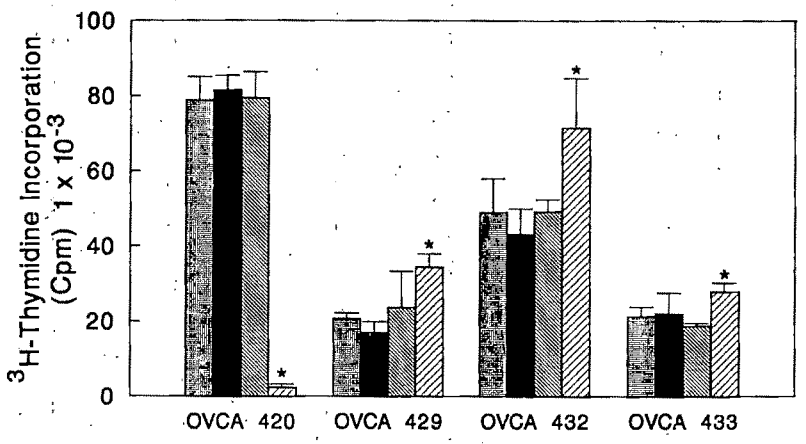

Fig. 6. Effect of phorbol 12-myristate-13-acetate and lipopolysaccharide on ^{3}H-thymidine incorporation by ovarian carcinoma cell lines. Each of four cell lines was incubated with diluent, 0.1 μg/ml lipopolysaccharide plus 0.1 ng/ml phorbol 12-myristate-13-acetate, 1 μg/ml lipopolysaccharide plus 1 ng/ml phorbol 12-myristate-13-acetate, or 10 μg/ml lipopolysaccharide plus 10 ng/ml phorbol 12-myristate-13-acetate, indicated by *bars* from left to right. Three of four cell lines, OVCA 429 ($p = 0.0004$), OVCA 432 ($p = 0.03$), and OVCA 433 ($p = 0.009$), were significantly stimulated, but OVCA 420 ($p = 0.0000003$) was inhibited by 10 μg/ml lipopolysaccharide plus 10 ng/ml phorbol 12-myristate-13-acetate.

stimulation was found at higher concentrations of TNF-α (up to 10^4 U/ml) or IL-1 (50 to 5000 U/ml). All four cell lines were slightly stimulated by 1 U/ml of IL-6 (Fig. 7, *C*). When ovarian cancer cell lines were treated with all three growth factors in combination, no additive or superadditive effects were observed (data not shown). No growth inhibition was observed after 24 hours incubation with any concentration of TNF-α, IL-1, or IL-6.

Growth of ovarian tumor cell lines was studied in the presence of 10% fetal bovine serum or under serum-free conditions. Three of the four cell lines could be stimulated with TNF-α, IL-1 or peripheral blood monocytes in either medium. Under serum-free conditions, lower concentrations of the factors were required. In the presence of serum, growth of the fourth cell line, OVCA 420, was not affected by TNF-α, IL-1, or peripheral blood monocyte–conditioned medium. In serum-free medium proliferation of OVCA 420 could be stimulated by IL-1 (Fig. 8), TNF-α, and peripheral blood monocyte–conditioned medium (data not shown). Stimulation of the growth of ovarian tumor cells was also confirmed by direct cell counts (Table I).

Concentrations of TNF-α, IL-1, and IL-6 in medium conditioned by peripheral blood monocyte and monocyte-derived cell lines. Relatively low concentrations of IL-1 (4.3 to 27.3 U/ml) and TNF-α (10 to 22 U/ml) were detected in all peripheral blood monocyte–conditioned medium (Table II). In the absence of lipopolysaccharide, IL-6 was not detected in supernatants from peripheral blood monocyte–conditioned medium (Table II). Peripheral blood monocyte–conditioned medium from three of the four donors significantly stimulated growth of three ovarian cancer cell lines. Peripheral blood monocytes from donor A in Table II, for example, stimulated growth of OVCA 429, OVCA 432, and OVCA 433 in Fig. 1. In the presence of lipopolysaccharide, peripheral blood monocytes produced significant amounts of IL-6, achieving concentrations of 19.5 to 27 U/ml (Table II). Low concentrations of IL-6 (1 U/ml) could stimulate each of the four cell lines (Fig. 7, *C*). Supernatants from peripheral blood monocytes and from lipopolysaccharide-treated THP-1 and U-937 cells contained detectable quantities of TNF-α (6 and 90 U/ml), IL-1 (1003 and 1294 U/ml), and IL-6 (0.7 and 9.5 U/ml). Antisera to TNF-α, IL-1, or IL-6 could neutralize authentic tumor necrosis factor, IL-1, and IL-6 but failed to neutralize the growth-stimulating activity of lipopolysaccharide-treated peripheral blood monocytes (Table III) or THP-1–conditioned medium (data not shown).

Characterization of stimulatory factor(s) from peripheral blood monocytes and THP-1. Several approaches were taken to characterize the factor(s) in conditioned media that were responsible for stimulating growth of ovarian carcinoma cell lines. Stimulatory activity in the supernatants of peripheral blood monocytes and THP-1 cells were destroyed by boiling for 5 minutes but remained intact after incubation overnight at pH 2.6 or in the presence of reducing and denaturing agents (Table IV). Preservation of activity after reduction and dialysis suggests that factors of >12 to 14

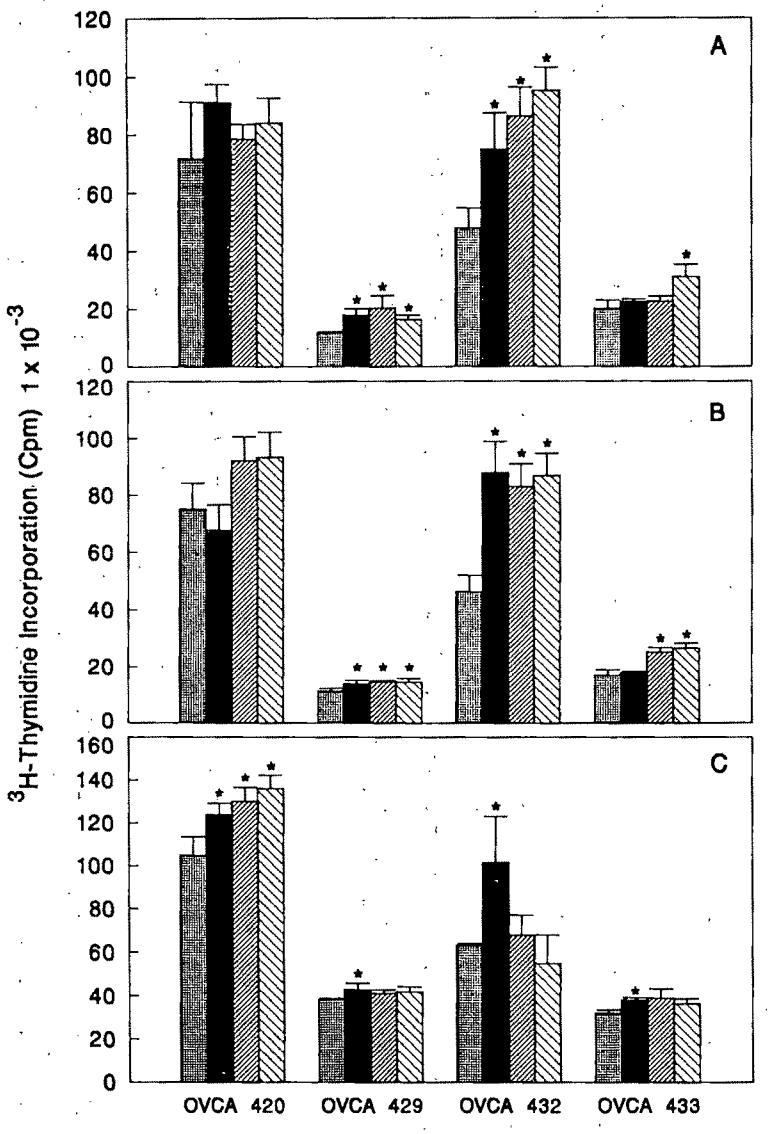

Fig. 7. A, Effect of TNF-α on ^{3}H-thymidine incorporation by ovarian carcinoma cell lines. Ovarian cancer cell lines were incubated with 0, 10, 100, and 1000 U/ml TNF-α, indicated by *bars* from left to right. *Asterisk,* Significant stimulation ($p < 0.05$). **B,** Effect of IL-1 on ^{3}H-thymidine incorporation by ovarian carcinoma cell lines. Ovarian carcinoma cells were incubated with 0, 5, 50, and 500 U/ml IL-1, indicated by *bars* from left to right. *Asterisk,* Significant stimulation ($p < 0.05$). **C,** Effect of IL-6 on ^{3}H-thymidine incorporation by ovarian carcinoma cell lines. Ovarian cancer cells were incubated with 0, 1, 10, and 100 U/ml IL-6, indicated by *bars* from left to right. *Asterisk,* Significant stimulation ($p < 0.05$).

kd are involved or that low-molecular-weight factors are tightly bound to larger moieties.

Partial purification of growth-stimulatory factors. The growth-stimulatory activity from peripheral blood monocyte and THP-1 cells could be recovered from a phenyl-Sepharose column. After washing with 5% ethylene glycol, most growth-stimulatory activity was obtained in the first 15 ml fraction. After washing with an additional 50 ml of 25% ethylene glycol, a second peak of activity was recovered (data not shown). Activity recovered from phenyl-Sepharose was retained after concentration on a YM10 (Amicon) filter and subsequent dialysis. Growth-stimulatory activity from either peripheral blood monocytes or THP-1 had similar characteristics on partial purification.

Comment

Our previous work indicated that ovarian carcinoma cell lines express macrophage CSF.[5] In our current study exogenous macrophage CSF failed to exert a di-

Ovarian cancer cells (2×10^4) were incubated in quadruplicate with above growth factors in serum-free medium, and ^{3}H-thymidine incorporation was performed at 24 hours (counts per minute, mean ± SD). SD was <15% for all conditions. Cell counts were performed at 72 hours in cohort wells (mean number of cells per well).

*Significant stimulation ($p < 0.05$).

rect effect on growth of these same cell lines. Proliferation may have been maximally stimulated by endogenous macrophage CSF. As these particular cell lines do not, however, express *fms* and do not bind macrophage CSF, it seems more likely that they lack receptors for the growth factor.

Macrophage CSF is known, however, to stimulate monocytopoiesis and to be a potent chemoattractant for monocytes. Consequently, we have examined the effect of monocyte products on growth of ovarian carcinoma cell lines. Monocytes, macrophages, and their products have previously been shown to stimulate clonogenic growth of ovarian cancer.[15-17] In this study we found that peripheral blood monocytes produced factors that stimulated the proliferation of ovarian carcinoma cell lines judged by ^{3}H-thymidine incorporation. Different ovarian cancer cell lines exhibited different responses to conditioned media from peripheral blood monocytes or monocyte-derived cell lines. OVCA 432 cells were markedly stimulated by conditioned media, even after dilution. Other ovarian cancer cell lines were less sensitive to the growth stimulatory properties of monocyte-derived factors. Lipopolysaccharide increased the production of growth-stimulatory activity by peripheral blood monocytes, producing culture supernatants with higher titer. Lipopolysaccharide alone had little effect on proliferation of the ovarian cancer cell lines, suggesting that the increased activity resulted from the effect of lipopolysaccharide on the monocytes.

The response of ovarian carcinoma cells to the stimulatory activity of monocyte-derived products is greatly influenced by the concentration of serum in the culture medium. Growth of OVCA 429, OVCA 432, and OVCA 433 was significantly enhanced by peripheral blood monocyte–conditioned medium in the presence or absence of serum. OVCA 420 cells were not sensitive to

Table II. Concentrations of TNF-α, IL-1, and IL-6 in monocyte-conditioned medium

Conditioned medium	TNF-α		IL-1	IL-6	
	ng/ml	U/ml	(U/ml)	ng/ml	U/ml
Peripheral blood monocytes (A)	0.9	18	4.3	<0.1	<0.5

Anti-tumor necrosis factor plus anti-IL-1 plus anti-IL-6					34,743 ± 1,883	44,601 ± 2,557*

Supernatants from lipopolysaccharide-treated peripheral blood monocytes were diluted 1 : 10 and incubated with 10^5 neutralizing units of anti-TNF-α, 2500 neutralizing units of anti-IL-1, 100 neutralizing units of anti-IL-6, or the three antibodies together. Similar incubations were performed with solutions of known growth factors. Supernatants were assayed for the ability to stimulate ^{3}H-thymidine incorporation into OVCA 433 cells. For tumor necrosis factor plus IL-1 plus IL-6, tumor necrosis factor = 1000 U/ml, IL-1 = 500 U/ml, IL-6 = 5 U/ml.

*Significant stimulation ($p < 0.002$).

peripheral blood monocyte–conditioned medium in the presence of 10% fetal bovine serum but could be stimulated significantly under serum-free conditions, suggesting that the peripheral blood monocyte–derived growth factor(s) could replace fetal bovine serum growth factor(s). Similar observations have been reported by Kirstein and Baglioni[10] who demonstrated that treatment with tumor necrosis factor can stimulate the growth of an osteosarcoma cell line in culture medium that contained 0.5% serum but that tumor necrosis factor was less active in the presence of 10% fetal bovine serum.

The growth-stimulating activity of TNF-α, IL-1, and IL-6 could not account for all of the proliferation observed when ovarian cancer cells were grown in medium conditioned by peripheral blood monocytes or monocyte-derived cell lines. Relatively low concentrations of tumor necrosis factor and IL-1 were detected in peripheral blood monocyte–conditioned medium. As relatively high concentrations of factors were required to stimulate growth of OVCA 433 cells, these factors alone cannot account for the magnitude of the stimulation observed. IL-6 could not be detected in medium conditioned by peripheral blood monocytes in the absence of lipopolysaccharide, yet this medium could stimulate ovarian tumor growth. Moreover,

Table IV. Characteristics of growth-stimulating activity in peripheral blood monocyte– and THP-1–conditioned medium

Treatment	*Stimulation of OVCA 433 cell growth*	
	Peripheral blood monocytes	*THP-1*
Control	+	+
Boiling 5 min	–	–
1N Acetic acid	+	+
5% β-Mercaptoethanol	+	+
0.1% Sodium dodecyl sulfate	+	+
2 mol/L Guanidine hydrochloride	+	+
Retained during dialysis	+	+

Peripheral blood monocyte– and THP-1–conditioned medium were treated as described in Material and methods. The treated supernatants were tested for their ability to stimulate ^{3}H-thymidine uptake by OVCA 433. *Plus sign,* Statistically significant stimulation of tumor growth.

growth-stimulatory activity could not be removed completely after neutralization of tumor necrosis factor, IL-1, and IL-6 with antisera that removed the activity of the authentic growth factors.

In addition to TNF-α, IL-1, and IL-6, monocytes also produce macrophage, granulocyte-macrophage, and granulocyte CSF. In our study macrophage, granulocyte-macrophage, and granulocyte CSF failed to stimulate growth of ovarian cancer cell lines. Our data are consistent with the possibility that exogenous hematopoietic factors could be administered during chemotherapy without stimulating tumor growth.

Monocyte-derived cell lines can be used as sources to purify immunologically active mediators.[21] In our study THP-1 and U-937 both produced ovarian tumor growth factor(s) similar to those produced by human peripheral blood monocytes. Treatment of THP-1 and U-937 with phorbol 12-myristate-13-acetate and lipopolysaccharide enhanced the production of factor(s) that stimulated all four ovarian tumor cell lines. Growth-stimulatory activity of THP-1 and U-937 was not due solely to the presence of phorbol 12-myristate-13-acetate and lipopolysaccharide. Phorbol 12-myristate-13-acetate alone or in combination with lipopolysaccharide stimulated the growth of OVCA 429, OVCA 432, and OVCA 433 cell lines but greatly inhibited the growth of OVCA 420. Moreover, THP-1 and U-937 supernatants were 10 to 100 times more potent than equivalent concentrations of phorbol 12-myristate-13-acetate and lipopolysaccharide (Figs. 5 and 6). The stimulatory activity of THP-1 and U-937 supernatants is abolished by heating, whereas phorbol 12-myristate-13-acetate and lipopolysaccharide are heat stable. Retention of activity within a dialysis membrane also argues against a significant role for phorbol 12-myristate-13-acetate in producing the stimulatory activity observed in supernatants from monocyte-derived cell lines. Observations in Table IV indicate that the THP-1–derived growth factor is very similar to the peripheral blood monocyte–derived ovarian tumor cell growth factor.

Thus our results indicate that macrophage-derived factor(s) can stimulate proliferation of ovarian tumor cells. Tumor necrosis factor, IL-1 and IL-6 may contribute to this growth stimulation, but additional factors are probably important. Further definition of the growth stimulating factor(s) produced by monocytes could permit development of new therapeutic strategies for this disease.

We thank Dr. F. Takatsui of Ajnomoto Co., Inc., for his kind gift of the anti-IL-6 antibodies that were used in the IL-6 enzyme-linked immunosorbent assay.

Effects of chronic maternal anemia on systemic and uteroplacental oxygenation in near-term pregnant sheep

Ellen Herget Delpapa, MD, Daniel I. Edelstone, MD, J. Ross Milley, MD, and Michael Balsan, MD

Pittsburgh, Pennsylvania

OBJECTIVE: The hypothesis of our study was that both the systemic and uteroplacental circulations would adapt to chronic maternal anemia to ensure that oxygen supply to maternal tissues would be adequate.

STUDY DESIGN: We measured cardiac output and uteroplacental blood flow and calculated systemic and uteroplacental oxygen delivery, extraction, and consumption in pregnant sheep that were anemic for 6 days (hematocrit 14%) and in normal sheep (hematocrit 28%).

RESULTS: When compared with normal pregnant sheep, anemic pregnant sheep had increases in cardiac output and uteroplacental blood flow, neither of which was sufficient to prevent systemic or uteroplacental oxygen delivery from decreasing. In spite of decreases in oxygen delivery, systemic and uteroplacental oxygen consumptions were maintained at normal levels because of increases in oxygen extraction.

CONCLUSION: Maternal systemic and uteroplacental circulations are capable of adapting well to chronic maternal anemia. (AM J OBSTET GYNECOL 1992;166:1007-12.)

Key words: Cardiac output, uteroplacental blood flow, oxygen consumption, oxygen extraction

During pregnancy the mother and fetus share the maternal oxygen supply. In situations where maternal oxygen supply is limited, both mother and fetus could be affected adversely. Maternal anemia leads to a decrease in blood oxygen concentration and may therefore reduce oxygen supply to maternal or fetal tissues. There are two basic compensatory responses that tis-

sues can make if oxygen concentration and thus oxygen supply are decreased.[1] The first response is an increase in blood flow, which serves to maintain a high capillary P_{O_2} and thus enhances the P_{O_2} gradient between capillary blood and tissues. The second adaptation is an increase in oxygen extraction, which results mainly from increases in capillary density. Increases in capillary density serve to reduce the distances across which oxygen must diffuse from capillaries to tissues. With either adaptation, oxygen transport to tissues would be enhanced.

The effects of acute anemia on maternal and uteroplacental oxygenation have been studied. In near-term sheep, uteroplacental blood flow does not change over a wide range of maternal hematocrits[2]; the principal compensatory response to acute anemia is an increase in oxygen extraction by uteroplacental tissues. In contrast, in the systemic circulation cardiac output increases during mild degrees of anemia, but with severe anemia (hematocrit $\leq$ 15%) cardiac output returns to values observed in nonanemic sheep.[3] Although these studies[2, 3] shed some light on the adaptation to anemia during pregnancy, it is quite likely that the responses to acute anemia would differ from those seen with anemias of longer duration. The most obvious reason for such a difference in response would be that some adaptative processes require time to develop. This is particularly likely in the case of the uteroplacental vascular bed, in which blood flow increases profoundly during normal pregnancy.[4] Long-term anemia might influence the development of the microcirculation to allow perfusion to increase even further. Although the uteroplacental adaptation to chronic anemia is of particular importance to fetal well-being, this regional response is only one portion of the total maternal circulatory response to anemia. It is not known whether the uteroplacental adaptation is typical or atypical of the mother's general response to anemia.

We designed the following series of studies to address two questions: (1) Does the uteroplacental response to chronic anemia differ substantially from the maternal systemic response? (2) Do the uteroplacental and systemic responses to chronic anemia during pregnancy differ from those observed with acute anemia?

Methods

We performed surgery on 11 pregnant sheep with singleton fetuses with a mean gestational age of 117 ± 3 days. The procedures to be described were reviewed and approved by the Institutional Animal Care and Use Committee of Magee-Womens Hospital. After inhalation anesthesia was induced with halothane, we cannulated a maternal hind limb artery and a vein.[2, 3] These catheters were advanced into the descending aorta and inferior vena cava. We catheterized the right and left ventricles via an external jugular vein and a carotid artery.[3] The maternal abdomen was then opened, a catheter was placed into a main vein of the uterine horn containing the fetus, and the catheter was advanced approximately 3 cm distal to the ovary.[2] All incisions were closed. Catheters were brought out subcutaneously to the sheep's flank where they were stored in a pouch.

We allowed all animals to recover for a mean of 2 days before any experiments were performed. While each animal stood unrestrained in a transport cage, we measured maternal blood pressure and heart rate continuously with Statham P23db transducers and recorded this information on a Beckman R611A polygraph recorder. We then measured systemic and uteroplacental blood flows and oxygen deliveries, extractions, and consumptions as baseline measurements in all 11 animals. To make these measurements we obtained blood samples from the descending aorta, uterine vein, and right ventricle. These samples were analyzed for hemoglobin concentration, hematocrit, blood gases and pH, and blood oxygen saturation, with standard techniques.[2, 3] We then injected 2 to 5 × 10^6 radionuclide-labeled microspheres, labeled with iodine 125, cerium 141, chromium 51, strontium 85, niobium 95, or scandium 46 (15 μm diameter) into the left ventricle while withdrawing a reference blood sample from the descending aorta at 7.9 ml/min.[5, 6]

After these baseline measurements were made, we divided the animals into two series, a control series (n = 5) and an anemia series (n = 6). In the anemia series we slowly reduced maternal hematocrit by performing isovolemic exchange transfusions with fresh sheep plasma.[3] We exchanged 500 to 1500 ml daily until the desired maternal hematocrit of about 14% was reached. We chose this hematocrit because our studies on acute maternal anemia[2] indicated that both mother and fetus could safely tolerate such degrees of hemodilution. This goal generally required 2 or 3 days of hemodilution. The amount of exchange transfusion each day was tolerated well by the pregnant sheep. The initial hematocrit and the erythrogenic response of each sheep determined the volume of exchange used eacy day and the number of days required to reduce the hematocrit to the desired level. Thereafter, the anemia was maintained by exchange transfusion either each day or every other day for 6 days. In the control group several animals underwent sham exchange transfusions. Fetal viability was documented periodically during the study period by ultrasonographic visualization of fetal heart activity. At the end of the 6-day experimental period we repeated the measurements of maternal systemic and uteroplacental blood flows and oxygen deliveries, extractions, and consumptions as described above.[2, 3]

Table I. Effects of 6 days of anemia on some maternal hematologic variables

	Control		*Anemia*	
	Baseline	*After 6-day study period*	*Baseline*	*After 6-day study period*
Gestational age (days)	118 ± 2	126 ± 2	118 ± 3	126 ± 3
Body weight (kg)	59 ± 7	59 ± 7	60 ± 7	60 ± 7
Hematocrit (%)	28 ± 2	28 ± 4	29 ± 3	14 ± 1*
Hemoglobin concentration (gm/dl)	9.7 ± 0.5	8.9 ± 1.3	9.5 ± 1.2	4.6 ± 0.5*
Arterial blood oxygen concentration (ml/dl)	12.2 ± 0.8	11.2 ± 1.5	12.2 ± 1.5	5.8 ± 0.9*

For control studies $n = 5$; for anemia studies $n = 6$. Values are means ± SD.

*Significant difference after 6-day study period (anemia) versus baseline measurements. Note that the baseline data of the control series did not differ significantly from any of the baseline data of the anemia series.

When the experiments were completed, each sheep was killed with an overdose of sodium pentobarbital. All maternal organs were dissected, during which time catheter placements were verified visually. The uterus, placental cotyledons, placental membranes, and fetus were removed and weighed; all tissues were then incinerated at 280° C for 48 hours. The resulting tissue ash was packed into counting vials, and the amounts of each radionuclide in each organ and in the reference blood samples were measured with a γ-scintillation counter (model 1185R, Tracor) and a 1024 channel pulse-height analyzer (Ultima II, Norland). Nuclide isotope separation was performed by computer, which used a least-squares fitting analysis to determine the amount of each isotope in each sample (Nova 3, Data General; average error in calculation of corrected radioactive counts per minute of each isotope = 5%).[2, 3, 5]

We calculated cardiac output as follows:

$$\text{Cardiac output} = (\text{cpm}_{\text{total}}/\text{cpm}_{\text{ref}}) \cdot Q_{\text{ref}}$$

where $\text{cpm}_{\text{total}}$ is the total radioactive counts per minute injected in the left ventricle,[3] cpm_{ref} is the radioactive counts per minute in the reference blood sample, and Q_{ref} is the reference withdrawal rate from the maternal descending aorta.

We computed uteroplacental blood flow as follows:

$$\text{Uteroplacental blood flow} = (\text{cpm}_{\text{up}}/\text{cpm}_{\text{ref}}) \cdot Q_{\text{ref}}$$

where cpm_{up} is the radioactive counts per minute in the uterus plus placenta. The remaining abbreviations are the same as those previously given.

We calculated systemic and uteroplacental vascular resistances as the mean arterial blood pressure divided by the cardiac output or the uteroplacental blood flow, as appropriate. These calculations represent the total resistance (i.e., the sum of changes in resistance caused by reduced viscosity plus those caused by active vasoregulation) across either the systemic or uteroplacental circulation.

We calculated blood oxygen concentration (Hemoglobin concentation × 1.34 × Blood oxygen saturation), and then used the Fick principle to calculate systemic and uteroplacental oxygen deliveries, extractions, and consumption, as follows[2, 3]:

$$\text{Oxygen deliveries} = \text{blood flow } (CaO_2)$$

$$\text{Oxygen consumption} = \text{blood flow } (CaO_2 - C_vO_2)$$

$$\text{Oxygen extraction} = (CaO_2 - C_vO_2)/CaO_2, \text{ or oxygen consumption/oxygen delivery}$$

where blood flow denotes cardiac output or uteroplacental blood flow, CaO_2 is the arterial blood oxygen concentration, and C_vO_2 is the oxygen concentration in mixed venous blood (right ventricular or uterine venous blood, as appropriate).

An analysis of variance was used to compare measurements obtained in control animals with those obtained in anemic animals.[7] Raw data, as well as data calculated as percent change from baseline data, were analyzed. When significant differences were found, appropriate nonparametric tests were used to identify these differences. A p value ≤ 0.05 was used to indicate significance. In instances of borderline significance we used paired t tests to compare the experimental data with the baseline measurements, both in the control series and in the anemic series. Because several comparisons were being made simultaneously, we used lower p values of ≤ 0.01 to establish statistical significance.

Results

Baseline measurements (shown in Tables I, II, and III) obtained in the animals in the control series did not differ significantly from those obtained in the animals in the anemic series, with two borderline exceptions: Uteroplacental blood flow ($p = 0.05$) and uteroplacental oxygen delivery ($p = 0.07$) were lower in the anemic animals than in the control animals during the control period. Because the 11 animals were distributed randomly into either the control or the anemia series, these differences were most likely a result of sampling (biologic) variability. In the control animals receiving sham transfusions, there were no differences in any of the variables measured when compared with the con-

Table II. Effects of 6 days of anemia on maternal systemic circulation and oxygenation

	Control		*Anemia*	
	Baseline	*After 6-day study period*	*Baseline*	*After 6-day study period*
Cardiac output (ml/min/kg)	137 ± 27	144 ± 20	130 ± 31	184 ± 40*

Table III. Uteroplacental blood flow and oxygenation during chronic maternal anemia

	Control		*Anemia*	
	Baseline	*After 6-day study period*	*Baseline*	*After 6-day study period*
Uteroplacental blood flow (ml/min)	930 ± 114	1034 ± 232	738 ± 196*	1020 ± 177†
Uteroplacental vascular resistance (mm Hg/ml/min)	0.11 ± 0.03	0.09 ± 0.03	0.13 ± 0.02	0.09 ± 0.02†
Uteroplacental oxygen delivery (ml/min)	112 ± 13	118 ± 37	91 ± 29†	58 ± 10†
Uteroplacental oxygen consumption (ml/min)	32.2 ± 1.8	31.1 ± 5.7	27.9 ± 7.3	26.3 ± 4.2
Uteroplacental oxygen extraction (%)	30 ± 4	26 ± 4	33 ± 10	45 ± 4†
Uterine venous blood P_{O_2} (mm Hg)	52 ± 4	54 ± 5	51 ± 6	45 ± 5†
Fetal weight (kg)	—	3.7 ± 0.4	—	3.1 ± 0.3
Uteroplacental weight (kg)	—	1.3 ± 0.9	—	1.3 ± 0.9

For control studies $n = 5$; for anemia studies $n = 6$. Values are means ± SD. Note that all values for blood flow and oxygenation are raw data uncorrected for maternal weight.

*Comparisons of two baseline measurements between control and anemia series were of borderline significance: uteroplacental blood flow, $p = 0.05$; uteroplacental oxygen delivery, $p = 0.07$.

†Significant difference after 6-day study period (anemia) versus baseline measurements.

trol animals that did not receive sham transfusions, and thus those data were pooled.

Table I shows the effects of 6 days of anemia on several hematologic variables. The anemic animals had reductions in their hematocrits and hemoglobin concentrations of about 55%. Because arterial blood oxygen saturations were unaffected by the anemic state, arterial blood oxygen concentration decreased an amount comparable to the hemoglobin reduction (52%). Table II summarizes the maternal systemic response to anemia of 6 days' duration. In the anemic animals cardiac output increased an average of 42%. This increase was the result of increases in heart rate and in stroke volume. Mean arterial blood pressure in the control baseline state was higher than usual at 108 ± 17 mm Hg, because one animal was spontaneously hypertensive. In spite of this degree of hypertension, this animal was included in the data analysis because all of the remaining variables measured were indistinguishable from those of the other control animals. Maternal mean arterial blood pressure was unaffected by anemia, whereas calculated systemic vascular resistance decreased an average of 33%. In spite of the increase in cardiac output, systemic oxygen delivery decreased about 37% during the anemia. Although oxygen delivery decreased, chronic anemia did not affect systemic oxygen consumption, because systemic oxygen extraction increased sufficiently as compensation. The increased oxygen extraction was reflected by a decrease in mixed venous blood (right ventricular blood) P_{O_2}.

Table III summarizes the changes that took place in the uteroplacental circulation in response to anemia of 6 days' duration. In response to anemia, uteroplacental blood flow increased approximately 35%, in association with a 28% decrease in calculated uteroplacental vascular resistance. The increase in uteroplacental blood flow was not sufficient to prevent uteroplacental oxygen delivery from decreasing an average of 35%. In response to this decrease in oxygen delivery, oxygen ex-

traction increased sufficiently for uteroplacental oxygen consumption to be maintained. Associated with the increased uteroplacental oxygen extraction was a reduction in uterine venous blood Po_2.

Comment

The purpose of our experiments was to answer two questions. First, is the uteroplacental adaptation to 6 days of maternal anemia similar to that seen in the systemic circulation? Our data show that maternal anemia produces an adaptation in the uteroplacental circulation that is typical of the systemic circulation as a whole. In both circuits, perfusion increased, although the increase was insufficient to maintain oxygen delivery (Blood flow × Arterial blood oxygen concentration). Without another compensation, both uteroplacental and systemic oxygen consumptions would have decreased. We found that oxygen extraction in both circulations increased sufficiently for oxygen consumption to be maintained. The increases in perfusion of about 35% to 40% were most likely principally a result of reductions in whole blood viscosity induced by the hemodilution. This response is similar to what has been reported for the systemic circulation of the nonpregnant animal[8, 9] where as much as 40% of the increase in systemic blood flow as a result of anemia can be attributed solely to the viscosity-reducing effects of a 50% reduction in hematocrit.[9] Our data clearly show that the increases in uteroplacental perfusion were not the result of increases in perfusion pressure, an important short term regulator of uteroplacental blood flow,[10] because mean arterial blood pressure was unaffected by 6 days of maternal anemia.

Alternatively, it is possible that the increases in systemic and uteroplacental perfusions with anemia were principally the result of active vasoregulation rather than the consequence of reduced viscosity. For example, the drop in mixed venous blood Po_2 that we observed after 6 days of maternal anemia suggests that a potent stimulus for active vasoregulation (decreased tissue Po_2[1, 2] leading to vasodilatation locally or chemoreceptor stimulation peripherally) is present in many vascular beds, in addition to the uterine bed (where uterine mixed venous Po_2 is decreased, Table III). Indeed, the decline in calculated vascular resistance in both the systemic and uteroplacental circulations would seem to support such a view of active vasodilation resulting from 6 days of anemia. Yet this is not necessarily true. The concept of vascular resistance (Mean perfusion pressure/Mean blood flow) as an indicator of vasoconstriction or vasodilation requires, among other things, that hematocrit does not change.[11] When hematocrit varies, resistance to blood flow must be considered by Poiseuille's law to be a function of two components[5]: (1) viscosity, which changes in a predictable manner with anemia, and (2) the cross-sectional area of the various vascular beds, which may or may not change with anemia.[9] Because we did not measure viscosity (the measurement of which is fraught with numerous theoretic and methodologic problems), it is impossible to determine whether any or all vascular beds were involved in active vasoregulation during anemia.

Table IV. Differences in uterine venous and umbilical venous blood Po_2 as function of duration of maternal anemia

	Uterine venous blood Po_2 (mm Hg)	*Umbilical venous blood Po_2 (mm Hg)*
Acute maternal anemia	37 ± 3	18 ± 3
Chronic maternal anemia	45 ± 5*	26 ± 4*

Data on acute anemia are taken from reference 2 ($n = 4$). Data on chronic anemia (6 days' duration) are from unpublished observations made in six near-term pregnant sheep. Values given are means ± SD at maternal hematocrit of 14% ± 1%.

*$p < 0.05$ (unpaired t test), chronic versus acute maternal anemia.

We also wanted to answer a second question: Is the circulatory adaptation to chronic anemia during pregnancy different from that seen with acute anemia? With respect to this question our data indicate that the circulatory response to 6 days of anemia differs both qualitatively and quantitatively from the response to acute anemia in near-term pregnant sheep. With acute anemia we found that cardiac output increased initially as hematocrit was reduced, but at hematocrits <15% cardiac output decreased toward values seen in nonanemic control animals.[3] In the current studies we reduced maternal hematocrit to 14% (or about 50% of control levels) and found that cardiac output was approximately 40% higher than in the control state at the end of the 6-day study period. The difference between the response of cardiac output to acute and chronic anemia suggests that duration of anemia appears to play an important role in the adaptation to the anemic state. It is possible that chronic anemia produces a release of a variety of vasoactive humoral substances, which could lead to long-term increases in perfusion to a variety of vascular beds. It is also possible that the increase in cardiac output is solely the result of reductions in viscosity in the absence of any changes in vascular tone.[5, 9] During acute anemia in nonpregnant animals, for example, reductions in hematocrit of about 50% (similar to those obtained in our studies) lead to reductions in viscosity that are of sufficient magnitude to account for about a 40% increase in perfusion.[9] However, with acute anemia in pregnant sheep, the lack of an increase in cardiac output at hematocrits ≤14% sug-

gests that many vascular beds must have actively vasoconstricted.[3] This predominance of vasoconstriction during acute anemia could have accounted for the lack of increase in blood flow that would have been expected simply as a result of the reduction in apparent viscosity. In contrast, in the chronically anemic state, in which cardiac output increased about 40%, if some regional circulations vasoconstricted during chronic anemia, this response would have to be counterbalanced by vasodilatory responses in other vascular beds to account for the increased cardiac output.

Any difference in the uteroplacental response to acute anemia versus chronic anemia has important implications for the fetus. In response to reductions in hematocrit, tissue perfusion or oxygen extraction or both may increase as a means of adapting to reductions in oxygen availability.[1] When oxygen extraction is used as the principal or sole adaptation to oxygen deficiency in any given vascular bed, the magnitude of the increase in oxygen extraction is reflected by the extent of the reduction in P_{O_2} of the mixed venous blood draining that vascular bed.[2] In the case of the uterine vascular bed, as uteroplacental oxygen extraction increases, uterine venous blood P_{O_2} decreases. Because the placenta of the sheep, as well as that of the human species, functions as a concurrent exchanger,[10] any reductions in uterine venous blood P_{O_2} will be associated with equivalent reductions in umbilical venous blood P_{O_2}.[11-13] Thus any condition that leads to increases in oxygen extraction across the uterine vascular bed will inevitably lead to reductions in umbilical venous blood P_{O_2} (i.e., fetal hypoxemia).[13] During chronic anemia, in contrast to the situation seen with acute anemia, the increase in uteroplacental blood flow that occurs along with the increase in oxygen extraction serves to minimize the reduction in uterine venous blood P_{O_2} that would otherwise result from chronic anemia. Table IV illustrates the implications of this principle. The table provides preliminary data on the uterine venous and umbilical venous blood P_{O_2}s of four animals made anemic for a short time (data from reference 2) compared with six sheep made anemic for a longer time (unpublished data). At a maternal hematocrit of 14% (± 1 SD), both uterine and umbilical venous blood P_{O_2}s were lower with acute anemia than with chronic anemia. Thus, for the same degree of maternal anemia, chronic anemia is associated with less fetal hypoxemia than is acute anemia. This difference in adaptation is due entirely to the augmented uteroplacental perfusion that is associated with chronic anemia but is lacking with acute anemia.

In summary, the current data indicate that the response of the uteroplacental circulation to 6 days of maternal anemia is qualitatively and quantitatively similar to that seen in the systemic circulation. In both circulations, anemia is associated with increases in perfusion and in oxygen extraction to maintain oxygenation. The response to anemia of 6 days' duration differs strikingly from that seen with acute anemia and suggests that duration of anemia plays an important role in the circulatory adaptation to anemia during pregnancy. These results could have important implications for our understanding of the effects of chronic anemia on human pregnancy.

We thank Anthony Battelli, Mike Bodenheimer, Vincent Santucci, and Lynn Heckman for their valuable technical assistance.

Analysis of peripheral blood of pregnant women for the presence of fetal Y chromosome–specific ZFY gene deoxyribonucleic acid sequences

Shu-Min Kao, BS,[a] Gu-Ching Tang, MS,[a] T'sang-T'ang Hsieh, MD,[b] Kung-Chia Young, MS,[c] Han-Chow Wang, MD,[d] and Chia C. Pao, PhD[a]

Taipei and Tainan, Taiwan

Deoxyribonucleic acid sequences of human ZFY (zinc-finger-Y) gene, a Y-chromosome–specific gene and candidate for the testis-determining factor, has been identified by an in vitro enzymatic deoxyribonucleic acid amplification method in peripheral blood specimens of women pregnant with male fetuses. This technique permits detection of ZFY gene deoxyribonucleic acid sequences in as few as a single male cell among 1,000,000 female cells. Maternal blood results were confirmed by amplification of ZFY gene deoxyribonucleic acid sequences in chorionic villus cells and by karyotyping in 33 of 36 pregnant women. There was no false-positive male result, and two of the three blood specimens with false-negative results were obtained from pregnant women at a very early gestational age. With properly designed guidelines, this deoxyribonucleic acid amplification method may be an alternative to determine the fetal sex for those pregnancies at risk for X-linked genetic disorders. (Am J Obstet Gynecol 1992;166:1013-9.)

Key words: ZFY gene, polymerase chain reaction, peripheral maternal blood, fetal sex determination

Transfer of nucleated fetal cells into maternal circulation in early pregnancy has been a controversial issue in the past.[1, 2] Such a phenomenon is of great interest because fetal cells isolated from maternal blood, obtainable by venipuncture, should be a potentially very valuable source for the prenatal diagnosis of fetal genetic abnormalities. Morphologic observations led the way in early studies on the presence of fetal cells in maternal circulation. Recent reports with monoclonal antibody technologies have suggested that fetal trophoblast cells and nucleated erythrocytes are found in the peripheral blood of pregnant women,[3-5] but the procedures to isolate these cells are laborious and cells recovered are often either too few or not homogeneous enough to be used in conventional biochemical or genetic analysis.

Deoxyribonucleic acid (DNA) amplification catalyzed by thermostable DNA polymerase and directed by flanking oligonucleotide primers is a very powerful method for amplifying extremely small amounts of target DNA.[6, 7] Polymerase chain reaction may provide us with enough sensitivity to identify and analyze fetal genes when the numbers of fetal cells in maternal blood are too few for other types of analyses. There were two major goals in our attempts to develop a DNA amplification protocol to detect fetal DNA sequences from peripheral blood of pregnant women in early pregnancy. Our first goal was to demonstrate unequivocally the presence and abundance of fetal cells in the blood of pregnant women. With a human Y-chromosome–specific gene as a model for our investigation, our second goal was to examine the feasibility of prenatal determination of fetal sex with maternal blood. This objective is important and may become very useful in the management of more than 130 X-linked genetic disorders, such as classic hemophilia and Duchenne and Becker muscular dystrophy. Amplification-based methods have been used in the identification of human Y-chromosome–bearing cells in blood samples from pregnant women bearing male fetuses.[4, 8-12] However, results of these earlier reports were either negative[8] or complicated by a number of things such as a high false-positive rate,[9] autosomal cross-reactivity of the Y-specific primers used,[9, 13] contamination,[9, 11] and previous pregnancies.[14]

The results reported in this study demonstrated that

cells of fetal origin can be found in the circulating blood of pregnant women in early pregnancy. Our results also suggested that with properly engineered primers and carefully controlled amplification conditions it is feasible to detect the presence of DNA sequences of single-copy genes on fetal Y chromosome and to determine the fetal sex with peripheral blood of pregnant women by our DNA amplification method.

Material and methods

Sample preparations. After informed consent was obtained from subjects, venous blood specimens were collected in Vacutainer (Becton Dickinson, Rutherford, N.J.) blood collecting tubes containing ethylenediaminetetraacetic acid from male and female laboratory staff members and from 36 pregnant women who underwent chorionic villus sampling, because of advanced maternal age, between 8 and 12 weeks of gestation. Blood was always collected before chorionic villus sampling to avoid the possibility of trophoblast cells being released into the circulation as a consequence of the procedure. DNA was purified from chorionic villi and peripheral blood mononuclear cells by phenol and chloroform extraction and recovered by ethanol precipitation before being subjected to DNA amplification.

Amplification of zinc-finger-Y (ZFY) gene DNA sequences. DNA purified from equivalent to approximately 1 ml of whole blood or from two chorionic villi was used for the amplification of ZFY gene DNA sequences with thermostable *Taq* DNA polymerase in a thermal cycler apparatus (Perkin-Elmer Cetus, Norwalk, Conn.). Procedures for the amplification and subsequent detection of amplified DNA were similar to those we have reported earlier,[15-17] with the following modifications to include the nested amplification. Briefly, the 100 μl DNA amplification reaction mixture contains 10 mmol/L Tris hydrochloride, pH 8.3; 50 mmol/L potassium chloride; 1.5 mmol/L magnesium chloride; 0.01% gelatin; 20 pmol each of the two primers; 2.5 nmol each of the four deoxyribonucleotide triphosphates; 1 U of *Taq* DNA polymerase (Perkin-Elmer Cetus), and specimen (positive) or control (negative) DNA. The temperature of the reaction mixture was first raised to 94° C for 1 minute to denature the DNA and then cooled down to 55° C for another minute to allow annealing of primers to putative target DNA sequences. This procedure was followed by raising the temperature to 72° C for 1 minute to extend the DNA chain. The whole process was repeated 32 times with a 10-minute incubation at 72° C at the end. The nested polymerase chain reaction uses a second set of primers located inside the DNA, flanked by the initial or first set of primers, and uses the amplified products resulting from the first amplification as a template. The nested amplification both increases the overall sensitivity and enhances the specificity of polymerase chain reaction by minimizing false-positive results. For the nested amplification of ZFY gene DNA sequences, 2 μl of the first amplified mixture was subjected to the same amplification procedures, except for 40 cycles in a freshly prepared 100 μl reaction mixture containing the same components as the first polymerase chain reaction and the new set of nested primers. The sequences of primers were derived from DNA sequences of the human ZFY gene which is located on the Y chromosome and which is a candidate for the testis-determining factor and has been suggested to be associated with the initiation of testis differentiation during embryogenesis.[18] The selection of oligonucleotide primers was performed with a computer program for efficient amplification by polymerase chain reaction.[19] Sequences of the first set of primers (from 5′-end to 3′-end), which flank a 354-base-pair region of the human ZFY gene on the Y chromosome, are CCATTTGTTCTAAGTCGCCA (2125 nucleotide) and CTTCAAGGCCAACATCAGCTG (2478 nucleotide). The sequences of the nested primers are CTCTCAGTTCACACAAAGG (2149 nucleotide) and GCTTGTAGACACACTGTTAGG (2455 nucleotide), which flank a 307-base-pair region located inside the primers used in the initial amplification.

Establishment of human ZFY gene DNA sequence positivity. After the nested amplification, one tenth of the amplified reaction mixture was separated by electrophoresis in 2% agarose gel containing 0.5 μg/ml ethidium bromide and visually inspected under ultraviolet light for a DNA band of 307 base pairs to determine the human ZFY gene DNA sequence positivity. The amplified ZFY gene DNA was further analyzed by restriction endonuclease digestion and by Southern blot DNA hybridization with an internal oligonucleotide probe. The internal oligonucleotide (TTCATACAAAAGACTATCCTCATCGGTG) was labeled at its 5′-end with γ-phosphorus 32-adenosine triphosphate by polynucleotide kinase to approximately 5×10^6 counts/min/pmol of oligonucleotide and used for Southern blot analysis. Procedures for Southern blot hybridization have been described previously by others[20] and were modified for oligonucleotide probes as follows: After hybridization, the filters were washed sequentially in 2× SSC (1× SSC is 0.15 mol/L sodium chloride and 0.015 mol/L sodium citrate) and 0.5% sodium dodecyl sulfate twice for 10 minutes each at room temperature and then in 0.1× SSC and 0.5% sodium dodecyl sulfate three times for 20 minutes each at 55° C. Restriction endonucleases were purchased

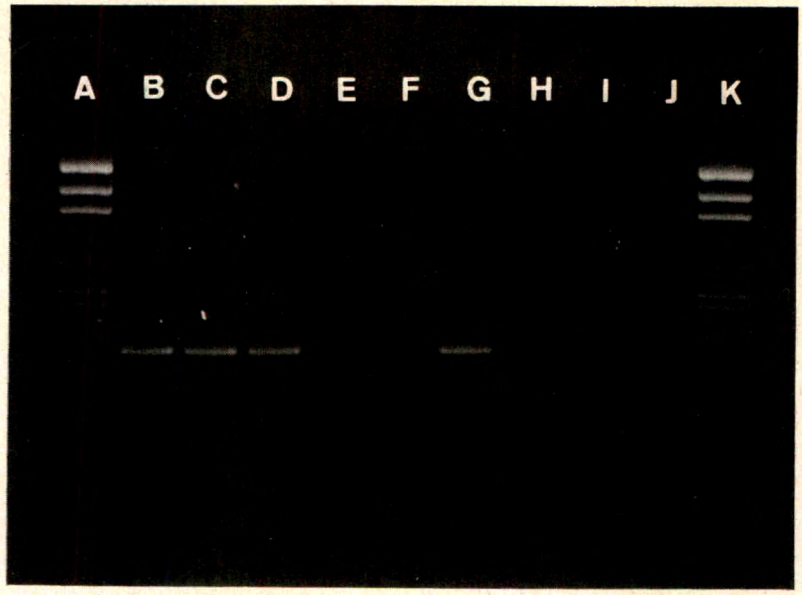

Fig. 1. Detection of ZFY gene DNA sequences by DNA amplification. Sequences of primers and procedures for sample preparation and amplification are described in Material and methods. pGEM-3 DNA digested with a mixture of restriction endonucleases *Hin*fI, *Rsa* I, and *Sin* I was used in *lanes A* and *K* as size standards, and sizes are (from top to bottom) 2645, 1605, 1198, 676, 517, 460, 396, 350, 222, 179, 126, 75, 65, 51, and 36 base pairs. *Lanes B, C,* and *D* are amplifications of 1 ng and 100 and 10 pg of human genomic DNA prepared from peripheral blood mononuclear cells of a male volunteer, equivalent to approximately 200, 20, and 2 cells, respectively. *Lanes E* and *F* are amplifications of 10 and 1 μg of genomic DNA prepared from cells of a female volunteer, equivalent to approximately 2×10^6 and 2×10^5 cells, respectively. *Lanes G* and *H* are amplifications of DNA prepared from chorionic villus cells obtained from women who bore male *(lane G)* or female *(lane H)* fetuses. *Lanes I* and *J* are amplifications of 1 ng bacterial cell *E. coli* and 50 ng mouse DNA, respectively.

from either Boehringer Mannheim (Mannheim, Germany) or BRL (Gaithersburg, Md.) and used according to the manufacturers' recommendations.

Precautions against contamination and false-positive results in polymerase chain reaction. Because of the exquisite amplification power of the polymerase chain reaction procedures, precautionary measures were necessary to minimize any possibility of contaminations including sample-to-sample contaminations and polymerase chain reaction product carryovers. These measures include wearing and frequent changing of disposable gloves during all procedures that involve specimen handling and processing, aliquoting of all reagents, physical separation of locations for pre– and post–polymerase chain reactions, use of closed-end blood collection tubes (Vacutainer), and meticulous laboratory techniques. Because of the nature of the target DNA, all experimental procedures in this study were performed by female staff members of the laboratory. Furthermore, all reagents were irradiated with ultraviolet light to inactivate any contaminating double-stranded DNA that may have been present before sample DNA was added and the polymerase chain reaction started.[21] Fifty nanograms of human female DNA (from equivalent to approximately 7500 cells) or 1 ng of *Escherichia coli* DNA (equivalent to approximately 200,000 bacterial cells) was used as a negative control that always yielded negative results. Multiple reagent controls were also included in each polymerase chain reaction assay, giving negative results. Repeated DNA amplification assays of the same specimens at different times or performed by different laboratory members produced the same results.

Results

The amplification of ZFY gene DNA sequences flanked by the primers used in this study is indicated by the presence of the 307-base-pair DNA after nested amplification (Fig. 1). The sensitivity and specificity of this amplification procedure were determined by the amplification of serial dilutions of human genomic DNA of known concentrations prepared from peripheral blood mononuclear cells of male and female individuals. As few as 10 pg of genomic DNA from equiv-

DNA shown in *panel A* was transferred onto nitrocellulose membrane filter and hybridized to ^{32}P-labeled oligonucleotide probe as described in Material and methods. Exposure time was 25 minutes at room temperature without intensifying screen.

alent to approximately fewer than two peripheral blood mononuclear cells of a male subject consistently produced a clear positive signal (Fig. 1, lane D). Negative results with practically no visible background smears were obtained with the amplification of ≥10 μg DNA obtained from equivalent to approximately 2 million peripheral blood mononuclear cells of a female subject (Fig. 1, lane E). Chorionic villus cells from one woman who bore a male fetus and one who bore a female fetus produced positive and negative results, respectively (Fig. 1, lanes G and H). The primers used in this study do not cross amplify DNA of bacterial *E. coli* or mouse cells (Fig. 1, lanes I and J).

The specificity of amplification and the authenticity of the amplified DNA were further evaluated by two additional and independent methods. First, the putative amplified ZFY gene DNA was subjected to digestion by restriction endonucleases. When the 307-base-pair DNA generated by the nested amplification (Fig. 2, *A*, lane B) was treated with restriction endonuclease *Mae* II or *Nde* I, the original DNA disappeared and was replaced with DNA fragments of 168 and 139 base pairs (Fig. 2, *A*, lane C) or 223 and 84 base pairs (Fig. 2, *A*, lane D), respectively. The sizes of these DNA fragments match precisely with the sizes deduced from known DNA sequences and sites of the restriction endonuclease. The specificity of the amplification was further confirmed by Southern blot hybridization with an internal oligonucleotide probe. The 307-base-pair putative human Y-chromosome DNA and the 139- and 223-base-pair DNA fragments generated by *Mae* II and *Nde* I restriction endonuclease digestion, respectively, hybridized with the internal oligonucleotide probe (Fig. 2, *B*). These results are also in complete agreement with the locations of the *Mae* II and *Nde* I restriction sites with respect to that of the probe sequence.

The ability of the primers and amplification protocols used in this study to identify extremely small numbers of male cells in the presence of large numbers of female cells was demonstrated by mixing female and male cells at different ratios. Amplified ZFY gene DNA could be visualized directly in agarose gel stained with ethidium bromide when DNA was prepared from a mixture containing a few male cells and 1×10^6 female cells (Fig. 3, lanes B to E). The actual amplification of ZFY gene DNA sequences from peripheral blood of pregnant women was illustrated with the blood of two women who bore male fetuses (Fig. 3, lanes F and G) and one woman with a female fetus (Fig. 3, lane H).

Finally, the results of the amplification of ZFY gene

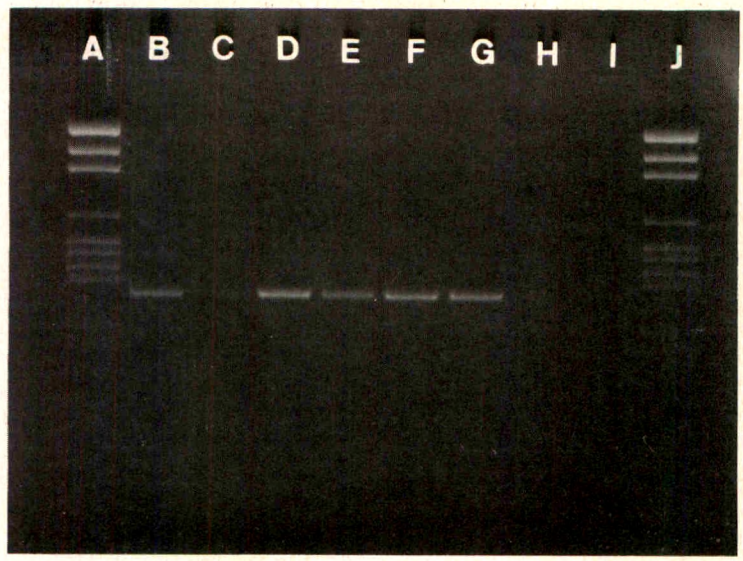

Fig. 3. Amplification of ZFY gene DNA sequences with DNA prepared from mixture of peripheral blood mononuclear cells of male and female fetus at different ratios. DNA size standards in *lanes A* and *J* are same as described in legends to Figs. 1 and 2. *Lanes B* and *C*, 10^6 Female cells mixed with 10 and 1 male cells, respectively. *Lanes D* and *E*, 10^5 Female cells mixed with 10 and 1 male cells, respectively. *Lanes F* and *G* are amplifications of ZFY gene DNA sequences of DNA prepared from peripheral maternal blood specimens of two pregnant women carrying male fetuses. *Lane H* is from woman carrying female fetus. *Lane I* is DNA-negative control.

DNA sequences from peripheral blood of 36 pregnant women were compared with those of the amplification of ZFY gene DNA sequences of chorionic villus cells and with karyotyping (Table I). Twenty and 13 pregnant women were found to be positive and negative, respectively, for the presence of ZFY gene DNA sequences in both peripheral blood and chorionic villus cells. Amplification of ZFY gene DNA sequences in chorionic villus cells agreed with the results of karyotyping in all 36 cases. Three women showed Y-chromosome DNA sequences in chorionic villus cell amplification but not in blood specimens, even with up to five times the starting amount of DNA. Two of these three women were at <8 weeks of gestation at the time the chorionic villus sampling and blood specimens were taken. All 20 blood specimens in Y-chromosome DNA–positive patients were confirmed by the presence of Y-chromosome DNA sequences in their chorionic villus cells and also by karyotyping. Four babies have been born so far, all male, and all four have been identified earlier by the amplification of Y-chromosome DNA sequences with the blood of the mothers during pregnancy.

Comment

Identification of fetal cells and determination of the presence of Y chromosome–specific DNA sequences in the peripheral blood of pregnant women in early pregnancy can be very valuable for individuals at risk for recessive X-linked disorders that typically affect only hemizygous male subjects. In some of these disorders prenatal diagnosis is possible by chorionic villus sampling or amniocentesis followed by cytogenetic, biochemical, or molecular analysis of the recovered fetal cells. Because the gene or genes responsible for most of the recessive X-linked disorders have not yet been identified, the only other alternative to prenatal diagnosis in these cases is to determine the gender of the fetus. If the fetus is either affected by the genetic defect or of male gender, termination of pregnancy can be an option. Standard karyotyping and cytogenetic analysis of chorionic villus cells or amniocytes to detect the Y chromosome depend on obtaining multiple high-quality metaphases from cells cultured for days to weeks before analysis. Maternal blood combined with DNA amplification may be an alternative that is much faster, more accessible, and even safer than the current invasive chorionic villus sampling and amniocentesis.

Polymerase chain reaction DNA amplification has correctly determined the presence of the Y-chromosome–specific DNA sequence in single cells obtained from in vitro fetilized, preimplantation human embryos,[22] which has led to the successful transfer of female embryos to mothers who were carriers of serious X-linked disorders.[23] Various reports have put the numbers of fetal cells in maternal blood at one fetal cell in every 1000 to 40,000 maternal cells.[4, 5, 10] On the basis of these estimations and judging from the capability of our method to detect one male cell in 1,000,000 female cells (Fig. 3), the primers and protocols used in our study should be able to pick up Y-chromosome DNA sequences in circulating maternal blood of women pregnant with male fetuses. Enrichment of fetal cells in maternal blood by monoclonal antibodies[9] or other means does not seem necessary for the detection of Y-chromosome DNA sequences.

Blood specimens of two of the three women with positive results for ZFY gene DNA sequences in chorionic villus cells but negative results in blood were obtained at a very early gestational age (<8 weeks). Blood specimens from the same two women were positive when tested again at 10 and 11 weeks' gestation, respectively. This observation seems to suggest that the gestational age may be an important factor in determining the availability of fetal cells after transfer to the maternal circulation. If only blood specimens from pregnant women at ≥8 weeks' gestational age were tested, the current method was correct in determining the fetal sex in 33 of 34 cases. The absence of any false-positive result, however, is a great asset because this test will probably be used mainly to identify male instead of female fetuses in pregnancies at risk for X-linked recessive genetic disorders. An excellent positive predictive value of the test will assure identification of all that may be affected by the genetic marker. Other advantages of this test over karyotyping or DNA probe hybridization of chorionic villus cells or amniocytes are that this test can be performed much earlier than amniocentesis and that the tests can be completed in less than a day because the automated DNA thermal cycler instrument does most of the work and does not require isotopes.

There are a number of restrictions before the current method can be used for routine screening purposes. Strict but workable guidelines to control the problem of contamination need to be explored and investigated, including precautions generally applicable to all polymerase chain reactions and specific ones to guard against false-positive results with regard to Y-chromosome–specific sequences.[24] Other issues, such as the effect of previous pregnancies and the occasional presence of Y-chromosome–specific sequences in XY female subjects,[12] also need to be examined. For this and other similar amplification-based methods used for the prenatal diagnosis of genetic disorders, separation of fetal from maternal cells is probably needed[3, 4] because only then could fetal or maternal origin of a given genetic disease marker be distinguished. As the method exists now, only sex determination and paternally derived disease marker analysis are feasible. In any event prenatal diagnosis of increasing numbers of genetic disorders in early pregnancy with maternal blood and preimplantation embryos is becoming available.

In summary, we have shown that with carefully engineered primers, well-designed protocols, and strictly controlled anticontamination measures the detection of ZFY gene DNA sequences and determination of fetal sex with maternal blood obtained in early pregnancy is possible.

We acknowledge the encouragement and support of Dr. Chau-Hsiung Chang and Dr. Delon Wu. We thank Dr. Cagge C. Lee of Dr. Lee's Women's Hospital for valuable discussions. The technical assistance of Ms. Bin-Ying Wang in some experiments is also gratefully acknowledged.

First report: Telemetry-assisted ambulatory nonstress test to evaluate umbilical cord compression

To the Editors: The resting nonstress test is performed with the pregnant patient supine and inactive. Fetal heart rate accelerations in association with fetal movement suggest fetal well-being. In addition to accelerations the baseline fetal heart rate should decline toward term from 150 to 120 beats/min.[1] But what about the patient outside the office who is active, ambulatory, and erect? To evaluate this influence, two patients with suspected umbilical cord compression (based on 36 weeks' fetal heart rates of 140 to 150 beats/min) were assessed in both the supine and erect positions. The classic nonstress test differed from the ambulatory nonstress test. A telemetry unit (model no. 80240A, Hewlett Packard, Palo Alto, Calif.) recorded active and resting fetal heart rates. Obvious differences were observed between the two tests (Fig. 1). Continued observation with telemetry and hospitalization of these patients between 36 and 38 weeks' gestation verified the heart rate changes. Both patients were delivered of infants with umbilical cord entanglements and related cord compression. One patient also had a vas insertion of the cord.

The supine-inactive nonstress test may give mislead-

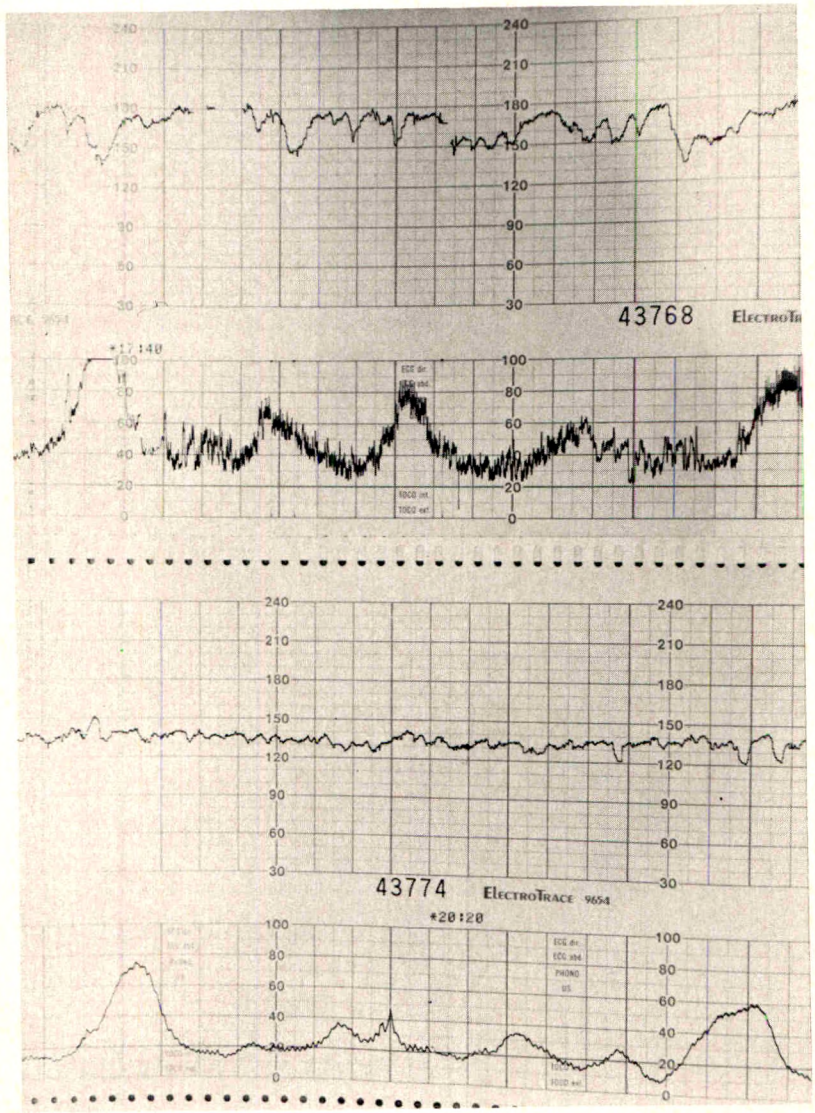

Fig. 1. Nonstress tests of patient A at 37 weeks' gestation recorded with telemetry during ambulation (*top*, 43768) and supine rest (*bottom*, 43774).

ing results in borderline cases of fetal compromise. Clinically suspected compromised fetuses can go undetected, with supine nonstress tests showing fetal acceleration with movement. A compromised fetus may be detected with a telemetry-assisted ambulatory nonstress test.[2]

Frequency of positive antinuclear antibody test results in women with recurrent spontaneous abortions

To the Editors: The recent article by Xu et al. (Xu L, Chang V, Murphy A, et al. Antinuclear antibodies in sera of patients with recurrent pregnancy wastage. AM J OBSTET GYNECOL 1990;163:1493-7) from The Johns Hopkins Hospital suggests that women with "unexplained" consecutive pregnancy losses are much more likely (40%) than controls (pregnant 8.2%, nonpregnant 5.6%) to have a positive antinuclear antibody test result. This proportion of positive antinuclear antibody test results is markedly higher than that found by most others in the literature.[1,2] We recently published a prospective, controlled study of antinuclear antibody tests in 277 women with recurrent pregnancy losses and found that 16.3% of cases had a positive titer at ≥1:40.[2] In 299 pregnant controls, however, 16.6% had a positive antinuclear antibody test result, and 16.8% of 119 nonpregnant control patients had a positive antinuclear antibody test result. Our results agree with those of Petri et al.,[3] who found positive antinuclear antibody test results (using HEp-2 cells) in 16% of cases compared with 20% of controls. These results are quite different from those of Xu et al. Such differences in clinical studies can often be explained by differences in patient selection. Xu et al. reported on results from 30 women with "explained" pregnancy losses and 30 with "unexplained" pregnancy losses over a 39-month period. The neat matching of these two numbers suggest that some patient selection was involved, although the authors did not address that point in their Material and Methods section. Did the 30 patients in their group A constitute the entire population of patients with unexplained recurrent pregnancy losses seen from August 1984 to November 1987? Did the 30 patients in their "explained pregnancy loss" group constitute a remarkably coincidental number of explained recurrent pregnancy losses? If not, how were the patients in these groups chosen?

Since they apparently used a technique and target cells (HEp-2) similar to ours, can they explain this striking difference in which nearly half of the 60 women had a positive antinuclear antibody test result? If the proportions are correct, this difference suggests that a positive antinuclear antibody test result does not discriminate between patients with recurrent pregnancy losses, whether their pregnancy losses are explained (53.3% positive test result) or unexplained (40% positive test result). Did the authors conclude therefore that the "explanation" for the pregnancy losses is really not entirely correct?

Finally, the authors suggested that "the screening test for antinuclear antibodies in patients with recurrent fetal wastage should be considered." While that may be true, a single antinuclear antibody test is not a satisfactory screening procedure for autoimmune disease. Rather one must ask questions about a history of signs and symptoms to ascertain the presence of autoimmune disease.

Reply

To the Editors: We thank Dr. Harger for his comments and careful review of our recent article, but we also wish to respond to the issues that he raises in his letter. Our study began with a review of 60 patients with repeated pregnancy losses who had completed an evaluation while under our care between August 1984 and November 1987. The frequency of unexplained pregnancy losses is quite high, having been reported to be 37% to 44%[1,2]; therefore we were not surprised at finding a 50% rate of unexpected losses in our patient population, especially when this was what we had already observed from clinical experience before 1983.[3] No attempt was made to preselect or match cases.

We, too, were surprised at the high frequency of low-positive antinuclear antibody titers in our pregnancy loss groups, but we were most reassured after comparable results for antinuclear antibody titers were obtained from two different laboratories on the same blood samples. Furthermore, the frequency of low-positive antinuclear antibody titers noted in our nonpregnant group (5.6%) agreed with data from Fritzler et

al.,[4] who assayed sera taken from 2500 female blood donors.

One conclusion that can be drawn from our study is that low-titer antinuclear antibody sera might reflect repeated losses rather than serve as a *cause.* Alternatively, low-positive-titer antinuclear antibody sera may represent a "cross-reaction" for an as yet unidentified immunologic cause of pregnancy losses. For these reasons we believe that antinuclear antibody screening *should* be considered for patients with repeated pregnancy losses.

Prophylactic sacrospinous fixation discouraged

To the Editors: I strongly object to your publication in the Clinical Section of Cruikshank's article (Cruikshank SH. Sacrospinous fixation—Should this be performed at the time of vaginal hysterectomy? AM J OBSTET GYNECOL 1991;164:1072-6).

This article appeared in a previous issue of your JOURNAL.[1] It was presented to the Central Association of Obstetricians and Gynecologists and it received a full discussion (which was also published) by Dr. George Morley. Dr. Morley pointed out that the prophylactic performance of sacrospinous ligament fixation of the vaginal vault during hysterectomy in women with the potential for pelvic relaxation is unwarranted. The authors report that the incidence of vaginal vault prolapse after hysterectomy ranges from "2 to 45%." Certainly most authorities, including these authors in their previous publication, would agree that this incidence is highly overstated.[1-4] Moreover, in most reported series the incidence is certainly below 5%.[1-4]

Other complications have been reported variously, including two deaths from this procedure.[1, 5] Sacrospinous ligament fixation is not an innocuous procedure and should not be advocated for prophylaxis. Moreover, this procedure should be performed only by those who have had specialized training in its performance, as it poses several other risks, including but not limited to sciatic nerve injury, segmental nerve loss, and profuse bleeding.

I therefore object to the publication of this Clinical Opinion based on the experience of one author. Perhaps in Dr. Cruikshank's hands this operation goes smoothly, as he states in his previous article with an average operating time of 18 minutes.[1] To translate his facility in this procedure to advocacy of its usage by other practitioners with varying surgical skills may be dangerous.

In conclusion, I do not agree with the use of vaginal vault sacrospinous ligament fixation in patients with potential vault prolapse or potential pelvic weakness and would agree with Dr. Morley in his previous criticism that Dr. Cruikshank's position is certainly not warranted and may be downright dangerous.

I appreciate the opportunity to express this opinion and welcome the author's comments.

Reply

To the Editors: I appreciate the interest Dr. Scotti has shown in my article. I will answer his questions individually.

Prophylaxis means to prevent, to ward off. It *does not* mean routine. This has been misinterpreted. After several letters and a formal request to possibly publish a Clinical Opinion, I felt that I should do so, to clear up this misunderstanding. I want to reiterate, as I published in *Surgical Profiles,* January 1991 (Merck Sharp and Dohme), that only 8% of the patients in my own population met the criteria for this adjunct fixation. The number increased to 35% when outside surgical referrals were added. The 43% incidence of vault prolapse noted in the original article on sacrospinous fixation stems from the 1960s literature.

I am fully aware that sacrospinous fixation is not an innocuous procedure and should not be a *routine* procedure. Prophylaxis is not routine. All defects of the vagina should be corrected at the initial operation or failure and complications can occur. Bleeding, nerve injury, etc., are serious complications, and some patients die. Before acceptance of Dr. Scotti's article on massive small bowel evisceration at the time of sacrospinous fixation, as a reviewer I asked these questions: Were the patients evaluated for multiple defects and were these corrected at the initial surgery? Was

there a missed enterocele? Had the vaginal vault been closed? Prevention is the key that we strive to achieve.

This Clinical Opinion was not based solely on my experience. After supportive letters and an invitation to write this Clinical Opinion, I saw the need. Those wishing to learn this procedure should do so from experienced teachers; they should learn the anatomy and the pelvic floor defects in patients with these kinds of problems. I believe that every patient should be *thoroughly* evaluated for all defects. These should be corrected at the time of hysterectomy, not as a piecemeal procedure whereby the patient will have to undergo several operations.

In conclusion, I say that the sacrospinous ligament fixation is a good adjunct procedure in patients who have multiple defects of the vaginal wall. I have described criteria for patients at risk for vaginal vault prolapse as a result of these defects. When learned appropriately, under the right supervision, sacrospinous fixation at the time of hysterectomy can be a perfect adjunct to the surgical armamentarium.

Again, I thank Dr. Scotti for his comments.

Polyunsaturated fatty acids in preeclampsia

To the Editors: The interesting article of Wang et al. (Wang Y, Kay HH, Killam AP. Decreased levels of polyunsaturated fatty acids in preeclampsia. AM J OBSTET GYNECOL 1991;164:812-8) deals with the present problem of polyunsaturated fatty acids and hypertension, in relation to preeclampsia. This is an aspect that has hitherto received little attention. The authors found significantly lower levels of polyunsaturated acids and of linoleic and eicosapentaenoic acids and suggest that the reduced levels of the latter may play a significant pathophysiologic role in preeclampsia.

In a study performed in Spain as early as 1979,[1] in 14 women with preeclampsia and their newborn infants and 14 control women and their newborn infants, we found significantly lower levels of linoleic acid among women with preeclampsia (29.4% vs 23.3%), as Wang et al. report. Unfortunately the laboratory techniques at that time did not permit determination of *n*-3 eicosapentaenoic and docosahexaenoic fatty acids. However their precursor, linolenic acid (reduced in the work of Wang et al.), showed no differences.[1]

However, our work did present some facts about polyunsaturated fatty acids in newborn infants of preeclamptic mothers that may be worth reporting now. The aforementioned differences in linoleic acid among the mothers were found, but there were no differences in linoleic acid or in the other fatty acids analyzed among newborns from preeclamptic mothers and those from controls. There was only one newborn infant whose mother had a very low level of linoleic acid and the umbilical cord level of linoleic acid was at the lower limit of normality.

Nevertheless, bearing in mind the significance of linoleic acid as a precursor of more elongated *n*-6 fatty acids, which are necessary for brain development and prostanoid synthesis,[2] we think linoleic acid should receive more attention in the study of the pathophysiologic features of preeclampsia. In accordance with this, the remarkable difference in total polyunsaturated fatty acids reported by Wang et al. depends fundamentally on the difference on linoleic acid.

In summary, we think that, without underestimating *n*-3 fatty acids, the *n*-6 class should receive more attention. Finally, we would like to put a question to the authors, in the light of their relevant findings and ours: Do they think that reduced fatty acid levels are primarily of maternal origin, with some kind of active transfer to the fetus, or could it be that there is an increased fetal consumption in preeclamptic pregnancies?

Reply

To the Editors: Sanjurjo et al. pose an interesting question. It is not known whether the decreased levels of fatty acids we found in the preeclamptic patients in our study are due to maternal factors (i.e., decreased intake, decreased mobilization from body stores, or increased metabolism) or to increased fetal consumption. Since preeclampsia is a pregnancy-related disease, a fetal factor certainly may be important. Essential fatty acids, which include linoleic and linolenic acids, are important for fetal growth and development because they are incorporated into phospholipids that are necessary for cell membrane synthesis. They are known to be transported across the placenta in increasing amounts with advancing gestation. Cord blood levels of linoleic acid are reported to be lower than maternal levels. The relatively lower level of linoleic acid in fetal blood facilitates maternal-fetal transport across the placenta.[1] The reason for a possible increase in the transport across the placenta or for an increase in fetal requirements for these polyunsaturated fatty acids in preeclampsia is not known and would require further investigation.

There is, in fact, another possible drain on these maternal fatty acids and that would be the placenta, which is known to synthesize and metabolize large amounts of eicosanoids. It has been shown that placental production of thromboxane is actually increased in preeclampsia.[2] Since linoleic acid is a precursor of thromboxane, it would be possible to explain the decreased maternal plasma levels of linoleic acid by the enhanced synthesis of this vasoconstrictor in the pla-

centa. We agree with the need for further studies on these important fatty acids.

Sex selection and early pregnancy fetal sex determination: Ethics and personal freedom of choice

To the Editors: This letter pertains to an article in the April 1991 issue of the JOURNAL (Evans MI, Drugan A, Bottoms SF, et al. Attitudes of the ethics of abortion, sex selection, and selective pregnancy termination among health care professionals, ethicists, and clergy likely to encounter such situations. AM J OBSTET GYNECOL 1991;164:1092-9).

I would like to point out an "apparent change of heart" in the ethical perspective of John C. Fletcher, PhD, formerly of the National Institutes of Health, who wrote in the Sounding Board section of *The New England Journal of Medicine*, Sept. 6, 1979, page 550, in the article "Ethics in amniocentesis for fetal sex determination, and whom I quoted previously[1]:

> I have reevaluated my position on this issue as a result of participation in the Hastings Center study group in consultation with the staff from the prenatal diagnostic centers of The Johns Hopkins Hospital and their policy on amniocentesis for sex choice. In my revised view, it is not ethically required that physicians withhold amniocentesis (*or for that matter, new reproductive technologies such as Fetal Sex Determination in Early Pregnancy by FASA,** italics added) from fully informed parents who may use the results in deciding to abort for sex choice. Even though the physician may personally disapprove of the request (*I have personally and publicly stated that my personal private preference is not in favor of abortion using Fetal Sex Determination in Early Pregnancy by FASA for female fetal sex "feticide,"* italics added), it is fairer to the parents to grant it, within the limits of availability of amniocentesis (*or other new reproductive technologies such as FASA*, italics added). Physicians who agree with the social, ethical perspective that informs the legal rules on abortion will finally want to keep faith with the moral intent of the law. Policy makers in this field should now reconsider their obligation to be responsive and consistent in their beliefs. I include myself in the company of those who need to be changed.

The implications of the change of ethical principles in the 1991 article are directly opposite the 1979 writings of John C. Fletcher, PhD, and I wonder how it is possible to explain such a complete reversal in published ethical principles.

*FASA (Fetal Anatomic Sex Assignment) is a service mark of John D. Stephens, MD.

It is my opinion that the only issue that is the sole responsibility of physicians really is support of the patient's (and it is usually women who are burdened with this responsibility) right to exercise her (or, in the instance of a couple in a counseling situation, their) reproductive options, regardless of the indication, regardless of the personal moral or ethical standpoint held by the practicing physician.[2-6] I have previously stated my own personal perspectives on all aspects of this subject.[1,5-8] Quite clearly, genetic counseling to people of a "traditional society" requires sensitivity. Borgaonkar[9] stated: "I strongly support the suggestion that genetic counselors take into consideration societal factors in conducting premarital or preconceptual counseling, not only in a traditional society but also in any society."

Reply

To the Editors: Dr. Stephens presented a long quotation from one of us (J.C.F.), dated Sept. 6, 1979. In 1979, Dr. Fletcher said that whereas he had previously been opposed to prenatal diagnosis specifically for sex selection, he thought at the time that physician preferences should take a back seat to patient desires. Over the course of the past decade, however, there has been a restabilization, with the pendulum swinging from complete physician authority, through to patient autonomy, and now settling back in again somewhere in the middle. The results of our survey of more than 700 professionals suggest that whereas the majority of this group is ethically accepting of the notion of termination of pregnancy, there is, in general, significant resistance to the use of such technology for sex selection as the only issue. Note that these are *ethical* questions, not legal ones. It is perfectly consistent to be of the opinion that something is unethical but yet should still be legal. Such

is the general interpretation of our own data. Speaking as authors rather than as summarizers of the data, we believe that sex selection crosses the line between the use of technology for genetic reasons and its use for eugenic reasons. We believe that no physician need participate in any action for which he or she feels uncomfortable. Such is different from saying that a patient cannot have such a service or supporting refusal to provide a referral. We find it difficult to understand how Dr. Stephens can accept Dr. Fletcher's change of position from that in the 1979 reference but now doesn't understand how that position could again be changed. Ethics evolve with technology and experience. Our writings speak for themselves.

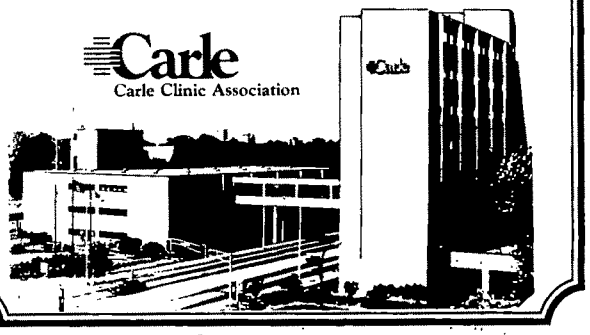
PERINATOLOGIST
ALASKA

Outstanding practice opportunity for 1-2 BC/BE perinatologists to develop perinatal services at the only Level III perinatal center in Anchorage. The center has an active perinatal transport program that draws from the whole state (11,000 births). The NICU is staffed by 6 in-house neonatologists. Components of the job include primary patient care, medical leadership for the perinatal center, maternal transport and outreach education to referral hospitals. Support staff for clinical research is also available.



Competitive salary and benefits program available through affiliation with neonatology group. Anchorage offers excellent recreational opportunities with the advantage of the amenities of a city.

Please send letter of interest with CV to Jack Jacob, M.D., Alaska Neonatology Associates, P.C., 3340 Providence Drive, Suite 366, Anchorage, Alaska 99508 or call (907) 563-3026.

Medical College

The Aga Khan University Hospital is now in its seventh year of operation. The Department of Obstetrics and Gynaecology was commissioned in January 1987. At present there are five full-time faculty members working in the department. The out-patient clinics are busy; patient volume and clinical workload is gradually increasing.

At present we deliver 1800 patients and perform 1200 gynaecological operations per year. Facilities are available for fetal monitoring, ultrasound, CT scanning, urodynamics, gynaecological endoscopy and colposcopy.

Undergraduate and postgraduate teaching programmes are in place. There is a structured Residency Training Programme which is accredited by the College of Physicians and Surgeons of Pakistan and Royal College of Obstetricians and Gynaecologists.

We are currently seeking candidates for the following positions:

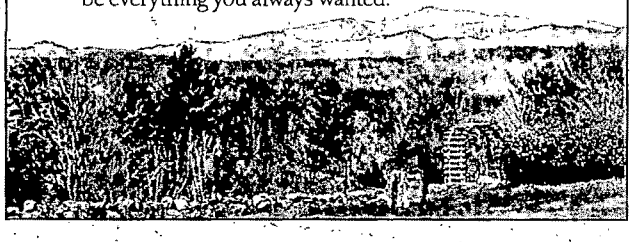
VISITING PROFESSOR — OBSTETRICS AND GYNAECOLOGY

Candidates applying for this position should be senior academic persons who would be interested in practicing, teaching and training Obstetrics and Gynaecology in a developing university. This post will be suitable for a sabbatical assignment.

ASSOCIATE PROFESSOR — OBSTETRICS AND GYNAECOLOGY

Candidates applying for this position are required to have completed their postgraduate training in the related field, with specialty certification, and must have a minimum of 6 years of subsequent clinical and academic experience.

Salary and benefits will be offered commensurate with qualifications, experience and level of responsibility. If you are seeking professional growth and an excellent work environment, please send your detailed résumé, bibliography and names of at least three referees familiar with recent work history to the **Personnel Manager**, The Aga Khan University, P.O. Box 3500, Stadium Road, Karachi-74800, Pakistan.



This established physician practice is offering an excellent opportunity for a BC/BE obstetrician. We're located in beautiful Southeastern New Hampshire, where you'll discover the ideal lifestyle. The location offers proximity to mountains, lakes and seacoast, plus a wealth of cultural attractions. It all adds up to a very healthy family environment.

We're offering a competitive salary, and occurrence malpractice premiums are fully paid. What's more, there's an ownership opportunity after the initial employment period. The position will be available by July, 1992 or earlier.

This position has a lot to offer. In a state that has everything.

The practice is affiliated with a 330-bed hospital with a Level II Nursery in one of scenic New England's fastest-growing areas, just one hour from Boston.

Reply with CV to: Department of Physician Services, Catholic Medical Center, 100 McGregor Street, Manchester, NH 03102. (603) 626-2879. This could be everything you always wanted.

SHOCK YOUR FAMILY & FRIENDS! Tell them you're looking at practicing in eastern North Dakcta or western Minnesota! Our countrypolitan lifestyle includes commutes of up to 9 minutes, 6-car traffic jams, unlocked doors, exceptional schools, bagging the limit in fish and game or just dangling your feet off the dock. The Dakota Clinic is a 154-person multispecialty group looking for OB/GYN physicians. Specific sites include Fargo and Jamestown, North Dakota, as well as Detroit Lakes or Park Rapids, Minnesota. Excellent salary and benefits with stockholder opportunity after two years. There are minimal buy-in requirements. To receive our video and community practice information kit, call Dick Reis at 1-800-342-4926, or write: **Dick Reis, Manager, Recruiting, Dakota Clinic, Ltd., 1702 South University Drive, Fargo, ND 58103.**

FACULTY POSITION UNIVERSITY OF UTAH

GENERAL OBSTETRICS AND GYNECOLOGY

The Department of Obstetrics and Gynecology at the University of Utah School of Medicine is seeking a faculty member for the General Obstetrics and Gynecology Division at the Instructor or Assistant Professor level. Qualification include Board Certification or an active candidates for certification by the American Board of Obstetrics and Gynecology, demonstrated ability and interest in teaching, research and patient care. Interest in routine obstetrics. If interested, please send curriculum vitae and bibliography to:

James R. Scott, M.D.
Professor and Chairman
Department of Obstetrics and Gynecology
University of Utah School of Medicine
50 North Medical Drive
Salt Lake City, Utah 84132

Applications must be postmarked by May 1, 1992. Applications received after that deadline may be considered if no qualified applications have been received by that time. The University of Utah is an Equal Opportunity Affirmative Action Employer.

The Osler Institute
Obstetrics and Gynecology Review Course

March 23-28 – San Francisco June 8-13 – Pittsburgh
October 5-10 – Nashville †Nov. 30-Dec. 5 – Chicago

Your course for exams with practice tests and case-list reviews

OBJECTIVES
- Increase basic knowledge and clinical skills in ob-gyn
- Assist residents and fellows to organize their study
- Prepare candidates to take their examinations
- Provide practicing gynecologists with an update

METHODS
- HOME STUDY MATERIALS with questions and answers
- SEMINAR with projection slides and lecture-note syllabus
- LABORATORY with microscope and glass slides
- PRACTICE EXAMS for your orals

†Plus extra mock oral days December 6-8.

*"The faculty was outstanding. The most pleasant thing was learning a tremendous amount, not only from world-famous authorities, but from people who are relatively unknown as well."**

*"The course was extremely helpful to me."**

COURSES: Fall courses are more clinically oriented. The course includes lectures with syllabus as well as an opportunity for you to buy an unlimited number of 25-minute, one-on-one sessions with faculty to review your case lists or perform mock oral exams. The optional extra days, Dec. 6-8, include a pathology laboratory session, one mock oral exam and observation of seven or more hours of other exams. Past participants recommend repeating the course for half price immediately before exams.

*"Accommodations were comfortable...."**

LOCATION: The San Francisco course will be held at the Holiday Inn Crowne Plaza at the San Francisco International Airport. The Pittsburgh course will be held at the Royce Airport Hotel at the Pittsburgh Airport.

*"...and those little extras...."**

DISCOUNT AIR FARES: Please call toll-free (800) 548-8185 for group discounts.

*"...the most education for the money."**

FEES FOR CATEGORY 1 HOURS:
- Practicing Gynecologist: $780
- Resident or Fellow: $520
- Repeating course within 2 years: $390
- Optional extra days, December 6-8 (per day fee): $180
- **Add 10% within 10 days of the course.**
- Attendees not in course hotel add $20/day.
- A deposit of $50 will reserve your position.

*"...home study material was extremely helpful."**

ACCREDITATION: Jointly sponsored by Penn State's College of Medicine at The Milton S. Hershey Medical Center. Penn State is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to sponsor continuing medical education for physicians.

CREDIT: Penn State designates this continuing medical education activity for **60 credit hours in Category 1** of the Physician's Recognition Award of the American Medical Association.

*"...remarkably complete and pleasant."**

21- and 28-day regimens

ORTHO-NOVUM 777 Tablets

TRADE MARK

norethindrone/ethinyl estradiol

Each white tablet contains 0.5 mg norethindrone and 0.035 mg ethinyl estradiol. Each light peach tablet contains 0.75 mg norethindrone and 0.035 mg ethinyl estradiol. Each peach tablet contains 1 mg norethindrone and 0.035 mg ethinyl estradiol. Each green tablet in 28-day regimen contains inert ingredients.

IMPORTANT NOTE—This information is a BRIEF SUMMARY of the complete prescribing information provided with the product and therefore should not be used as the basis for prescribing the product. This summary was prepared by deleting from the complete prescribing information certain text, tables and references. The physician should be thoroughly familiar with the complete prescribing information before prescribing the product.

INDICATIONS AND USAGE: PREVENTION OF PREGNANCY.

CONTRAINDICATIONS: Oral contraceptives should not be used in women who currently have the following conditions: 1. Thrombophlebitis or thromboembolic disorders. 2. A past history of deep vein thrombophlebitis or thromboembolic disorders. 3. Cerebral vascular or coronary artery disease. 4. Known or suspected carcinoma of the breast. 5. Carcinoma of the endometrium or other known or suspected estrogen-dependent neoplasia. 6. Undiagnosed abnormal genital bleeding. 7. Cholestatic jaundice of pregnancy or jaundice with prior pill use. 8. Hepatic adenomas or carcinomas. 9. Known or suspected pregnancy.

WARNINGS

Cigarette smoking increases the risk of serious cardiovascular side effects from oral contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia, and gallbladder disease, although the risk of serious morbidity or mortality is very small in healthy women without underlying risk factors. The risk of morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemias, obesity and diabetes. Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks. The information contained in this brief summary is principally based on studies carried out in patients who used oral contraceptives with higher formulations of estrogens and progestogens than those in common use today. The effect of long term use of the oral contraceptives with lower formulations of both estrogens and progestogens remains to be determined. Throughout this brief summary epidemiological studies reported are of two types: retrospective or case control studies and prospective or cohort studies. Case control studies provide a measure of the relative risk of a disease, namely a *ratio* of the incidence of a disease among oral contraceptive users to that among nonusers. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide a measure of attributable risk, which is the *difference* in the incidence of disease between oral contraceptive users and nonusers. The attributable risk does provide information about the actual occurrence of a disease in the population. For further information, the reader is referred to a text on epidemiological methods. 1. THROMBOEMBOLIC DISORDERS AND OTHER VASCULAR PROBLEMS. a. Myocardial Infarction. An increased risk of myocardial infarction has been associated with oral contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary artery disease such as hypertension, hypercholesterolemia, morbid obesity, and diabetes. The relative risk of heart attack for current oral contraceptive users has been estimated to be two to six. The risk is very low under the age of 30. Smoking in combination with oral contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women in their mid-thirties or older with smoking accounting for the majority of excess cases. Mortality rates associated with circulatory disease have been shown to increase substantially in smokers, especially in those 35 years of age and older among women who use oral contraceptives. Oral contraceptives may compound the effects of well-known risk factors, such as hypertension, diabetes, hyperlipidemias, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and cause glucose intolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see section 9 in WARNINGS). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors. b. Thromboembolism. An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to non-users to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. Cohort studies have shown the relative risk to be somewhat lower, about 3 for new cases and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease associated with oral contraceptives is not related to length of use and disappears after pill use is stopped. A two- to four-fold increase in relative risk of post-operative thromboembolic complications has been reported with the use of oral contraceptives. The relative risk of venous thrombosis in women who have predisposing conditions is twice that of women without such medical conditions. If feasible, oral contraceptives should be discontinued at least four weeks prior to and for two weeks after elective surgery of a type associated with an increase in risk of thromboembolism and during and following prolonged immobilization. Since the immediate postpartum period is also associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than four weeks after delivery in women who elect not to breast feed. c. Cerebrovascular diseases. Oral contraceptives have been shown to increase both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes), although, in general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and non-users, for both types of strokes, and smoking interacted to increase the risk of stroke. In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for non-smokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 7.6 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk is also greater in older women. d. Dose-related risk of vascular disease from oral contraceptives. A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high density lipoproteins (HDL) has been reported with many progestational agents. A decline in serum high density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the activity of the progestogen used in the contraceptive. The activity and amount of both hormones should be considered in the choice of an oral contraceptive. Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral contraceptive agents should be started on preparations containing 0.035 mg or less of estrogen. e. Persistence of risk of vascular disease. There are two studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40-49 years who had used oral contraceptives for five or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. However, both studies were performed with oral contraceptive formulations containing 50 micrograms or higher of estrogens. 2. ESTIMATES OF MORTALITY FROM CONTRACEPTIVE USE. One study gathered data from a variety of sources which have estimated the mortality rate associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is low and below that associated with childbirth. However, smokers 35 and older and non-smokers 40 and older who use oral contraceptives have a significant increase in mortality higher than those using other methods of birth control. These facts must be weighed in conjunction with failure rates for other methods and the risk associated with subsequent pregnancy. 3. CARCINOMA OF THE REPRODUCTIVE ORGANS. Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. While there are conflicting reports most studies suggest that use of oral contraceptives is not associated with an overall increase in the risk of developing breast cancer. Some studies have reported an increased relative risk of developing breast cancer, particularly at a younger age. This increased relative risk appears to be related to duration of use. Some studies suggest that oral contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors. 4. HEPATIC NEOPLASIA. Benign hepatic adenomas are associated with oral contraceptive use, although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases/100,000 for users, a risk that increases after four or more years of use especially with oral contraceptives of higher dose. Rupture of benign, hepatic adenomas may cause death through intra-abdominal hemorrhage. Studies from Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral contraceptive users. However, these cancers are rare in the U.S. and the attributable risk (the excess incidence) of liver cancers in oral contraceptive users approaches less than one per million users. 5. OCULAR LESIONS. There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia, papilledema, or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately. 6. ORAL CONTRACEPTIVE USE BEFORE OR DURING EARLY PREGNANCY. Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. The majority of recent studies also do not indicate a teratogenic effect, particularly in so far as cardiac anomalies and limb reduction defects are concerned, when taken inadvertently during early pregnancy. The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion. It is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing oral contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral contraceptive use should be discontinued until pregnancy is ruled out. 7. GALLBLADDER DISEASE. Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral contraceptive users may be minimal. The recent findings of minimal risk may be related to the use of oral contraceptive formulations containing lower hormonal doses of estrogens and progestogens. 8. CARBOHYDRATE AND LIPID METABOLIC EFFECTS. Oral contraceptives have been shown to cause a decrease in glucose tolerance in a significant percentage of users. This effect has been shown to be directly related to estrogen dose. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the non-diabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects prediabetic and diabetic women in particular should be carefully monitored while taking oral contraceptives. A small proportion of women will have persistent hypertriglyceridemia while on the pill. As discussed earlier (see WARNINGS 1a and 1d), changes in serum triglycerides and lipoprotein levels have been reported in oral contraceptive users. 9. ELEVATED BLOOD PRESSURE. An increase in blood pressure has been reported in women taking oral contraceptives, and this increase is more likely in older oral contraceptive users and with extended duration of use. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing progestational activity. Women with a history of hypertension or hypertension-related diseases, or renal disease, should be encouraged to use another method of contraception. If women elect to use oral contraceptives, they should be monitored closely and if significant elevation of blood pressure occurs, oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives, and there is no difference in the occurrence of hypertension between former and never users. 10. HEADACHE. The onset or exacerbation of migraine or development of headache with a new pattern which is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause. 11. BLEEDING IRREGULARITIES. Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first three months of use. Non-hormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out. Some women may encounter post-pill amenorrhea or oligomenorrhea, especially when such a condition was preexistent. 12. ECTOPIC PREGNANCY. Ectopic as well as intrauterine pregnancy may occur in contraceptive failures. **PRECAUTIONS:** 1. PHYSICAL EXAMINATION AND FOLLOW UP. A complete medical history and physical examination should be taken prior to the initiation or reinstitution of oral contraceptives and at least annually during use of oral contraceptives. These physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, including cervical cytology, and relevant laboratory tests. In case of undiagnosed persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be conducted to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care. 2. LIPID DISORDERS. Women who are being treated for hyperlipidemias should be followed closely if they elect to use oral contraceptives. Some progestogens may elevate LDL levels and may render the control of hyperlipidemias more difficult. 3. LIVER FUNCTION. If jaundice develops in any woman receiving such drugs, the medication should be discontinued. Steroid hormones may be poorly metabolized in patients with impaired liver function. 4. FLUID RETENTION. Oral contraceptives may cause some degree of fluid retention. They should be prescribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention. 5. EMOTIONAL DISORDERS. Women with a history of depression should be carefully observed and the drug discontinued if depression recurs to a serious degree. 6. CONTACT LENSES. Contact lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist. 7. DRUG INTERACTIONS. Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar association, though less marked, has been suggested with barbiturates, phenylbutazone, phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines. 8. INTERACTIONS WITH LABORATORY TESTS. Certain endocrine and liver function tests and blood components may be affected by oral contraceptives: a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3, increased norepinephrine-induced platelet aggregability. b. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radio-immunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG, free T4 concentration is unaltered. c. Other binding proteins may be elevated in serum. d. Sex-binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged. e. Triglycerides may be increased. f. Glucose tolerance may be decreased. g. Serum folate levels may be depressed by oral contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives. 9. CARCINOGENESIS. See WARNINGS section. 10. PREGNANCY. Pregnancy Category X. See CONTRAINDICATIONS and WARNINGS sections. 11. NURSING MOTHERS. Small amounts of oral contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child. **INFORMATION FOR THE PATIENT: See Patient Package Insert.**

ADVERSE REACTIONS: An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see WARNINGS section). Thrombophlebitis and venous thrombosis with or without embolism. Arterial thromboembolism. Pulmonary embolism. Myocardial infarction. Cerebral hemorrhage. Cerebral thrombosis. Hypertension. Gallbladder disease. Hepatic adenomas or benign liver tumors. The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug-related: Nausea. Vomiting. Gastrointestinal symptoms (such as abdominal cramps and bloating). Breakthrough bleeding. Spotting. Change in menstrual flow. Amenorrhea. Temporary infertility after discontinuation of treatment. Edema. Melasma which may persist. Breast changes: tenderness, enlargement, secretion. Change in weight (increase or decrease). Change in cervical erosion and secretion. Diminution in lactation when given immediately postpartum. Cholestatic jaundice. Migraine. Rash (allergic). Mental depression. Reduced tolerance to carbohydrates. Vaginal candidiasis. Change in corneal curvature (steepening). Intolerance to contact lenses. The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted. Pre-menstrual syndrome. Cataracts. Changes in appetite. Cystitis-like syndrome. Headache. Nervousness. Dizziness. Hirsutism. Loss of scalp hair. Erythema multiform, Erythema nodosum. Hemorrhagic eruption. Vaginitis. Porphyria. Impaired renal function. Hemolytic uremic syndrome. Acne. Changes in libido. Colitis.

OVERDOSAGE: Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea and withdrawal bleeding may occur in females.

Artist's enhancement of scanning electron microscopy: *C albicans* 24 hours posttreatment with butoconazole nitrate.*

When you diagnose vulvovaginal candidiasis (VVC)

FEMSTAT® Prefill (butoconazole nitrate) Vaginal Cream 2% is clinically effective against a broad spectrum of important pathogens, including *Candida albicans* and other *Candida* species, such as *C tropicalis.*

Please See Us at ACOG, Booth #549.

Rx

Artist's enhancement of scanning electron microscopy: *C albicans* one week posttreatment with butoconazole nitrate.*

Prescribe the efficacy of 3-day therapy†

FEMSTAT achieves a microbiological cure rate of 95% with the original 3-day therapy[1] that is not confirmed to be associated with flu-like symptoms. The most common complaint with the use of FEMSTAT in clinical trials was vulvar/vaginal burning (2.3%).

FEMSTAT® PREFILL

(butoconazole nitrate) VAGINAL CREAM 2%

3-day Rx control of VVC

FEMSTAT® PREFILL

(butoconazole nitrate) VAGINAL CREAM 2%

BRIEF SUMMARY

INDICATIONS: FEMSTAT® (butoconazole nitrate) vaginal cream 2% is indicated for local treatment of vulvovaginal mycotic infections caused by Candida species. Confirm the diagnosis by KOH smears and/or cultures. FEMSTAT can be used with oral contraceptives and antibiotics. It is effective in non-pregnant women and during the second and third trimesters of pregnancy.

CONTRAINDICATIONS: FEMSTAT is contraindicated in patients hypersensitive to any of the ingredients.

PRECAUTIONS: General: If clinical symptoms persist, repeat microbiological tests to rule out other pathogens and confirm the diagnosis. Discontinue drug if sensitization or irritation occurs.

Information for the Patient: Do not discontinue prematurely during menstruation or because of symptomatic relief.

Carcinogenesis: Animal studies have not been done.

Mutagenesis: Mutagenicity studies were negative.

Impairment of Fertility: Animal studies showed no impairment of fertility.

Pregnancy Category C: Adverse effects were noted in animals treated with high oral doses. No studies were done in women during first trimester. Patients in the second or third trimester have shown no adverse effects attributable to the drug.

Nursing Mothers: Use with caution.

Pediatric Use: Safety and efficacy have not been established.

ADVERSE REACTIONS: Vulvar/vaginal burning in 2.3% of patients, vulvar itching in 0.9%, discharge, soreness, swelling, itching of fingers each in 0.2%. Complaints caused 1.6% to discontinue drug.

DOSAGE AND ADMINISTRATION: Non-pregnant Patients: The recommended dose is one applicatorful of cream (approximately 5 grams) intravaginally at bedtime for three days. Treatment can be extended for an additional three days if necessary.

Pregnant Patients (second and third trimesters only): The recommended dose is one applicatorful of cream (approximately 5 grams) intravaginally at bedtime for six days.

CAUTION:
Federal law prohibits dispensing without prescription.

Mosby Year Book

Provide vital information to those who need it most . . .

with article reprints from Mosby-Year Book periodicals

Article reprints are your best means of distributing the information published in Mosby-Year Book's medical, dental, and nursing periodicals. These papers will enhance the value of your information programs.

Not just for authors, reprints are an effective tool for health care professionals, sales and marketing staffs, and advertisers.

Use reprints to:

- Train and educate your sales and marketing staff
- Support your seminar topic
- Inform your health care staff of new developments
- Reach your product users with vital information

Article reprints . . . another valuable service from Mosby-Year Book.

Orders (minimum of 100 copies) of all previous and future articles in Mosby-Year Book periodicals are available from the Publisher.

For more information, contact:

Contraception PLUS health benefits for the woman over 35

Because she needs an effective contraceptive that may provide specific noncontraceptive health benefits.*

TRI-LEVLEN®

Levonorgestrel and ethinyl estradiol tablets—Triphasic regimen

ENHANCING YOUR PERCEPTION OF ORAL CONTRACEPTION

*Serious as well as minor side effects have been reported with use of all oral contraceptives. The physician should remain alert to the earliest symptoms of serious disease and discontinue oral contraceptive therapy when appropriate. Please see full prescribing information, a brief summary of which follows.

BERLEX Dedicated to innovation in OB/GYN medicine

914300071

TRI·LEVLEN® Levonorgestrel and ethinyl estradiol tablets–Triphasic regimen

TRI-LEVLEN® 28 TRI-LEVLEN® 21

BRIEF SUMMARY

Tri-Levlen®—6 brown tablets, each containing 0.050 mg of levonorgestrel (d(-)-13 beta-ethyl-17-alpha-ethinyl-17-beta-hydroxygon-4-en-3-one), a totally synthetic progestogen, and 0.030 mg of ethinyl estradiol (19-nor-17α-pregna-1,3,5(10)-trien-20-yne-3, 17-diol); 5 white tablets, each containing 0.075 mg levonorgestrel and 0.040 mg ethinyl estradiol; 10 light-yellow tablets, each containing 0.125 mg levonorgestrel and 0.030 mg ethinyl estradiol (7 light-green tablets containing inert ingredients are included in the 28-day triphasic regimen).

Indications and Usage

Oral contraceptives are indicated for the prevention of pregnancy in women who elect to use this product as a method of contraception.

Contraindications

Oral contraceptives should not be used in women with any of the following conditions: thrombophlebitis or thromboembolic disorders, a past history of deep-vein thrombophlebitis or thromboembolic disorders, cerebral-vascular or coronary-artery disease, known or suspected carcinoma of the breast, carcinoma of the endometrium or other known or suspected estrogen-dependant neoplasia, undiagnosed abnormal genital bleeding, cholestatic jaundice of pregnancy or jaundice with prior pill use, hepatic adenomas or carcinomas, known or suspected pregnancy.

Warnings

Cigarette smoking increases the risk of serious cardiovascular side effects from oral-contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia, gallbladder disease, and hypertension, although the risk of serious morbidity or mortality is very small in healthy women without underlying risk factors. The risk of morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemias, obesity and diabetes. Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks. The information contained in this package insert is principally based on studies carried out in patients who used oral contraceptives with higher formulations of estrogens and progestogens than those in common use today. The effect of long-term use of the oral contraceptives with lower formulations of both estrogens and progestogens remains to be determined. Throughout this labeling, epidemiological studies reported are of two types: retrospective or case control studies and prospective or cohort studies. Case control studies provide a measure of the relative risk of disease, namely, a ratio of the incidence of a disease among oral-contraceptive users to that among nonusers. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide a measure of attributable risk, which is the difference in the incidence of disease between oral-contraceptive users and nonusers. The attributable risk does provide information about the actual occurrence of a disease in the population. For further information, the reader is referred to a text on epidemiological methods.

1. *Thromboembolic Disorders and Other Vascular Problems*

a. *Myocardial Infarction.* An increased risk of myocardial infarction has been attributed to oral-contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary-artery disease such as hypertension, hypercholesterolemia, morbid obesity, and diabetes. The relative risk of heart attack for current oral-contraceptive users has been estimated to be two to six. The risk is very low under the age of 30. Smoking in combination with oral-contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women in their mid-thirties or older with smoking accounting for the majority of excess cases. Mortality rates associated with circulatory disease have been shown to increase substantially in smokers over the age of 35 and non-smokers over the age of 40 among women who use oral contraceptives. Oral contraceptives may compound the effects of well-known risk factors, such as hypertension, diabetes, hyperlipidemias, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and cause glucose intolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see section 9 in "Warnings"). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors.

b. *Thromboembolism.* An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to nonusers to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep-vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. Cohort studies have shown the relative risk to be somewhat lower, about 3 for new cases and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease due to oral contraceptives is not related to length of use and disappears after pill use is stopped. A two-to four-fold increase in relative risk of postoperative thromboembolic complications has been reported with the use of oral contraceptives. The relative risk of venous thrombosis in women who have predisposing conditions is twice that of women without such medical conditions. If feasible, oral contraceptives should be discontinued at least four weeks prior to and for two weeks after elective surgery of a type associated with an increase in risk of thromboembolism and during and following prolonged immobilization. Since the immediate post partum period is also associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than four to six weeks after delivery in women who elect not to breast-feed, or a midtrimester pregnancy termination.

c. *Cerebrovascular diseases.* Oral contraceptives have been shown to increase both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes), although, in general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and nonusers, for both types of strokes, while smoking interacted to increase the risk for hemorrhagic strokes. In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for nonsmokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 7.6 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk is also greater in older women.

d. *Dose-related risk of vascular disease from oral contraceptives.* A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high-density lipoproteins (HDL) has been reported with many progestational agents. A decline in serum high-density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the nature and absolute amount of progestogen used in the contraceptive. The amount of both hormones should be considered in the choice of an oral contraceptive. Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral-contraceptive agents should be started on preparations containing less than 50 mcg of estrogen.

e. *Persistence of risk of vascular disease.* There are two studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40-49 years who had used oral contraceptives for five or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. However, both studies were performed with oral-contraceptive formulations containing 50 micrograms or higher of estrogens.

2. *Estimates of Mortality from Contraceptive Use.* One study gathered data from a variety of sources which have estimated the mortality rate associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral-contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is less than that associated with childbirth. The observation of a possible increase in risk of mortality with age for oral-contraceptive users is based on data gathered in the 1970's–but not reported until 1983. However, current clinical practice involves the use of lower estrogen dose formulations combined with careful restriction of oral-contraceptive use to women who do not have the various risk factors listed in this labeling. Because of these changes in practice and, also, because of some limited new data which suggest that the risk of cardiovascular disease with the use of oral contraceptives may now be less than previously observed, the Fertility and Maternal Health Drugs Advisory Committee was asked to review the topic in 1989. The Committee concluded that although cardiovascular-disease risks may be increased with oral-contraceptive use after age 40 in healthy nonsmoking women (even with the newer low-dose formulations), there are greater potential health risks associated with pregnancy in older women and with the alternative surgical and medical procedures which may be necessary if such women do not have access to effective and acceptable means of contraception. Therefore, the Committee recommended that the benefits of oral-contraceptive use by healthy nonsmoking women over 40 may outweigh the possible risks. Of course, older women, as all women who take oral contraceptives, should take the lowest possible dose formulation that is effective.

3. *Carcinoma of the Reproductive Organs.* Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. The overwhelming evidence in the literature suggests that use of oral contraceptives is not associated with an increase in the risk of developing breast cancer, regardless of the age and parity of first use or with most of the marketed brands and doses. The Cancer and Steroid Hormone (CASH) study also showed no latent effect on the risk of breast cancer for at least a decade following long-term use. A few studies have shown a slightly increased relative risk of developing breast cancer, although the methodology of these studies, which included differences in examination of users and nonusers and differences in age at start of use, has been questioned. Some studies suggest that oral-contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors. In spite of many studies of the relationship between oral-contraceptive use and breast and cervical cancers, a cause-and-effect relationship has not been established.

4. *Hepatic Neoplasia.* Benign hepatic adenomas are associated with oral-contraceptive use, although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases/100,000 for users, a risk that increases after four or more years of use. Rupture of rare, benign, hepatic adenomas may cause death through intra-abdominal hemorrhage. Studies from Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral-contraceptive users. However, these cancers are extremely rare in the U.S. and the attributable risk (the excess incidence) of liver cancers in oral-contraceptive users approaches less than one per million users.

5. *Ocular Lesions.* There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia; papilledema; or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately.

6. *Oral-Contraceptive Use Before or During Early Pregnancy.* Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. Studies also do not suggest a teratogenic effect, particularly insofar as cardiac anomalies and limb-reduction defects are concerned, when taken inadvertently during early pregnancy. The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion. It is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing oral-contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral-contraceptive use should be discontinued if pregnancy is confirmed.

7. *Gallbladder Disease.* Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral-contraceptive users may be minimal. The recent findings of minimal risk may be related to the use of oral-contraceptive formulations containing lower hormonal doses of estrogens and progestogens.

8. *Carbohydrate and Lipid Metabolic Effects.* Oral contraceptives have been shown to cause glucose intolerance in a significant percentage of users. Oral contraceptives containing greater than 75 micrograms of estrogens cause hyperinsulinism, while lower doses of estrogen cause less glucose intolerance. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the nondiabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects, prediabetic and diabetic women should be carefully observed while taking oral contraceptives. A small proportion of women will have persistent hypertriglyceridemia while on the pill. As discussed earlier (see "Warnings" 1a. and 1d.), changes in serum triglycerides and lipoprotein levels have been reported in oral-contraceptive users.

9. *Elevated Blood Pressure.* An increase in blood pressure has been reported in women taking oral contraceptives and this increase is more likely in older oral-contraceptive users and with continued use. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing quantities of progestogens. Women with a history of hypertension or hypertension-related diseases, or renal disease should be encouraged to use another method of contraception. If women with hypertension elect to use oral contraceptives, they should be monitored closely, and if significant elevation of blood pressure occurs, oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives, and there is no difference in the occurrence of hypertension among ever-and never-users.

10. *Headache.* The onset or exacerbation of migraine or development of headache with a new pattern that is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause.

11. *Bleeding Irregularities.* Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first three months of use. The type and dose of progestogen may be important. Nonhormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding, as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out. Some women may encounter post-pill amenorrhea or oligomenorrhea, especially when such a condition was preexistent.

Precautions

1. PHYSICAL EXAMINATION AND FOLLOW UP. A complete medical history and physical examination should be taken prior to the initiation or reinstitution of oral contraceptives and at least annually during use of oral contraceptives. These physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, including cervical cytology, and relevant laboratory tests. In case of undiagnosed, persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be conducted to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care. 2. LIPID DISORDERS. Women who are being treated for hyperlipidemias should be followed closely if they elect to use oral contraceptives. Some progestogens may elevate LDL levels and may render the control of hyperlipidemias more difficult. (See "Warnings" 1d.) 3. LIVER FUNCTION. If jaundice develops in any woman receiving such drugs, the medication should be discontinued. Steroid hormones may be poorly metabolized in patients with impaired liver function. 4. FLUID RETENTION. Oral contraceptives may cause some degree of fluid retention. They should be prescribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention. 5. EMOTIONAL DISORDERS. Patients becoming significantly depressed while taking oral contraceptives should stop the medication and use an alternate method of contraception in an attempt to determine whether the symptom is drug related. Women with a history of depression should be carefully observed and the drug discontinued if depression recurs to a serious degree. 6. CONTACT LENSES. Contact-lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist. 7. DRUG INTERACTIONS. Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar association, though less marked, has been suggested with barbiturates, phenylbutazone, phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines. 8. INTERACTIONS WITH LABORATORY TESTS. Certain endocrine-and liver-function tests and blood components may be affected by oral contraceptives: a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3; increased norepinephrine-induced platelet aggregability. b. Increased thyroid-binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radioimmunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG; free T4 concentration is unaltered. c. Other binding proteins may be elevated in serum. d. Sex-binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged. e. Triglycerides may be increased. f. Glucose tolerance may be decreased. g. Serum folate levels may be depressed by oral-contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives. 9. CARCINOGENESIS. See "Warnings" section. 10. PREGNANCY. Pregnancy Category X. See "Contraindications" and "Warnings" sections. 11. NURSING MOTHERS. Small amounts of oral-contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child.

Information for the Patient

See Patient Labeling.

Adverse Reactions

An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see "Warnings" section): thrombophlebitis, arterial thromboembolism, pulmonary embolism, myocardial infarction, cerebral hemorrhage, cerebral thrombosis, hypertension, gallbladder disease, hepatic adenomas or benign liver tumors.

There is evidence of an association between the following conditions and the use of oral contraceptives, although additional confirmatory studies are needed: mesenteric thrombosis, retinal thrombosis.

The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug related: nausea; vomiting; gastrointestinal symptoms (such as abdominal cramps and bloating); breakthrough bleeding; spotting; change in menstrual flow; amenorrhea; temporary infertility after discontinuation of treatment; edema; melasma which may persist; breast changes: tenderness, enlargement, secretion; change in weight (increase or decrease); change in cervical erosion and secretion; diminution in lactation when given immediately postpartum; cholestatic jaundice; migraine; rash (allergic); mental depression; reduced tolerance to carbohydrates; vaginal candidiasis; change in corneal curvature (steepening); intolerance to contact lenses.

The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted: congenital anomalies, premenstrual syndrome, cataracts, optic neuritis, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, hirsutism, loss of scalp hair, erythema multiforme, cerebral-vascular disease with mitral valve prolapse, lupus-like syndromes, erythema nodosum, hemorrhagic eruption, vaginitis, porphyria, impaired renal function, hemolytic uremic syndrome, Budd-Chiari syndrome, acne, changes in libido, colitis, sickle-cell disease.

Overdosage

Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea, and withdrawal bleeding may occur in females.

Noncontraceptive Health Benefits

The following noncontraceptive health benefits related to the use of oral contraceptives are supported by epidemiological studies which largely utilized oral-contraceptive formulations containing doses exceeding 0.035 mg of ethinyl estradiol or 0.05 mg of mestranol.

Effects on menses: increased menstrual cycle regularity, decreased blood loss and decreased incidence of iron-deficiency anemia, decreased incidence of dysmenorrhea.

Effects related to inhibition of ovulation: decreased incidence of functional ovarian cysts, decreased incidence of ectopic pregnancies.

Effects from long-term use: decreased incidence of fibroadenomas and fibrocystic disease of the breast, decreased incidence of acute pelvic inflammatory disease, decreased incidence of endometrial cancer, decreased incidence of ovarian cancer.

Dosage and Administration

To achieve maximum contraceptive effectiveness, TRI-LEVLEN® tablets (Levonorgestrel and Ethinyl Estradiol Tablets—Triphasic Regimen) must be taken exactly as directed and at intervals not exceeding 24 hours.

For full details on dosage and administration see prescribing information in package insert. 60627-0 5/90

Evidence of embryo- and trophoblast-toxic cellular immune response(s) in women with recurrent spontaneous abortion 1044
Joseph A. Hill, MD, Katalin Polgar, PhD, Bernard L. Harlow, PhD, and Deborah J. Anderson, PhD
Boston, Massachusetts

A potential new mechanism of recurrent abortion may involve the secretion of interferon gamma or other cytokines produced by maternal leukocytes in response to activation by either sperm or trophoblast antigens.

Functional analysis of a mutant estrogen receptor isolated from T47Dco breast cancer cells 1053
Kimberly K. Leslie, MD, Diane M. Tasset, PhD, and Kathryn B. Horwitz, PhD
Denver, Colorado

A deoxyribonucleic acid–binding domain mutant estrogen receptor has been isolated and characterized from T47Dco human breast cancer cells that may have low levels of constitutive deoxyribonucleic acid–binding capabilities, thus contributing to the estrogen-resistant phenotype of these cells.

CEFOTAN® IM/IV

(cefotetan disodium)

Available in 1-gram and 2-gram vials

For Intravenous or Intramuscular Use
PLEASE SEE FULL PRESCRIBING INFORMATION FOR A COMPLETE DESCRIPTION.
A BRIEF SUMMARY FOLLOWS.

INDICATIONS AND USAGE
TREATMENT

CEFOTAN is indicated for the therapeutic treatment of the following infections when caused by susceptible strains of the designated organisms:

Urinary Tract Infections caused by *E. coli, Klebsiella* species (including *K. pneumoniae*), *Proteus mirabilis,* and *Proteus* sp (which may include the organisms now called *Proteus vulgaris, Providencia rettgeri,* and *Morganella morganii*).

Lower Respiratory Tract Infections caused by *Streptococcus pneumoniae* (formerly *D. pneumoniae*), *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Haemophilus influenzae* (including ampicillin-resistant strains), *Klebsiella* species (including *K. pneumoniae*), *E. coli, Proteus mirabilis,* and *Serratia marcescens**.

Skin and Skin Structure Infections due to *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis, Streptococcus pyogenes, Streptococcus* species (excluding enterococci), *Escherichia coli, Klebsiella pneumoniae, Peptococcus niger**, *Peptostreptococcus* species.

Gynecologic Infections caused by *Staphylococcus aureus* (including penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis, Streptococcus* species (excluding enterococci), *Streptococcus agalactiae, E. coli, Proteus mirabilis, Neisseria gonorrhoeae,* Bacteroides species (excluding *B. distasonis, B. ovatus, B. thetaiotaomicron*), *Fusobacterium* species*, and gram-positive anaerobic cocci (including *Peptococcus niger* and *Peptostreptococcus* species).

Cefotetan, like other cephalosporins, has no activity against *Chlamydia trachomatis.* Therefore, when cephalosporins are used in the treatment of pelvic inflammatory disease, and *C. trachomatis* is one of the suspected pathogens, appropriate antichlamydial coverage should be added.

Intra-abdominal Infections caused by *E. coli, Klebsiella* species (including *K. pneumoniae*), *Streptococcus* species (excluding enterococci), *Bacteroides* species (excluding *B. distasonis, B. ovatus, B. thetaiotaomicron*) and *Clostridium* species*.

Bone and Joint Infections caused by *Staphylococcus aureus**.

*Efficacy for this organism in this organ system was studied in fewer than ten infections.

Specimens for bacteriological examination should be obtained in order to isolate and identify causative organisms and to determine their susceptibilities to cefotetan. Therapy may be instituted before results of susceptibility studies are known; however, once these results become available, the antibiotic treatment should be adjusted accordingly.

In cases of confirmed or suspected gram-positive or gram-negative sepsis or in patients with other serious infections in which the causative organism has not been identified, it is possible to use CEFOTAN concomitantly with an aminoglycoside. Cefotetan combinations with aminoglycosides have been shown to be synergistic *in vitro* against many Enterobacteriaceae and also some other gram-negative bacteria. The dosage recommended in the labeling of both antibiotics may be given and depends on the severity of the infection and the patient's condition.

NOTE: If CEFOTAN and an aminoglycoside are used concomitantly, renal function should be carefully monitored, especially if higher dosages of the aminoglycoside are to be administered or if therapy is prolonged, because of the potential nephrotoxicity and ototoxicity of aminoglycosidic antibiotics. Although, to date, nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

PROPHYLAXIS

The preoperative administration of CEFOTAN may reduce the incidence of certain postoperative infections in patients undergoing surgical procedures that are classified as clean contaminated or potentially contaminated (e.g., cesarean section, abdominal or vaginal hysterectomy, transurethral surgery, biliary tract surgery, and gastrointestinal surgery).

The prophylactic dose of CEFOTAN should be administered 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, CEFOTAN should be administered intravenously after the clamping of the umbilical cord.

If there are signs and symptoms of infection, specimens for culture should be obtained for identification of the causative organism so that appropriate therapeutic measures may be initiated.

CONTRAINDICATIONS

CEFOTAN is contraindicated in patients with known allergy to the cephalosporin group of antibiotics.

WARNINGS

BEFORE THERAPY WITH CEFOTAN IS INSTITUTED, CAREFUL INQUIRY SHOULD BE MADE TO DETERMINE WHETHER THE PATIENT HAS HAD PREVIOUS HYPERSENSITIVITY REACTIONS TO CEFOTETAN DISODIUM, CEPHALOSPORINS, PENICILLINS, OR OTHER DRUGS. IF THIS PRODUCT IS TO BE GIVEN TO PENICILLIN-SENSITIVE PATIENTS, CAUTION SHOULD BE EXERCISED BECAUSE CROSS-HYPERSENSITIVITY AMONG BETA-LACTAM ANTIBIOTICS HAS BEEN CLEARLY DOCUMENTED AND MAY OCCUR IN UP TO 10% OF PATIENTS WITH A HISTORY OF PENICILLIN ALLERGY. IF AN ALLERGIC REACTION TO CEFOTAN OCCURS, DISCONTINUE THE DRUG. SERIOUS ACUTE HYPERSENSITIVITY REACTIONS MAY REQUIRE TREATMENT WITH EPINEPHRINE AND OTHER EMERGENCY MEASURES, INCLUDING OXYGEN, INTRAVENOUS FLUIDS, INTRAVENOUS ANTIHISTAMINES, CORTICOSTEROIDS, PRESSOR AMINES AND AIRWAY MANAGEMENT, AS CLINICALLY INDICATED.

Pseudomembranous colitis has been reported with nearly all antibacterial agents, including cefotetan, and may range from mild to life-threatening. Onset of pseudomembranous colitis symptoms may occur during or after antibiotic treatment or surgical prophylaxis. Therefore, it is important to consider this diagnosis in patients who present with diarrhea subsequent to the administration of antibacterial agents.

Treatment with antibacterial agents alters the normal flora of the colon and may permit overgrowth of clostridia. Studies indicate that a toxin produced by *Clostridium difficile* is a primary cause of "antibiotic-associated colitis."

After the diagnosis of pseudomembranous colitis has been established, therapeutic measures should be initiated. Mild cases of pseudomembranous colitis usually respond to discontinuation of the drug alone. In moderate to severe cases, consideration should be given to management with fluids and electrolytes, protein supplementation, and treatment with an oral antibacterial drug effective against *Clostridium difficile.*

In common with many other broad-spectrum antibiotics, CEFOTAN may be associated with a fall in prothrombin activity and, possibly, subsequent bleeding. Those at increased risk include patients with renal or hepatobiliary impairment or poor nutritional state, the elderly, and patients with cancer. Prothrombin time should be monitored and exogenous vitamin K administered as indicated.

PRECAUTIONS

General: As with other broad-spectrum antibiotics, prolonged use of CEFOTAN may result in overgrowth of nonsusceptible organisms. Careful observation of the patient is essential. If superinfection does occur during therapy, appropriate measures should be taken.

CEFOTAN should be used with caution in individuals with a history of gastrointestinal disease, particularly colitis.

Information for Patients: As with some other cephalosporins, a disulfiram-like reaction characterized by flushing, sweating, headache, and tachycardia may occur when alcohol (beer, wine, etc.) is ingested within 72 hours after CEFOTAN administration. Patients should be cautioned about the ingestion of alcoholic beverages following the administration of CEFOTAN.

Drug Interactions: Although to date nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

Drug/Laboratory Test Interactions: The administration of CEFOTAN may result in a false-positive reaction for glucose in the urine using Clinitest®†, Benedict's solution, or Fehling's solution. It is recommended that glucose tests based on enzymatic glucose oxidase be used.

As with other cephalosporins, high concentrations of cefotetan may interfere with measurement of serum and urine creatinine levels by Jaffe reaction and produce false increases in the levels of creatinine reported.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Although long-term studies in animals have not been performed to evaluate carcinogenic potential, no mutagenic potential of cefotetan was found in standard laboratory tests.

Cefotetan has adverse effects on the testes of prepubertal rats. Subcutaneous administration of 500 mg/kg/day (approximately 8-16 times the usual adult human dose) on days 6-35 of life (thought to be developmentally analogous to late childhood and prepuberty in humans) resulted in reduced testicular weight and seminiferous tubule degeneration in 10 of 10 animals. Affected cells included spermatogonia and spermatocytes; Sertoli and Leydig cells were unaffected. Incidence and severity of lesions were dose-dependent; at 120 mg/kg/day (approximately 2-4 times the usual human dose) only 1 of 10 treated animals was affected, and the degree of degeneration was mild.

Similar lesions have been observed in experiments of comparable design with other methylthiotetrazole-containing antibiotics and impaired fertility has been reported, particularly at high dose levels. No testicular effects were observed in 7-week-old rats treated with up to 1000 mg/kg/day SC for 5 weeks, or in infant dogs (3 weeks old) that received up to 300 mg/kg/day IV for 5 weeks. The relevance of these findings to humans is unknown.

Pregnancy: Teratogenic Effects. Pregnancy Category B: Reproduction studies have been performed in rats and monkeys at doses up to 20 times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to cefotetan. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproductive studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Nursing Mothers: Cefotetan is excreted in human milk in very low concentrations. Caution should be exercised when cefotetan is administered to a nursing woman.

Pediatric Use: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS

In clinical studies, the following adverse effects were considered related to CEFOTAN therapy. Those appearing in italics have been reported during postmarketing experience.

Gastrointestinal symptoms occurred in 1.5% of patients; the most frequent were diarrhea (1 in 80) and nausea (1 in 700); *pseudomembranous colitis.* Onset of pseudomembranous colitis symptoms may occur during or after antibiotic treatment or surgical prophylaxis. (See WARNINGS.)

Hematologic laboratory abnormalities occurred in 1.4% of patients and included eosinophilia (1 in 200), positive direct Coombs' test (1 in 250), and thrombocytosis (1 in 300); *agranulocytosis, hemolytic anemia, leukopenia, thrombocytopenia,* and *prolonged prothrombin time.*

Hepatic enzyme elevations occurred in 1.2% of patients and included a rise in SGPT (1 in 150), SGOT (1 in 300), alkaline phosphatase (1 in 700), and LDH (1 in 700).

Hypersensitivity reactions were reported in 1.2% of patients and included rash (1 in 150) and itching (1 in 700); *anaphylactic reactions.*

Local effects were reported in less than 1.0% of patients and included phlebitis at the site of injection (1 in 300), and discomfort (1 in 500).

Miscellaneous: *Fever*

In addition to the adverse reactions listed above which have been observed in patients treated with cefotetan, the following adverse reactions and altered laboratory tests have been reported for cephalosporin-class antibiotics: urticaria, pruritis, Stevens-Johnson syndrome, erythema multiforme, toxic epidermal necrolysis, vomiting, abdominal pain, colitis, superinfection, vaginitis including vaginal candidiasis, renal dysfunction, toxic nephropathy, hepatic dysfunction including cholestasis, aplastic anemia, hemorrhage, increased BUN, increased creatinine, elevated bilirubin, pancytopenia, and neutropenia.

Several cephalosporins have been implicated in triggering seizures, particularly in patients with renal impairment when the dosage was not reduced (see DOSAGE AND ADMINISTRATION and OVERDOSAGE). If seizures associated with drug therapy occur, the drug should be discontinued. Anticonvulsant therapy can be given if clinically indicated.

DOSAGE AND ADMINISTRATION
TREATMENT

The usual adult dosage is 1 or 2 grams of CEFOTAN administered intravenously or intramuscularly every 12 hours for 5 to 10 days. Proper dosage and route of administration should be determined by the condition of the patient, severity of the infection, and susceptibility of the causative organism.

GENERAL GUIDELINES FOR DOSAGE OF CEFOTAN

Type of Infection	Daily Dose	Frequency and Route
Urinary Tract	1-4 grams	500 mg every 12 hours IV or IM 1 or 2 g every 24 hours IV or IM 1 or 2 g every 12 hours IV or IM
Skin & Skin Structure		
Mild-Moderate[a]	2 grams	2 g every 24 hours IV 1 g every 12 hours IV or IM
Severe	4 grams	2 g every 12 hours IV
Other Sites	2-4 grams	1 or 2 g every 12 hours IV or IM
Severe	4 grams	2 g every 12 hours IV
Life-Threatening	6 grams[b]	3 g every 12 hours IV

[a] *K. pneumoniae* skin and skin structure infections should be treated with 1 or 2 grams every 12 hours IV or IM.

[b] Maximum daily dosage should not exceed 6 grams.

If *C. trachomatis* is a suspected pathogen in gynecologic infections, appropriate antichlamydial coverage should be added, since cefotetan has no activity against this organism.

PROPHYLAXIS

To prevent postoperative infection in clean contaminated or potentially contaminated surgery in adults, the recommended dosage is 1 or 2 g of CEFOTAN administered once, intravenously, 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, the dose should be administered as soon as the umbilical cord is clamped.

IMPAIRED RENAL FUNCTION

When renal function is impaired, a reduced dosage schedule must be employed. See FULL PRESCRIBING INFORMATION for a complete description.

NOTE: Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration whenever solution and container permit.

Leadership qualities of obstetrics and gynecology department chairmen of United States medical schools 1102
G. William Bates, MD, and Dawn W. Blackhurst, MS
Greenville, South Carolina

Having a mentor facilitates the development of skills that are important for chairmen of medical school departments of obstetrics and gynecology.

Human ovarian 17-ketosteroid oxidoreductase: Unique characteristics of the granulosa-luteal cell and stromal enzyme 1117
Robert L. Barbieri, MD
Stony Brook, New York

Human ovarian stromal 17-ketosteroid oxidoreductase resembles the enzyme present in Leydig cells, and the granulosa-luteal cell 17-ketosteroid oxidoreductase resembles the enzyme present in the placenta; in hyperandrogenic women the ovarian stromal 17-ketosteroid oxidoreductase may be overexpressed, contributing to an abnormally increased testosterone production rate.

Anticonvulsant effects of magnesium sulfate on hippocampal seizures: Therapeutic implications in preeclampsia-eclampsia 1127
David B. Cotton, MD, Cynthia A. Janusz, BS, and Robert F. Berman, PhD
Detroit, Michigan

Magnesium sulfate demonstrated central anticonvulsant effects in three animal models of hippocampal seizures.

Comparison of the peritoneal cells elicited by oxidized regenerated cellulose (Interceed) and expanded polytetrafluoroethylene (Gore-Tex Surgical Membrane) in a murine model 1137
A.F. Haney, MD, and Elissa Doty, BA
Durham, North Carolina

In a murine model, oxidized regenerated cellulose (Interceed), but not expanded polytetrafluoroethylene (Gore-Tex Surgical Membrane), elicited a peritoneal cell response suggestive of an acute inflammatory reaction.

Maternal phenylketonuria collaborative study, obstetric aspects and outcome: The first 6 years 1150
Lawrence D. Platt, MD, Richard Koch, MD, Colleen Azen, MS, William B. Hanley, MD, Harvey L. Levy, MD, Reuben Matalon, MD, PhD, Bobbye Rouse, MD, Felix de la Cruz, MD, MPH, and Catherine A. Walla, RN, MA, MN
Bethesda, Maryland, Los Angeles, California, Boston, Massachusetts, Galveston, Texas, Chicago, Illinois, and Toronto, Ontario, Canada

Optimal fetal outcome in hyperphenylalaninemic pregnancies appears to occur when maternal blood phenylalanine levels <10 mg/dl are achieved by 8 to 10 weeks' gestation and maintained throughout pregnancy.

Postmenopausal steroid replacement with micronized dehydroepiandrosterone: Preliminary oral bioavailability and dose proportionality studies 1163

John E. Buster, MD, Peter R. Casson, MD, Arthur B. Straughn, PharmD, Debra Dale, RN, Edward S. Umstot, MS, Neil Chiamori, PhD, and Guy E. Abraham, MD

Memphis, Tennessee, and Santa Monica and Torrance, California

Single doses of oral micronized dehydroepiandrosterone were absorbed efficiently and converted to dehydroepiandrosterone sulfate and testosterone, but not estradiol, in postmenopausal women.

Endothelium-derived relaxing factor and indomethacin-sensitive contracting factor alter arterial contractile responses to thromboxane during pregnancy 1171

Carl P. Weiner, MD, Loren P. Thompson, PhD, Kang-Zhu Liu, MD, and James E. Herrig, BS

Iowa City, Iowa

Vascular smooth-muscle response to thromboxane in vitro is altered by pregnancy.

Lp(a) lipoprotein: Relationship to cardiovascular disease risk factors, exercise, and estrogen 1182

Rogerio A. Lobo, MD, Morris Notelovitz, MD, PhD, Leslie Bernstein, PhD, Farouk Y. Khan, MD, Ronald K. Ross, MD, and Wellington L. Paul, PhD

Los Angeles, California, and Gainesville, Florida

Lp(a) lipoprotein levels were higher in patients with cardiovascular disease but were not influenced by age, sex, or exercise; oral estrogen had a minor effect.

Lipid and apolipoprotein abnormalities in hirsute women. I. The association with insulin resistance 1191

Robert A. Wild, MD, Petar Alaupovic, PhD, and Ivy J. Parker, BS, RN

Oklahoma City, Oklahoma

Gonadotropin-releasing hormone analog was used to remove gonadal sex steroid influence on lipoprotein metabolism in hirsute women to dissect out the independent effects of insulin resistance.

Elevated maternal plasma corticotropin-releasing hormone levels in pregnancies complicated by preterm labor 1198

Wendy B. Warren, MD, Sharon L. Patrick, MD, and Robin S. Goland, MD

New York, New York

Maternal plasma levels of placental corticotropin-releasing hormone are elevated in pregnancies complicated by preterm labor; these elevations may reflect early activation of the placenta in mechanisms leading to preterm labor.

Clinical Articles

Rates and outcomes of planned pregnancy after use of Norplant capsules, Norplant II rods, or levonorgestrel-releasing or copper TCu 380Ag intrauterine contraceptive devices 1208

Irving Sivin, MA, Janet Stern, BS, Soledad Diaz, MD, Margarita Pavéz, RN, Francisco Alvarez, MD, Vivian Brache, BS, Daniel R. Mishell, Jr., MD, Maria Lacarra, RN, Terence McCarthy, MB, BS, Pentti Holma, MD, Philip Darney, MD, Cynthia Klaisle, MSN, Sven-Eric Olsson, MD, and Viveca Odlind, MD

New York, New York, Santiago, Chile, Santo Domingo, Dominican Republic, Los Angeles and San Francisco, California, Singapore, Jyväskylä, Finland, and Uppsala, Sweden

After contraception with levonorgestrel implants or with levonorgestrel-releasing or copper-releasing intrauterine contraceptive devices, pregnancy rates and outcomes were within normal limits.

Progression of diabetic retinopathy in pregnancy: Association with hypertension in pregnancy 1214

Barak Rosenn, MD, Menachem Miodovnik, MD, Jane Khoury, MS, George Kranias, MD, C. Andrew Combs, MD, PhD, Francis Mimouni, MD, Tariq A. Siddiqi, MD, and Matthew J. Lipman, MD

Cincinnati, Ohio

Progression of retinopathy during pregnancy in insulin-dependent diabetes is associated with glycemic control in early pregnancy, chronic hypertension, and pregnancy-induced hypertension.

Prenatal ultrasonographic findings associated with wide clefting of the upper two thirds of the fetal sternum 1219

Paula R. Mahone, MD, David M. Sherer, MD, Carl D'Angio, MD, and James R. Woods, Jr., MD

Rochester, New York

We describe the first report of prenatal ultrasonographic findings associated with wide clefting of the superior two thirds of the fetal sternum.

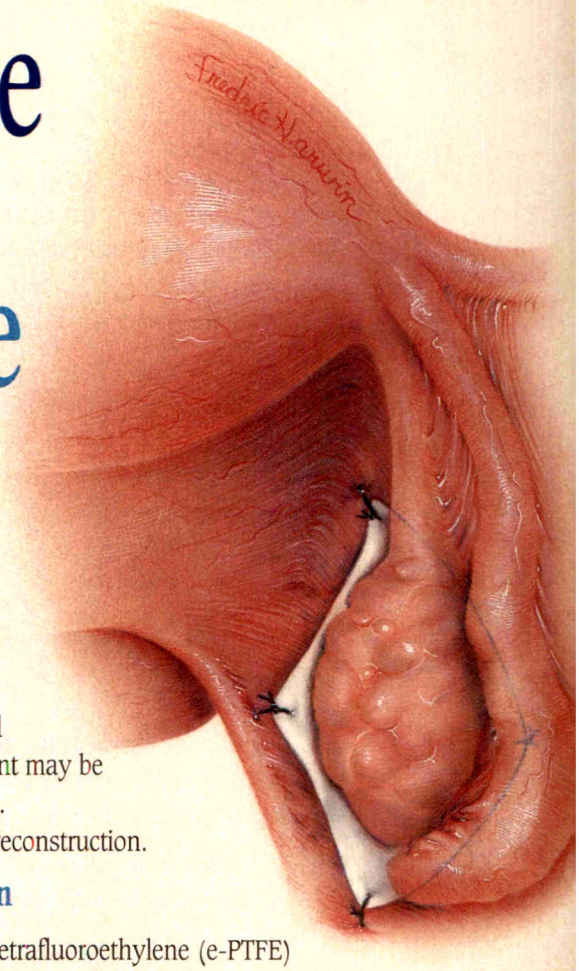
The presence of platelet-activating factor binding sites in human myometrium and their role in uterine contraction 1222

Yan-ping Zhu, PhD, R. Ann Word, MD, and John M. Johnston, PhD

Dallas, Texas

Platelet-activating factor receptors are present in human myometrium; this autacoid causes myometrial contraction, a change in intracellular Ca^{2+}, and myosin light-chain phosphorylation.

Effects of platelet-activating factor on prostaglandin E_2 production by intact fetal membranes 1228



Christine Morris, MB, BS, Haroon Khan, MD, Mark H.F. Sullivan, PhD, and M.G. Elder, MD

London, England

Platelet-activating factor mainly stimulated prostaglandin E_2 production by the chorion-decidual component of human fetal membranes and markedly increased prostaglandin E_2 production after labor.

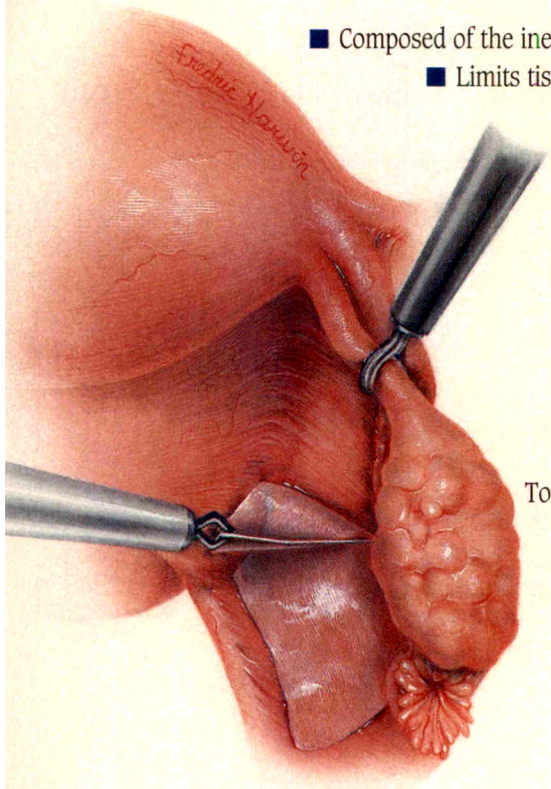
Invariant Performance in Peritoneal Reconstruction of the Pelvic Sidewall



...The GORE-TEX® Surgical Membrane
The Choice in Peritoneal Reconstruction

Surgery of the adnexa often results in post-operative recurrence of clinical equelae, even under the best of circumstances. For a satisfactory result, an adjuvant may be needed to reconstruct and separate deperitonealized areas lost to surgery. The GORE-TEX Surgical Membrane is a product designed expressly for peritoneal reconstruction.

Performance by Design

- Composed of the inert biomaterial, expanded polytetrafluoroethylene (e-PTFE)
- Limits tissue attachment with an extremely small pore size

Proven and Established

- Long record of safety and effectiveness
- 14 years of reliability demonstrated among cardiac surgeons
- Safety substantiated and invariant performance shown for peritoneal repair in a multi-center clinical study

Convenient

- Configured for Peritoneal Reconstruction
- Packaged sterile and **can be resterilized**

To receive further information on the GORE-TEX Surgical Membrane or to consult an application specialist, call **1-800-437-8181**. For orders and overnight delivery, 24 hours a day, please call **1-800-528-8763**.

Papanicolaou smear abnormalities in ambulatory care sites for women infected with the human immunodeficiency virus 1232
Carola Marte, MD, Patricia Kelly, CNP, Mardge Cohen, MD, Rachel G. Fruchter, PhD, Alexander Sedlis, MD, Leza Gallo, MD, Vera Ray, MD, and Carolyn A. Webber, MD
New York and Brooklyn, New York, and Chicago, Illinois

High rates of cytologic abnormality and an association between abnormality and severity of immunodeficiency occurred in 135 human immunodeficiency virus-infected women from three ambulatory care sites.

Intravenous nitroglycerin for uterine relaxation of an inverted uterus 1237
Kenneth M. Altabef, MD, James T. Spencer, MD, and Stanley Zinberg, MD
New York, New York

A case in which intravenous nitroglycerin was used to enable replacement of an inverted uterus is presented.

Severe anti-C hemolytic disease of the newborn 1239
John M. Bowman, MD, Janet M. Pollock, RT, Frank A. Manning, MD, and Chris R. Harman, MD
Winnipeg, Manitoba, Canada

Because C alloimmunization on rare occasions causes hydropic fetal death, criteria for amniocentesis, cordocentesis, and fetal transfusions are the same as for Rh_o (D) alloimmunization.

An integrated therapy for peripartum pelvic instability: A study of the biomechanical effects of pelvic belts 1243
Andry Vleeming, PhD, H. Muzaffer Buyruk, MD, Rob Stoeckart, PhD, Sacid Karamursel, MD, and Chris J. Snijders, PhD
Rotterdam, The Netherlands, and Istanbul, Turkey

The biomechanical effects of pelvic belts used to treat peripartum pelvic instability are studied.

Giant ovarian cyst: Case report 1247
Miguel Zamora-Garza, MD, Joel Rizo, MD, and Alberto Dominguez, MD
Mexico City, Mexico

We report the case of Mexico's largest ovarian cyst surgically treated with good results.

The blood pressure response to infusions of angiotensin II during normal pregnancy: Relation to plasma angiotensin II concentration, serum progesterone level, and mean platelet volume 1249
Masaharu Ito, MD, Toshimitsu Nakamura, MD, Toshihiro Yoshimura, MD, Hideki Koyama, MD, and Hitoshi Okamura, MD
Kumamoto, Japan

Effective angiotensin II pressor doses have a significant positive correlation with circulating angiotensin II and progesterone levels in normal pregnancy.

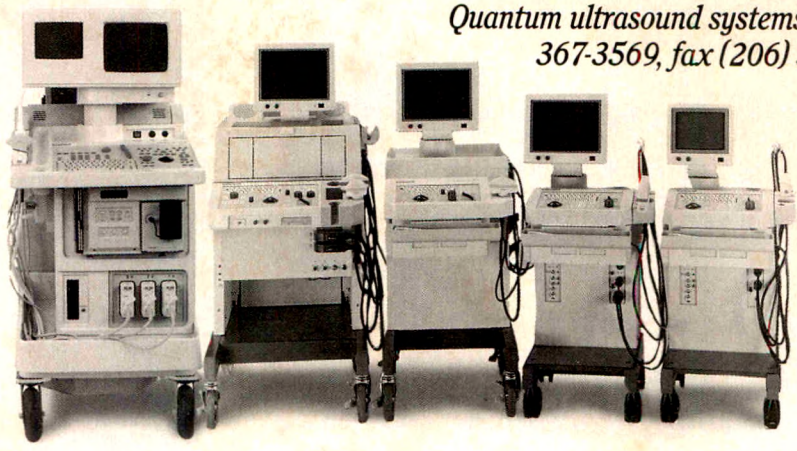
You Have All Kinds Of Reasons To Stay At The Forefront Of Ultrasound.

We Have The Technology To Keep You There.



In offices, clinics and hospitals worldwide, Siemens Quantum is changing the way doctors look at their patients.

Our imaging systems and state-of-the-art diagnostics are pushing the limits of ultrasound. Providing more and better information at every level. Performing more types of obstetric and gynecologic studies than ever before.

The Siemens Quantum alliance joins two powerful forces: Siemens, the world's largest medical imaging company, and Quantum, a pioneer and technological leader in ultrasound.

Together, we're committed to maintaining our leading edge. Which means keeping our systems—and our customers—at the forefront of diagnostic imaging.

The Siemens SONOLINE® SI-200 & 250 are versatile, affordable, compact and easy to use.

And they come with the most advanced, multi-frequency, patient-friendly endovaginal probe on the market.

The Siemens SONOLINE® SI-450 offers superb image quality and a comprehensive set of reports and measurement packages. For complete transabdominal, endovaginal and spectral Doppler capabilities, there's no better equipment for the price.

The Quantum 2000 is a high-performance, high-end, all-purpose system that's unsurpassed for high-definition gray scale and ultra-sensitive color flow. Its advanced technology lets you see subtle differences in tissue, accurately image the tiniest flows, and detect even the smallest details at depth.

To receive more information on Siemens Quantum ultrasound systems, call 1-800-367-3569, fax (206) 391-9161, or write us at 1040 12th Ave. N.W., Issaquah, WA 98027.

Actocardiotocographic monitoring of triplets during vaginal delivery 1293
Jim van Eyck, PhD, and Birgit Arabin, PhD
Zwolle, The Netherlands, and Berlin, Germany

Actocardiotocographic recordings provide a method of optimal fetal monitoring during vaginal delivery of triplets.

Abnormal 1,25-dihydroxyvitamin D metabolism in preeclampsia 1295
Phyllis August, MD, Beth Marcaccio, MD, Joseph M. Gertner, MD, Maurice L. Druzin, MD, Lawrence M. Resnick, MD, and John H. Laragh, MD
New York, New York

Serum levels of 1,25-dihydroxyvitamin D are lower at the time of delivery in women with preeclampsia compared with normotensive and chronically hypertensive pregnant women.

Long-term sequelae of acute pelvic inflammatory disease: A retrospective cohort study 1300
Sharon Safrin, MD, Julius Schachter, PhD, Donna Dahrouge, MPH, and Richard L. Sweet, MD
San Francisco, California

At a median of 37 months after acute pelvic inflammatory disease, frequency of infertility was 40%, chronic pelvic pain 24%, and subsequent pelvic inflammatory disease 43%.

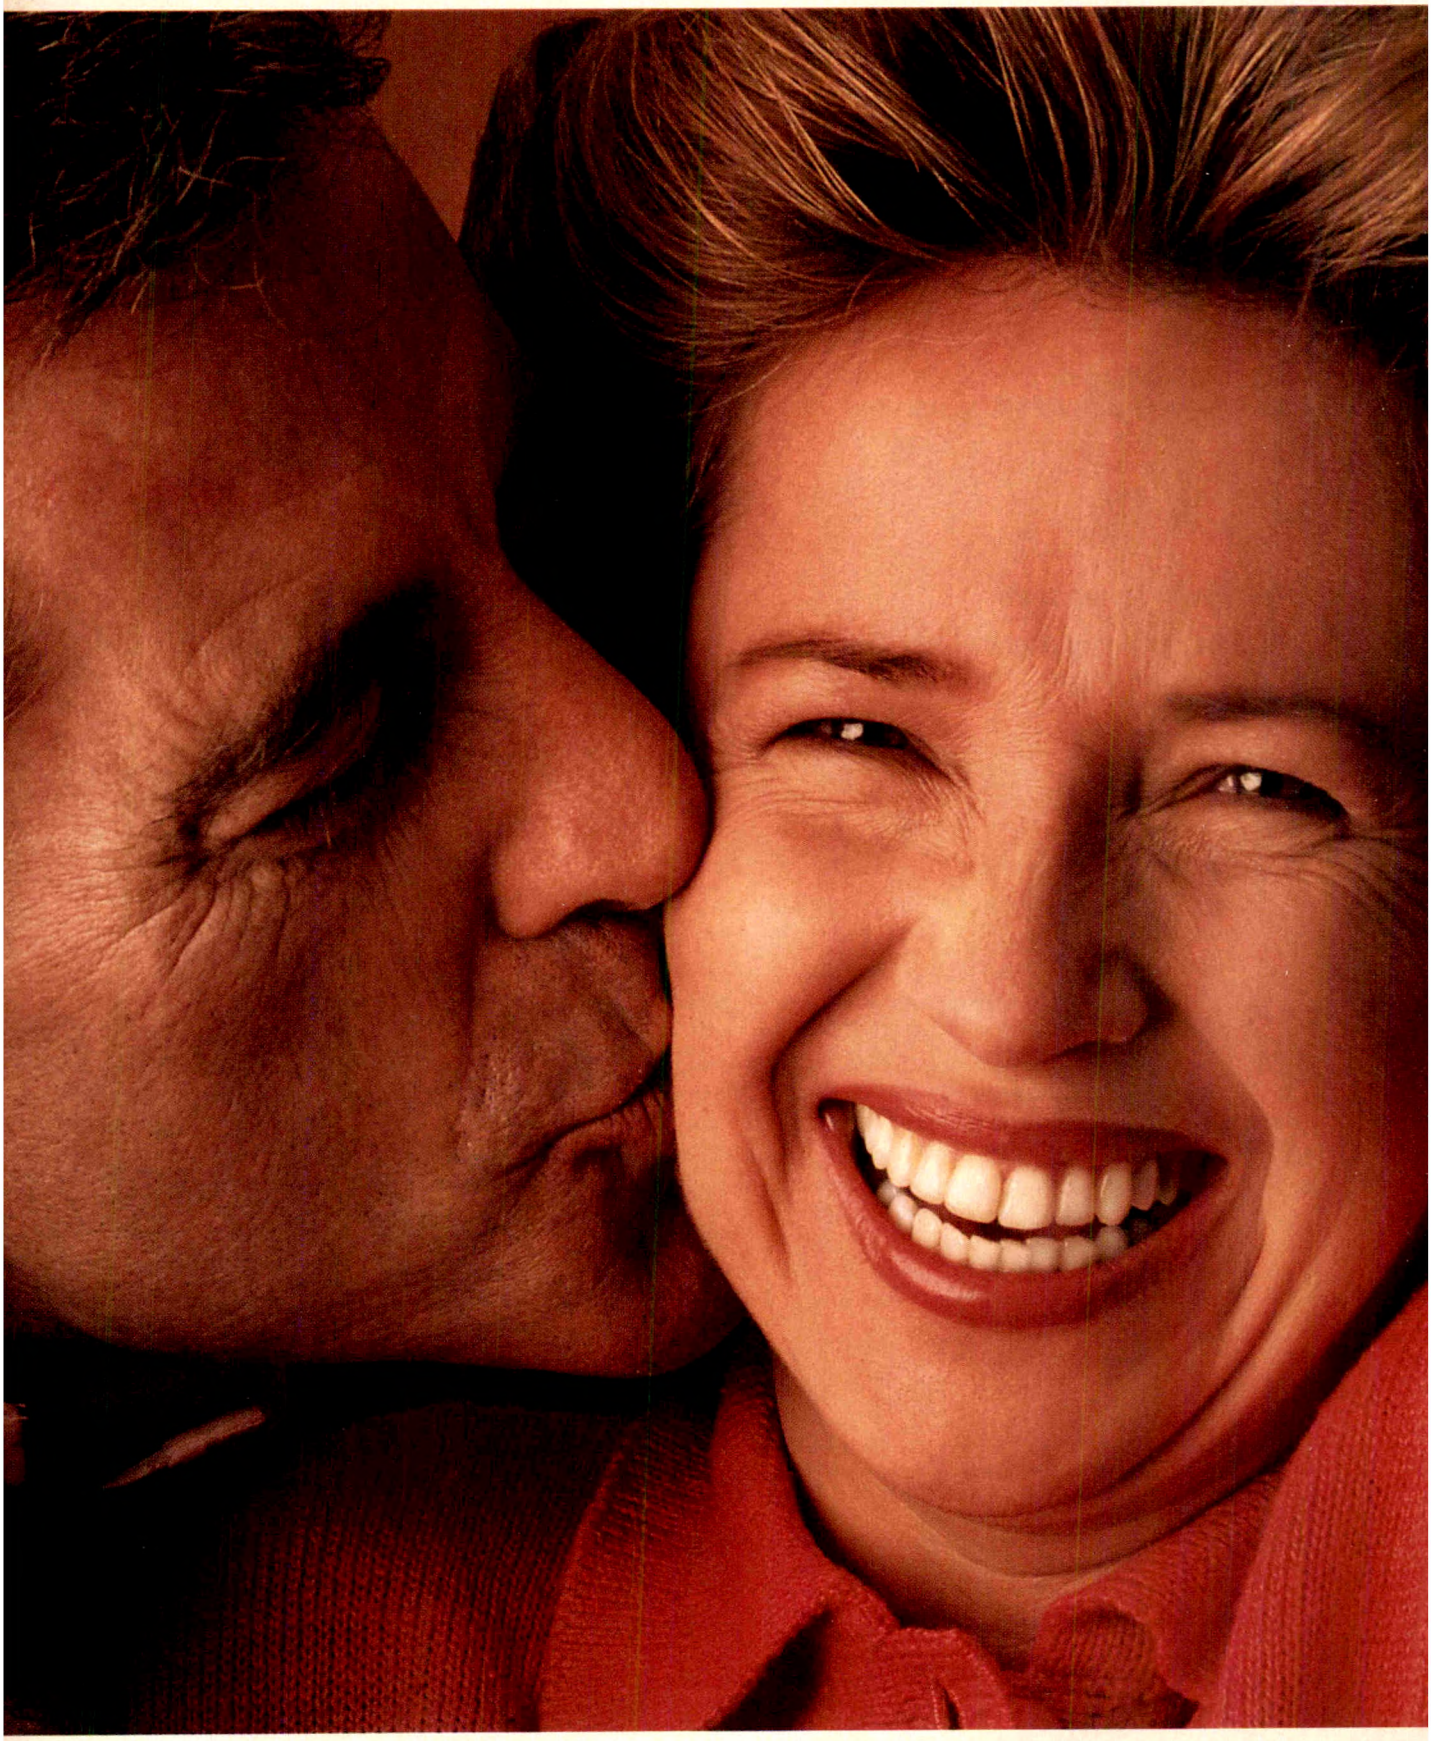
Index to advertisers on page 59A

Make researching easier with the Ten-Year Cumulative Index (1978-1987) to the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY



The Ten-Year Cumulative Index is a complete guide to more than 30,000 pages of original articles, case reports, letters, and editorials published in the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY from 1978 through 1987 (volumes 130 to 157). Numbering more than 800 pages, the Cumulative Index includes both a subject and an author index. This hard-cover volume is $64.50 ($69.00 international). Prices include shipping. *Payment must accompany all orders and must be in U.S. funds, drawn on a U.S. bank.*

Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318 USA; phone (314) 453-4394. In the U.S., call toll-free: 1-800-325-4177, ext. 4394. Please allow six weeks for delivery.

The JOURNAL is abstracted and/or indexed in *Index Medicus, Science Citation Index, Current Contents/Clinical Medicine, Current Contents/Life Sciences, Excerpta Medica, BRS Colleague,* and MEDLINE.

Authorization to photocopy items for internal or personal use is granted by Mosby–Year Book, Inc., for libraries and other users registered with the Copyright Clearance Center (CCC) Transactional Reporting Service, provided that 10¢ per page per copy is paid directly to CCC, 27 Congress St., Salem, MA 01970; phone (508)744-3350. The U.S. Government retains a nonexclusive, royalty-free license in and to any copyright on articles authored by government employees. 0002-9378/92 $00.00 + .10.

You think it's good medicine.

She thinks it's wonderful.

Thanks to you and Premarin®, she could make these years the best years of her life

Hot flashes–Now part of the past for millions of women

Premarin® can dramatically reduce the incidence of hot flashes, night sweats, and related sleep disturbances.

Osteoporosis–No longer part of the future for many women

Premarin® is the first estrogen product proven to prevent postmenopausal osteoporosis in women at risk. And it's the *only* estrogen product proven in studies to reduce the risk of osteoporosis-related fractures by as much as 62%.[1]

Contraindications

Estrogens should not be used in women (or men) with any of the following conditions: known or suspected 1) pregnancy, 2) breast cancer, 3) estrogen-dependent neoplasia, 4) undiagnosed abnormal genital bleeding, 5) active thrombophlebitis or thromboembolic disorders.

Note: Estrogens have been reported to increase the risk of endometrial carcinoma in postmenopausal women.

Nothing else is

PREMARIN®

(conjugated estrogens tablets)

The appearance of this tablet is a trademark of Wyeth-Ayerst Laboratories.

Please see brief summary of prescribing information on last page of this advertisement.

BRIEF SUMMARY *(FOR FULL PRESCRIBING INFORMATION AND PATIENT INFORMATION, SEE PACKAGE CIRCULARS.)*

PREMARIN® Brand of conjugated estrogens tablets, USP
PREMARIN® Brand of conjugated estrogens Vaginal Cream, in a nonliquefying base

1. ESTROGENS HAVE BEEN REPORTED TO INCREASE THE RISK OF ENDOMETRIAL CARCINOMA. Close clinical surveillance of all women taking estrogens is important. Adequate diagnostic measures including endometrial sampling when indicated should be undertaken to rule out malignancy in all cases of undiagnosed persistent or recurring abnormal vaginal bleeding. There is currently no evidence that "natural" estrogens are more or less hazardous than "synthetic" estrogens at equiestrogenic doses.
2. ESTROGENS SHOULD NOT BE USED DURING PREGNANCY.
Estrogen therapy during pregnancy is associated with an increased risk of congenital defects in the reproductive organs of the male and female fetus, an increased risk of vaginal adenosis, squamous-cell dysplasia of the uterine cervix, and vaginal cancer in the female later in life. The 1985 DES Task Force concluded that women who used DES during their pregnancies may subsequently experience an increased risk of breast cancer. However, a causal relationship is still unproven, and the observed level of risk is similar to that for a number of other breast cancer risk factors.
There is no indication for estrogen therapy during pregnancy. Estrogens are ineffective for the prevention or treatment of threatened or habitual abortion.

DESCRIPTION: PREMARIN (conjugated estrogens, USP) contains a mixture of estrogens, obtained exclusively from natural sources, blended to represent the average composition of material derived from pregnant mares' urine. It contains estrone, equilin, and 17α-dihydroequilin, together with smaller amounts of 17α-estradiol, equilenin, and 17α-dihydroequilenin as salts of their sulfate esters. Tablets are available in 0.3 mg, 0.625 mg, 0.9 mg, 1.25 mg, and 2.5 mg strengths of conjugated estrogens. Cream is available as 0.625 mg conjugated estrogens per gram.

INDICATIONS AND USAGE: Moderate-to-severe vasomotor symptoms associated with the menopause. (There is no evidence that estrogens are effective for nervous symptoms or depression which might occur during menopause and they should not be used to treat these conditions.) Prevention and management of osteoporosis (abnormally low bone mass). Atrophic vaginitis. Atrophic urethritis. Hypoestrogenism due to hypogonadism, castration or primary ovarian failure.

PREMARIN (conjugated estrogens) Vaginal Cream is indicated in the treatment of atrophic vaginitis and kraurosis vulvae.

PREMARIN HAS NOT BEEN SHOWN TO BE EFFECTIVE FOR ANY PURPOSE DURING PREGNANCY AND ITS USE MAY CAUSE SEVERE HARM TO THE FETUS (SEE BOXED WARNING).

CONTRAINDICATIONS: Estrogens should not be used in women (or men) with any of the following conditions: 1. Known or suspected pregnancy (see Boxed Warning). 2. Known or suspected cancer of the breast except in appropriately selected patients being treated for metastatic disease. 3. Known or suspected estrogen-dependent neoplasia. 4. Undiagnosed abnormal genital bleeding. 5. Active thrombophlebitis or thromboembolic disorders. 6. Estrogen replacement therapy has not been reported to increase the risk of thrombophlebitis and/or thromboembolic disease. However, there is insufficient information regarding women who have had previous thromboembolic disease.

PREMARIN Tablets and Vaginal Cream should not be used in patients hypersensitive to their ingredients.

WARNINGS: Some studies suggest a possible increased incidence of breast cancer in women taking higher doses of estrogen for prolonged time periods. The majority of studies have not shown an association with usual estrogen replacement doses. Endometrial cancer risk among estrogen users was about 4-fold or greater than in non-users, and appears dependent on treatment duration and estrogen dose. In patients on combined estrogen-progestin therapy, this risk appears to be decreased. (See PRECAUTIONS below.)

Estrogen therapy during pregnancy is associated with an increased risk of fetal congenital reproductive tract disorders.

A 2.5-fold increase in the risk of surgically confirmed gall bladder disease in women receiving postmenopausal estrogens has been reported.

Large doses of estrogen such as those used to treat prostate and breast cancer have been shown to increase the risk of non-fatal myocardial infarction, pulmonary embolism, and thrombophlebitis in men. This cannot necessarily be extrapolated to women. However, to avoid theoretical cardiovascular risk caused by high estrogen doses, the doses for estrogen replacement therapy should not exceed the recommended dose.

Blood pressure should be monitored with estrogen use, especially if high doses are used.

Estrogens may lead to severe hypercalcemia in patients with breast cancer and bone metastases.

PRECAUTIONS: The addition of a progestin for 7 or more days of a cycle of estrogen administration reportedly lowers the incidence of endometrial hyperplasia. Studies of endometrium suggest that 10 to 13 days of progestin are needed to provide maximal endometrial maturation and elimination of hyperplastic changes. Additional risks, such as adverse effects on carbohydrate and lipid metabolism, may be associated with the inclusion of progestin in estrogen replacement regimens. The choice of progestin and dosage may be important in minimizing these adverse effects.

Physical examination and a complete medical and family history should be taken prior to the initiation of any estrogen therapy with special reference to blood pressure, breasts, abdomen, and pelvic organs, and should include a Papanicolaou smear. As a general rule, estrogen should not be prescribed for longer than one year without another physical examination being performed. Conditions influenced by fluid retention, such as asthma, epilepsy, migraine, and cardiac or renal dysfunction, require careful observation. Certain patients may develop manifestations of excessive estrogenic stimulation, such as abnormal or excessive uterine bleeding and mastodynia. Pre-existing uterine leiomyomata may increase in size during estrogen use. Estrogens should be used with care in patients with impaired liver function, renal insufficiency, or metabolic bone diseases associated with hypercalcemia.

The following drug/laboratory test interactions have been reported, some only with estrogen-progestin combinations (oral contraceptives):

1. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3; increased norepinephrine-induced platelet aggregability.
2. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by T_4 levels determined by column or by radioimmunoassay. Free T_3 resin uptake is decreased, reflecting the elevated TBG; free T_4 concentration is unaltered.
3. Impaired glucose tolerance.
4. Reduced response to metyrapone test.
5. Reduced serum folate concentration.

MUTAGENESIS AND CARCINOGENESIS: Long-term, continuous administration of natural and synthetic estrogens in certain animal species increases the frequency of carcinomas of the breast, cervix, vagina, and liver.

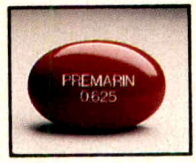
PREGNANCY CATEGORY X: Estrogens should not be used during pregnancy. See **CONTRAINDICATIONS** and Boxed Warning.

NURSING MOTHERS: As a general principle, the administration of any drug to nursing mothers should be done only when clearly necessary since many drugs are excreted in human milk.

ADVERSE REACTIONS: The following have been reported with estrogenic therapy: changes in vaginal bleeding pattern and abnormal withdrawal bleeding or flow, breakthrough bleeding, spotting, increase in size of uterine fibromyomata, vaginal candidiasis, change in amount of cervical secretion; tenderness or enlargement of breasts; nausea, vomiting, abdominal cramps, bloating, cholestatic jaundice; chloasma or melasma that may persist when drug is discontinued, erythema multiforme, erythema nodosum, hemorrhagic eruption, loss of scalp hair, hirsutism; steepening of corneal curvature, intolerance to contact lenses; headache, migraine, dizziness, mental depression, chorea; increase or decrease in weight; reduced carbohydrate tolerance; aggravation of porphyria; edema; changes in libido.

ACUTE OVERDOSAGE: May cause nausea and vomiting.

DOSAGE AND ADMINISTRATION:
PREMARIN® Brand of conjugated estrogens tablets, USP



1. *Given cyclically for short-term use only.* For treatment of moderate-to-severe vasomotor symptoms, atrophic vaginitis, or atrophic urethritis associated with the menopause (0.3 mg to 1.25 mg or more daily). The lowest dose that will control symptoms should be chosen and medication should be discontinued as promptly as possible. Administration should be cyclic (eg, three weeks on and one week off). Attempts to discontinue or taper medication should be made at three- to six-month intervals.
2. *Given cyclically:* Hypoestrogenism. Osteoporosis.
Hypoestrogenism due to: Female hypogonadism—2.5 mg to 7.5 mg daily in divided doses for 20 days followed by 10 day rest period. If bleeding does not occur by the end of this period, the same dosage schedule is repeated. Female castration or primary ovarian failure—1.25 mg daily, cyclically. Adjust upward or downward according to response of the patient. For maintenance, adjust dosage to lowest level that will provide effective control.
Osteoporosis—0.625 mg daily. Administration should be cyclic (eg, three weeks on and one week off).

PREMARIN® Brand of conjugated estrogens Vaginal Cream
Given cyclically for short-term use only. For treatment of atrophic vaginitis or kraurosis vulvae.
The lowest dose that will control symptoms should be chosen and medication should be discontinued as promptly as possible.
Attempts to discontinue or taper medication should be made at three- to six-month intervals.
Usual dosage range: 2 g to 4 g daily, intravaginally, depending on the severity of the condition.
Patients with an intact uterus who are treated with either PREMARIN Tablets or Vaginal Cream should be monitored for signs of endometrial cancer and appropriate measures taken to rule out malignancy in the event of persistent or recurring abnormal vaginal bleeding.

INFORMATION FOR AUTHORS

Editorial policies

The requirements for manuscripts submitted to the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY conform to the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" established by the International Committee of Medical Journal Editors (N Engl J Med 1991;324:424-8). Certain requirements unique to our JOURNAL are provided in Information for Authors, published in each issue of the JOURNAL.

Manuscript submission. Manuscripts should be submitted to one of the two Editors in Chief as follows:

1. **Dr. Zuspan**—manuscripts from the eastern and southeastern United States and from England, Israel, and Italy, manuscripts written for Clinical Opinion and Current Development, Letters to the Editors, and all manuscripts presented before one of the official sponsoring societies, except the Society for Gynecologic Investigation. *Manuscripts from The Society of Perinatal Obstetricians should be submitted to Dr. J. Peter Van Dorsten, P.O. Box 34, MCV Station, Richmond, VA 23298.*
2. **Dr. Quilligan**—manuscripts from states west of Pennsylvania, West Virginia, Kentucky, Tennessee, and Mississippi; manuscripts from Hawaii, Alaska, Canada, and abroad (except England, Israel, and Italy). Dr. Quilligan is responsible for manuscripts from the Society for Gynecologic Investigation. *Manuscripts from the Society for Gynecologic Investigation should be submitted to Dr. Roger A. Lobo, Women's Hospital, 1240 North Mission Road, Room 1M2, Los Angeles, CA 90033.*

Author's suggested reviewers. When authors submit their manuscripts, they must provide the names and addresses of at least three reviewers for consideration by the Editors.

Copyright statement. The specified copyright statement that follows the Information for Authors in each issue of the JOURNAL must be completed, signed by all authors, and submitted with the manuscript. If not completed in full, it will be returned to the author for completion. The copyright statement and checklist form may be torn from the JOURNAL or photocopied for submission.

Checklist. The checklist that appears with the copyright statement in each issue of the JOURNAL must be fully completed by the author(s) and sent with each submitted manuscript. A more complete description of each item that must be checked is provided under the appropriate heading in the Information for Authors, which is published in each issue of the JOURNAL. *If the checklist is not completed in full, the deficiencies will be noted, and the form, as well as the manuscript when necessary, will be returned to the author for completion.*

Previous publication. If a report by the same author(s) or some of the same authors has been previously published in any medium that deals in any respect whatsoever with the same patients, same animals, same laboratory experiments, or same data, in part or in full, as those reported in the manuscript being submitted, two reprints of the article(s) or two copies of the manuscript, be it a full-length report or an abstract, must be submitted with the manuscript. Two copies of a new manuscript being prepared for possible publication also must be submitted. The author(s) should inform the Editor of the circumstances, similarities, and differences of the reports. This requirement also applies to the submission of a manuscript in which a few different patients, animals, laboratory experiments, or data were added to those reported in a previous publication or in a submitted or accepted manuscript. Articles previously published in another language will not be considered.

Human and nonhuman experimentation. It is assumed by the Editors that manuscripts emanating from a particular institution are submitted with the approval of the

requisite authority. Human experimentation that requires local institutional approval must have this approval *before the experiment is started* and approval must be so indicated in the *Material and Methods* section of the submitted manuscript. Reports of experiments on nonhuman animals or other species must *state in the* Material and Methods *section of the manuscript* that the guidelines for the care and use of the animals *approved by the local institution* were followed. The type of nonhuman animals or other species used in an investigation must be named in the title, abstract, key words, and *Material and Methods* section of the manuscript.

Authorship. For manuscripts with two or more authors, each author must qualify by having participated actively and sufficiently in the study that is being performed and reported. The inclusion of each author in the authorship list of a report is based only (1) on substantial contributions to (a) concept and design, or analysis and interpretation of data and (b) drafting the manuscript or revising it critically for important intellectual content; and (2) on final approval by each author of the version of the manuscript. Conditions 1 (a and b) and 2 must both be met. Others contributing to the work should be recognized separately in an Acknowledgment. *In the covering letter that accompanies the submitted manuscript, it must be confirmed that all authors fulfilled both conditions.*

Conflict of interest. Authors are expected to inform the Editor, in a letter accompanying the submitted manuscript, of any commercial association that might pose a conflict of interest, such as ownership, stock holdings, equity interests and consultant activities, or patent-licensing situations. Such information is confidential, is not given to the consultants, and does not play a part in the decision of the quality or timeliness of the manuscript. If the manuscript is accepted, the author and the Editor will determine how best to release the information. The usual and customary listing of sources of support and institutional affiliations on the title page is proper and does not imply a conflict of interest; only where there is a possible conflict of interest is the author(s) expected to inform the Editor.

Disclaimer. Statements and opinions expressed in articles and communications herein are those of the author(s) and not necessarily those of the Editor(s) or Publisher, and the Editor(s) and Publisher disclaim any responsibility or liability for such material. Neither the Editor(s) nor the Publisher guarantees, warrants, or endorses any product or service advertised in this publication, nor do they guarantee any claim made by the manufacturer of such product or service.

General requirements for preparation of manuscripts

The original and two good-quality photocopies of the manuscript and three sets of black-and-white glossy prints of illustrations are required. See "Color figures" and "Computer-generated figures" for special requirements. Manuscripts must be submitted in English.

Manuscripts must be typed double-spaced on one side only of 22 × 28 cm (8½ × 11 inch) white bond paper with 1-inch margins at top, bottom, and sides. Number pages consecutively in the upper right-hand corner in the following order: title page, condensation, abstract, body of text, acknowledgments, references, figure legends, and tables.

Title page. The title page (page 1) should contain in sequence the title (concise and suitable for indexing purposes); author line with first name, middle initial, and last name of each author and each author's highest academic degree (both MD and PhD are acceptable, but honors degrees are not permitted); city(ies), state(s) in which the study was conducted; divisional, or departmental, and institutional affiliations at the time the study was performed; source(s) of financial support; presented line, if applicable; disclaimers, if any; name, address, business and home telephone numbers, and fax number of author to whom requests for reprints should be addressed (if reprints will not be available, it should be so stated); and name, address, business and home telephone numbers, and fax number of author responsible for correspondence concerning the manuscript if different from author to whom reprint requests are addressed. *At the bottom of the title page supply a short title for the running head not exceeding 52 characters (including word spaces).*

Condensation. On page 2 of the manuscript provide a brief, concise condensation, typed double-spaced, that will appear with the title in publication of the Contents pages of the JOURNAL. It should be a single sentence, limited to a maximum of 25 words, delineating the essential point(s) made in the manuscript.

Abstract page including key words/phrases. On manuscript page 3, type the abstract, double-spaced, with the required margins and headed by the title of the article and name(s) of author(s). Below the abstract, list 3 to 5 *key words or short phrases* for indexing purposes.

A structured abstract is required for certain types of articles and a *standard abstract format* is required for other types of articles; therefore the author(s) should select and prepare the appropriate abstract to be used in the submitted manuscript. This applies to both independently submitted and society manuscripts.

Structured abstract. A structured abstract, limited to 150 words, is to be used for regular articles, society articles, and Current Investigation articles; excluded are Clinical Opinion, Current Development, case report, and brief communication articles. The structured abstract is to contain the following major headings: *Objective(s); Study Design; Results;* and *Conclusion(s).* The *Objective(s)* reflects the purpose of the study, that is, the hypothesis that is being tested. The *Study Design* should include the setting for the study, the subjects (number and type), the treatment or intervention, and the type of statistical analysis. The *Results* include the outcome of the study and statistical significance if appropriate. The *Conclusion(s)* states the significance of the results.

Standard abstract. The standard abstract format is required for Clinical Opinion, Current Development, case report, and brief communication articles. The standard abstracts for Clinical Opinion and Current Development articles are to be 50 to 150 words and standard abstracts for case reports and brief communications are limited to 50 words. Even though the formal names of these four types of articles are not used, an author should determine his/her type of manuscript and prepare the appropriate standard abstract, regardless of whether it is to be submitted independently or as a part of a society's transactions.

Text. Do not hesitate to write your manuscript in the first person and active voice if they are more appropriate to the information you wish to convey. The passive voice is generally more effective for describing techniques or observations, since the emphasis is on the "action" rather than on the person performing the action.

Only standard abbreviations are to be used. Consult the

Estimating length of manuscripts

With the exception of Current Development articles, the length of text material (introduction through *Comment* section) in regular manuscripts accepted for publication normally ranges from 750 to 4200 words (an average of 2000 words). A text of 4200 words or more can seldom be accepted, especially if tables and figures are included. The average manuscript of 2000 words of text with abstract, 3 tables with captions, 2 figures with legends, and references makes a 5.7-page article in the JOURNAL. The 2000 words of text alone makes approximately 8 pages of manuscript typed double-spaced with the required 1-inch margins (approximately 250 words per page). A table or figure that occupies both columns of half a JOURNAL page is equivalent to approximately 500 words in manuscript. Thus, if a greater number of illustrations and tables is used, the length of the text should be adjusted accordingly.

Council of Biology Editors Style Manual or the AMA's *Manual of Style.* Abbreviations in the title are not acceptable. They should be avoided, if possible, in the abstract. In the text they should be kept to a practical minimum. The full term for which an abbreviation stands should precede its first use in the text unless it is a standard unit of measurement.

Either the generic, chemical, or proprietary names of drugs may be used. If the generic or chemical name is used, authors may, if they desire, insert the proprietary name in parentheses after the first mention in the text, with the name of the manufacturer and city and state.

Regular articles are customarily organized into the following sections: an introduction and headings that identify *Material and Methods*, *Results*, and *Comment.* Authors may wish to summarize their findings in a short paragraph at the end of the *Comment* section. This format may not be appropriate for some types of articles.

In the introduction, state concisely the purpose and rationale for the study and cite only the most pertinent references as background.

In the *Material and Methods* section describe briefly (but in sufficient detail to permit other workers to repeat the study) the plan, the patients, experimental animals or other species, material, and controls, the methods and procedures utilized, and the statistical method(s) employed.

In the *Results* section present the detailed findings. Include mentions of all tables and/or figures. Figures and tables should supplement, not duplicate, the text; presentation of data in either one or the other will suffice. Emphasize only your important observations; do not compare your observations with those of others. Such comparisons and comments are reserved for the *Comment* section.

In the *Comment* section state the importance and significance of your findings but do not repeat the details given in the *Results* section. Limit your opinions to those strictly indicated by the facts in your report. Compare your findings with those of others. No new data should be presented in this section.

Acknowledgments. Acknowledge only persons who have made substantive contributions to the study.

References. A reasonable number (25) is allowed, except in case reports and brief communications (limited to 2) and in manuscripts for the Current Development section (for which there is no limit). Number references consecutively in the order in which they are mentioned in the text. Use the format of the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" (Vancouver style) (N Engl J Med 1991;324:424-8). Journal titles should conform to abbreviations used in *Cumulated Index Medicus.*

Examples (if six or fewer authors, list all; if seven or more authors, list three then et al.):

JOURNAL: Flamm BL, Dunnett C, Fischermann E, Quilligan EJ. Vaginal delivery following cesarean section: use of oxytocin augmentation and epidural anesthesia with internal tocodynamic and internal fetal monitoring. AM J OBSTET GYNECOL 1984;148:759-63.

BOOKS: Ledger WJ. Dystocia and prolonged labor. In: Wilson JR, Carrington ER, eds. Obstetrics and gynecology. St. Louis: CV Mosby, 1987 vol 8:474-93.

Personal communications and unpublished data, if essential, may be used but not as numbered references. If they are used, they are to be referred to, within parentheses, at the appropriate location in the text. If used, the author(s) must obtain written and signed permission for their use from the individual being quoted. *This signed permission must accompany the manuscript when it is submitted to the Editor.* Published abstracts can be used as numbered references; however, reference to the complete published article is preferred.

Figures. The term *figure* includes all types of illustrations such as graphs, diagrams, photographs, flow charts, and line drawings. A reasonable number of figures will be reproduced without charge, but special arrangements must be made with the Editors for color figures at an additional charge to the author. The quoted charge is per page of color, and as many as eight color figures can be included on one page if the color balance is appropriate.

Figures must be cited consecutively in the text in Arabic numerals and identified with a gummed label on the back of the figure with author(s) name(s), title of article, figure number, and top marked clearly. Consistency in size within the article is strongly preferred. Any special instructions regarding sizing should be clearly noted. Do not use paper clips or mar the surface of figures in any way. Figures will be returned only on request by the author.

For *black-and-white figures,* submit three sets of 3 × 4 inch (minimum) to 5 × 7 inch (maximum) unmounted, glossy prints. All lettering must be done with commercially available paste-on letters (or numbers) or by a professional; typed or freehand lettering is not acceptable. All lettering must be in proportion to the drawing, graph, or photograph. Original drawings, appropriately done in black India ink, roentgenograms, and other material must be submitted as glossy prints with good black-and-white contrast.

For *color figures* submit original transparencies and two sets of unmounted prints on glossy (smooth surface) paper. Polaroid prints are not acceptable. Color transparencies must have a color balance (consistency in lighting and film speed) that is acceptable to the author and Editors before acceptance for publication. Please note that 35 mm transparencies are enlarged to twice their original size. If it is important to deviate from this standard, please so indicate when the material is submitted. The top, first author's last name, and figure number must be indicated on the front of each transparency and the back of each print.

Computer-generated figures must be legible and clearly printed in jet black ink on heavy coated paper with either a glossy or dull finish. Any patterns or shadings must be dark enough for reproduction and must be distinguishable from each other. Lines, symbols, and letters should be both smooth and complete. The legend should not appear on the figure. On the back of each figure the name of the first author and the figure number should be given and the top indicated. Three original individual laser or plotter prints are to be submitted *unmounted* with the manuscript. Laser prints should be full size at 300 dots per inch (DPI) or greater full-page resolution; multiple illustrations on a page cannot be accepted. Dot matrix prints and photographic halftones are not acceptable. *Color figures* are acceptable, but special arrangements must be made with the Editors. The colors used must be dark enough and of sufficient contrast for reproduction. With the exception of fluorescent colors, all colors can be reproduced in four-color figures. The preparation and submitting of color prints should follow the preceding guidelines for black-and-white computer-generated illustrations.

Legends to figures. Legends for all figures must be typed together in numeric order double-spaced on one sheet of paper (or more if necessary) separate from the text of the manuscript. This page must be numbered in sequence after the references. Titles should be included in the legend, not on the print. Original magnifications should be provided. If a figure has been taken from copyrighted material, the legend must give full credit to the original source.

Tables. Tables should be typed on separate sheets of paper, one table to a page, and included at the end of the text. They should be numbered in Roman numerals. Each table must be cited in sequence at an appropriate point in the text. Titles should be brief yet indicate clearly the purpose or content of each table, and each column should be precisely defined by headings. Abbreviations and special designations should be explained in a footnote to the table. If a table or any part thereof has been taken from copyrighted material, a footnote to the table must give full credit to the original source. Arrangements must be made with the Editors for elaborate tables because of space limitations.

Permissions. Direct quotations, tables, or figures that have appeared in copyrighted material must be accompanied by written permission for their use from *the copyright owner and original author* along with complete reference information. Photographs of identifiable persons must be accompanied by signed releases. If not, all recognizable features must be masked.

Requirements for certain types of manuscripts

Case reports and brief clinical and basic science communications. Limit of 700 words, 2 references. Include *standard abstract format*, of 50 words maximum, 3 to 5 key words/phrases for indexing purposes, and short title. If tables and/or figures are used, an equivalent number of words must be deducted from the total (see "Estimating Length of Manuscript").

Current Investigation. Same requirements as for regular article. The abstract *must* follow the *structured format.*

Clinical Opinion. Limit of 3000 words. Include *standard abstract format* of 50 to 150 words, 3 to 5 key words/phrases, and short title. Submit to Dr. Zuspan.

Current Development. Limit of 6000 words. Include *standard abstract format* of 50 to 150 words, 3 to 5 key words/phrases, and short title. Submit to Dr. Zuspan.

Letters to the Editors. *Letters to the Editors* must be submitted in duplicate, typed double-spaced, and the text of the manuscript must be limited to a maximum of 400 words (excluding references, name[s] and address[es] of the signer[s], and the phrase "To the Editors"). The submitted *Letter to the Editors* must be accompanied by a signed copyright statement. If there are two or more signers of the *Letter to the Editors,* one of the authors may sign the copyright statement but must add to the statement the following: "I sign for and accept responsibility for releasing this letter on behalf of any and all cosigners." These requirements apply to all types of *Letters to the Editors.* Letters should be sent to Dr. Zuspan.

Two types of letters will be considered for publication. (1) A *Letter to the Editors* commenting on an article that has appeared in the JOURNAL should be brief and directly related to the published article. The editorial staff reserves the right to shorten letters if necessary and to make minor editorial alterations without reference to the writer. Letters may be published together with a reply from the original author. If the original author does not respond, a notation indicating "Response declined" will be published. As space for letters is limited, only a selection of letters submitted may be published. (2) A brief case presentation or a short report of a pertinent observation in the form of a *Letter to the Editors* will be considered for publication.

Announcements. Announcements of major meetings and other significant activities must be received at least 8 weeks before the desired month of publication. All announcements carry a charge of $60 U.S., and the fee must accompany the request to publish. Information will be limited to title of meeting, date, place, and an address to obtain further information. Send announcements and payment, payable to this JOURNAL, to Kay G. Goehler, Senior Manuscript Editor, Journal Editing, Mosby–Year Book, Inc., 11830 Westline Industrial Drive, St. Louis, MO 63146-3318.

Books. Books received will be listed in the JOURNAL. They should be sent to Dr. Zuspan. No books will be returned.

Reprints

The corresponding author will receive a price schedule and order form at the time of publication. Reprints in quantities must be ordered from the Publisher with the author's consent.

Business communications

Communications of a business nature and all advertising communications should be addressed to: Journal Publisher, Mosby–Year Book, Inc., 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, or call Journal Advertising Production Manager (1-800-325-4177, ext. 4306, or 314-453-4306).

CHECKLIST AND COPYRIGHT STATEMENT

Both the checklist and the copyright statement forms **must be completed** and sent with each submitted manuscript. If **not** completed, these forms will be returned to the author for completion.

These items appear in each monthly issue of the JOURNAL. A photocopy may be used. An exposition of the requirements given in the checklist is in the Information for Authors, which is published in each issue of the JOURNAL.

CHECKLIST

General

—The original and two copies of the manuscript are submitted.
—The completed checklist is enclosed. The assignment of copyright signed by **all** authors accompanies the manuscript.
—Human experimentation has been approved by the local institution as stated in the *Material and Methods* section.
—Guidelines for the care and use of *nonhuman* animals or *other species* approved by the institution have been followed as indicated in the *Material and Methods* section. *The species is named in the title, abstract, key words, and* Material and Methods *section.*
—The covering letter with essential information is with the manuscript.
—All elements of the manuscript are typed in English double-spaced on bond paper with 1-inch margins at top, bottom, and sides.
—All pages are numbered in the following order: title page, condensation, structured or standard abstract, body of the text, acknowledgments only of persons who have made substantive contributions to the study, references, legends, and tables.
—Signed, written permission from both the copyright holder and the original author for the use of tables, figures, or quotations previously published and their complete references are enclosed with the manuscript.
—Signed, written permission for the use of quotations of personal communications and unpublished data has been obtained from the person(s) being quoted and is enclosed.

Authorship

—In the covering letter that accompanies the submitted manuscript I/we have confirmed that all authors fulfilled both conditions required for authorship.

Conflict of interest

—In the covering letter that accompanies the submitted manuscript the commercial association of the author or of any coauthors that might pose a conflict of interest is described.

Previous publications

—Enclosed with the submitted manuscript are two reprints each of articles the author and/or some of the coauthors have previously published, have submitted for possible publication, or have in manuscript form dealing with same patients, same animals, same laboratory experiment, or same data, in part or in full, as those reported in the submitted manuscript. Further explanation is provided in the covering letter that accompanies the submitted manuscript.
—Similarities, differences and explanation are provided in the covering letter that accompanies the submitted manuscript.

Reviewers

—Names and addresses of three suggested reviewers are enclosed.

Title page

—These elements are given in the following sequence, and are typed double-spaced.
—Title.
—Author(s) name(s) and highest academic degree(s) are shown.
—City(ies), state(s), and country other than United States in which the study was conducted are given.
—The name(s) of the institution(s) section(s), division(s), department(s) in which the study was performed is provided and the institutional affiliation(s) of the author(s) at the time of the study is indicated.
—Acknowledgment of financial support is cited.
—Name, address, business and home telephone numbers, and fax number of author to whom requests for reprints are to be sent are included.
—If reprints will not be available, this has been stated on the title page.
—If the corresponding author is different from the author to whom reprint requests are to be sent, his/her name, address, business and home telephone numbers, and fax number have been added.
—At the bottom of the page, a running head not exceeding 52 characters (including word spaces) has been typed.

Condensation

—On a separate sheet of paper, page 2 of the manuscript, a single sentence limited to 25 words delineating the essential point(s) is typed double-spaced.

Abstract and key words or short phrases

—The abstract (structured or standard format) is typed double-spaced with required margins on page 3 headed by the title and author(s) name(s). Beneath the abstract 3 to 5 key words or short phrases are typed.
—A *structured abstract,* with 150 words or less, is submitted as required for regular articles, society regular-type articles, and Current Investigation articles. The abstract contains the four required major headings: Objective(s), Study Design, Results, and Conclusion(s), each with a brief adequate presentation.
—A *standard abstract* is submitted as required for Clinical Opinion and Current Development articles with 50 to 150 words and for case reports and brief communications articles with a maximum of 50 words, be they independent or society articles.

References

—Are typed double-spaced.
—Are numbered consecutively in the order they are cited in the text.
—The format of the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" is used. Examples shown in Information for Authors have been followed.
—Personal communications and unpublished observations are not used as numbered references but are mentioned in the text with the written approval of the person being quoted. The signed approval is enclosed.

Figures

—Each is numbered with an Arabic numeral and cited in numeric sequence in the text.
—Three sets of unmounted glossy prints for *black-and-white* figures are submitted, properly numbered, labeled, and *top indicated* on the back of each print.
—Three sets of original computer-generated figures printed on heavy coated paper with either a glossy or dull finish, unmounted, each one on a page, and properly labeled on the back and *top indicated* are submitted. None are dot matrix or photographic prints.
—Original transparencies of *color photographs* appropriately numbered and identified and *top indicated* are submitted along with two sets of unmounted prints on glossy paper, numbered and identified on the back.

Figure legends

—Are provided for each figure.
—Are numbered and typed together in numeric order on one sheet of paper (more if necessary). The page is numbered in sequence after the References page(s).

Tables

—Each table headed by a title and numbered in Roman numerals is typed double-spaced on a separate page.
—Tables are cited in numeric sequence in the text.

TRANSACTIONS OF THE TENTH ANNUAL MEETING OF THE AMERICAN GYNECOLOGICAL AND OBSTETRICAL SOCIETY

Abortion or motherhood, suicide and madness

Kenneth J. Ryan, MD

Boston, Massachusetts

This is the first presidential address for this society in three years. Because of personal or family illness, the last two presidents unfortunately had no opportunity to exercise this distinct honor and privilege. I count myself lucky therefore to be able to stand before you, in what is for me a life-affirming event, and renew the tradition of the presidential address at a meeting of The American Gynecological and Obstetrical Society.

I have chosen neither a safe nor an easy subject for this presentation, but one which is instead provocative and morally contentious. The title is "Abortion or Motherhood, Suicide and Madness." I have chosen this title to highlight the political turmoil abortion engenders. When Joseph Califano, Secretary of Health, Education, and Welfare under the Carter Presidency, asked a special group to come up with alternatives to abortion, which he and Carter opposed, the report concluded that the only real alternatives are "suicide, motherhood and some would add, madness."[1]

Abortion is a worldwide problem. In the 1970s, there were twice as many abortions as births in the Soviet Union. In France births equaled abortions, while in England, with very liberal abortion laws, there were six times as many births as abortions. In Brazil, Italy, Japan, Portugal, Spain, Sweden, and Yugoslavia the average was 1.5 to 3 births for every termination. In many of these countries abortions are illegal and the numbers are estimates. In most cases the number of abortions seemed to be connected to the availability of sex education, contraceptives, and birth control programs rather than laws.[2]

From the Department of Obstetrics, Gynecology, and Reproductive Biology, Harvard Medical School.

Presidential Address presented at the Tenth Annual Meeting of the American Gynecological and Obstetrical Society, Carlsbad, California, September 5-7, 1991.

6/6/35921

Indeed, the place of abortion in our society is crying out for a fair and rational yet civilized discussion. I will try to give you one. The frustration of dealing with the topic of abortion today was well summed up by Anna Quindlen in a *New York Times* book review of Laurence Tribe's *Abortion, the Clash of Absolutes.* Ms. Quindlen wrote: "The last time I was on a panel on the subject of abortion, the adrenaline flowed like wine and I made a solemn vow: that I would never again engage in public debate on the subject. It was not simply that it was difficult, and bitter, and personal, and nasty. It was that it led nowhere. At the end of almost three hours, none of us had budged from our original positions. There was heat, but no light. It was a 'clash of absolutes.'"[3] It has not always been so difficult to have an unemotional discussion on abortion. The change to implacable, polarized positions on the subject followed in the aftermath of the Supreme Court decision on *Roe v Wade* in 1973.[4] We will review what led up to and followed this momentous and unexpected change in abortion laws in the United States.

On Jan. 22, 1973, the decision of the Supreme Court not only declared the criminal abortion laws of Texas and Georgia unconstitutional but mandated some revision in abortion statutes for almost every other state of the Union. It was a remarkable decision, passed by a vote of 7 to 2 with three of Nixon's four court appointees not only siding with the majority but one of them (Blackmun) delivering the majority opinion. Only John F. Kennedy appointee Byron White and Nixon appointee William Rehnquist voted in the minority. I remember that Monday distinctly since I had just arrived at Harvard and the Boston Lying-in Hospital to take up a new post 3 weeks earlier. The hospital public relations office called and insisted that I give an immediate press conference so they could deal with a barrage of calls from the news media. There was considerable interest in Massachusetts about what the change in law meant in practical terms since almost all

local women seeking an abortion up to this time were forced to travel to New York, which had repealed its antiabortion statutes in 1970. The reporters all wanted to know when that could stop. At the conference I welcomed the Supreme Court decision to make abortion largely a matter between a woman and her physician and hoped that there would be enough medical support in Massachusetts so that patients would not have to travel for care. My short vignette on all the television channels was followed by Archbishop (later Cardinal) Humberto Medeiros of Boston asserting that abortion was nothing less than murder. It was a chilling reception to the new politics of abortion.

Some background of the Supreme Court case provided by Laurence Tribe[5] is fascinating. The Roe of *Roe v Wade* was a pseudonym for Norma McCorvey who explained that, at age 25 and unmarried, she was gang raped when walking home from work in 1969. Abortion was illegal in Texas except to save a woman's life and she claimed she couldn't afford to travel to obtain a legal abortion elsewhere. Although that pregnancy was no longer at issue by the time the appeal reached the Supreme Court, the case was still heard since no case concerning pregnancy could otherwise reach settlement, and the justices reasoned that the plaintiff might even be pregnant and have a similar problem in the future. Ironically McCorvey admitted 15 or so years later that she hadn't been raped but made up the story to hide the fact that she'd gotten pregnant in a more usual manner. The Wade of *Roe V Wade* was a Dallas county prosecutor who is sued regularly whenever a Texas law is challenged.

A companion complaint was heard at the same time: *Mary Doe* (a pseudonym) *v Bolton* (Attorney General of Georgia). Mary Doe was really Sandra Race Cano, a 22-year-old married Georgia citizen who was 9 weeks pregnant with three living children. Two of the oldest children were placed in a foster home because Mary Doe was too poor and couldn't care for them. The youngest child was placed for adoption. Her husband had abandoned her and she was living with her indigent parents and their eight children. She had been a mental patient. Although she became reconciled with her husband, he was a construction worker who had only sporadic jobs. She was advised that having an early abortion would be less dangerous to her than carrying the pregnancy to term. The abortion committee of the Grady Memorial Hospital denied her request as not complying with the Georgia law. The Georgia statute was actually more enlightened than that of Texas. In Georgia an abortion was possible on grounds of threats to the woman's life or health, rape, or if the fetus would be born with serious defects. The procedure had to be performed in an accredited hospital and approved by a staff abortion committee, and the decision had to be concurred with by two additional physicians. Mary Doe eventually had the child, Melissa Able, who is now herself a mother. Ironically, today Mary Doe is active in the pro-life movement and her daughter (who obviously wouldn't have been born if aborted in 1969) is pro-choice.[4,5] Norma McCorvey, the original Roe, is still pro-choice.

The chief architect of the *Roe v Wade* decision was Harry Blackmun, who finally filled the seat vacated by Abe Fortas in 1970 after two prior Nixon nominees, Judges Haynsworth and Carswell, had failed the approval process. Blackmun was considered a moderate conservative but neither Nixon nor his attorney general, Mitchell, knew his judicial philosophy. The "litmus" test applied to prospective court nominees for beliefs on abortion hadn't yet gained currency. Nixon reportedly at least wanted to be assured that Blackmun's three daughters in their 20s were not "hippie types." They weren't. It was a happy coincidence that Blackmun had been general counsel to the Mayo Clinic for 10 years, which undoubtedly prepared him for dealing with the medical aspects of his report.[6]

Justice Blackmun, writing for the Supreme Court, concluded that a woman's right to terminate a pregnancy was so fundamental that government could not interfere with the exercise of that right except for compelling reasons. In the first trimester the government could not interfere except to insist that a physician perform the abortion. In the second trimester regulation might involve only procedures to protect the woman's health. In the third trimester, after viability was achieved, the state could protect fetal life and prohibit abortions unless the life or health of the woman was threatened. Blackmun reviewed the history of abortion from Greek and Roman times, through the English common law and nineteenth-century American state laws. He recognized the controversy about the Hippocratic oath and the Pythagorean origins for the injunction against abortion. In common law, abortion was not considered a crime before quickening, and whether it was felony or misdemeanor after quickening is in dispute. Later abortion laws were supposedly designed to protect the health of the woman and to require that only physicians do a "legal" abortion.[4]

Support in the Constitution was sought by the justices in the liberty clause of the Fourteenth Amendment as a right of privacy in reproductive matters and in the unenumerated rights reserved for the people in the Ninth Amendment. This was the basis for two prior court decisions on the use of contraceptives if married (*Griswold v Connecticut,* 1965) and if unmarried (*Eisenstadt v Baird,* 1972). In deciding whether Roe was decided correctly, I rely on Laurence Tribe, a constitutional lawyer who has prevailed in some 16 of 20 appearances before the Supreme Court. Tribe points out

that our protection by the Bill of Rights does not apply to actions of state governments but specifies only what Congress cannot do. It is the Fourteenth Amendment, enacted in 1868, that prohibits the states from making or enforcing laws that abridge our rights as United States citizens and prohibits the states from depriving us of life, liberty, or property without due process of law. This liberty clause applies the Bill of Rights to the states, although according to Tribe some provisions of the Bill of Rights are still not protected in all states. Judge Robert Bork, whose nomination to the Supreme Court failed in 1987, has been an outspoken critic of *Roe v Wade*. His feeling is that the court should not enumerate rights not written in the constitution and the liberty clause of the Fourteenth Amendment could be abridged by adequate "due process of law." Although not specified in the Constitution, the right to privacy was invoked prior to the Griswold and Baird decisions in the Supreme Court rulings in 1923 *(Meyer v Nebraska)*, which allowed parents to teach their children German over state objections due to the war, and in 1925 *(Pierce v Society of Sisters)*, which overruled state laws that would have shut down parochial schools. In 1967, the Court struck down state law against interracial marriage *(Loving v Virginia)*. In *Skinner v Oklahoma* (1942) the court recognized the right of reproduction by striking down a sterilization law for criminals. The Supreme Court has also invalidated criminal convictions based on evidence obtained from stomach pumping and from surgical removal of a bullet from a suspect. Clearly some right to privacy must be implicit in these prior findings. Tribe quotes Judge Bork as saying: "The right to abort, whatever one thinks of it, is not to be found in the Constitution." Tribe responds that neither are such words as freedom of marital choice, freedom of parenthood, and family self-determination and, one might add, freedom to use contraceptives. The privacy and liberty issues are broader than the question of abortion and will undoubtedly be played out in future court decisions. Whether the Roe decision was illegitimate judicial activism depends on whether one sides with Robert Bork or Laurence Tribe.[5] One conservative justice, Lewis Powell, appointed by Nixon in 1971 had a somewhat different prospective. His father-in-law was an obstetrician in Richmond, Virginia, and he had two brothers-in-law who were obstetricians. He had "heard the stories of unsanitary butchers and coat-hanger abortions." He felt the right-to-privacy argument was tenuous and based his rationale instead on the opinion of the federal judge who struck down the Connecticut abortion law, viz: "The moral positions on abortion about which each side was so sure must remain a personal judgment, one that people may follow in their personal lives and seek to persuade others to follow, but a judgement they may not impose upon others by force of law."[6] To test the strength of this opinion, we might look at what led up to and has followed the *Roe v Wade* decision.

The pre-Roe period

Condit, in her book on rhetoric and abortion, points out that between 1870 and 1950 up to 30,000 abortions were done "legally" each year in the nation's hospitals. Many more illegal abortions were done outside of hospitals under less than sanitary and safe conditions. In the 1950s and 1960s the number of illegal abortions that showed up in the hospitals as incomplete or septic abortions numbered in the hundreds of thousands. The locus of abortion shifted and by 1971, prior to Roe, up to 600,000 legal abortions were being done each year within hospitals.[7] Many of us had professional if not personal experiences with these events. I went to Harvard Medical School in the late 1940s, when disseminating information on contraception or fitting a diaphragm was illegal in the state of Massachusetts. I learned little about family planning or abortion in those days. I was in residency training in medicine at Columbia-Presbyterian Hospital in New York, and I vividly remember the young woman who died of acute tubular necrosis after a "coat hanger" procedure, steadfastly denying to the end that she had sought an abortion. I shudder a little at the memory of the coroner's post-mortem examination downtown at the Bellevue Hospital morgue. Stories like these, of the death and disability of women from illegal abortion, were beginning to have a public impact.

It took some major events in the 1960s to really engage the general public interest. Sherri Finkbine was a happily married mother of four and the host of the children's television program Romper Room in Phoenix, Arizona. She was pregnant for the fifth time and unwittingly used a tranquilizer picked up by her husband in Europe. It was thalidomide and the gross deformities caused by the drug were by then well known. Ordinarily, she might have had an abortion in her hospital on the grounds of a "psychiatric crisis," but the publicity she created by warning other women created an uproar. The hospital was threatened with suits by religious groups since the Arizona law only allowed abortion to save the woman's life. Sherri Finkbine fled to Sweden where, as Ms. Condit describes: "A deformed fetus was scraped from the womb of this 'all American' woman." This tragic case challenged the prevailing ideas of who needed abortions and why and openly challenged the legal system. Mrs. Finkbine loved children and worked with them. In fact she had a normal child 2 years later. During this same period amniocentesis and prenatal diagnosis became clinical realities and consideration of abortion for fetal indications was born.[7]

The other major event of the 1960s was the rubella epidemic of 1964 and 1965 chronicled in an edition of *Life* magazine. I was a new and young professor and Chairman of Obstetrics and Gynecology at MacDonald House and Western Reserve University in Cleveland. Any prior ideas I had about abortion were lost in the deluge of demands for pregnancy terminations for rubella-induced fetal deformity. The requests were coming from all segments of society and all religious persuasions. Some of my colleagues tried to refer patients from Mississippi and the Dakotas. Although the law in Ohio forbade abortions except to protect the woman's life, at that time I told the hospital trustees that we could no longer use the ploy of a threatened suicide and a psychiatric certification for the abortion. The public debate on abortion was in a sense officially opened. The American Law Institute, composed of academicians and practicing attorneys from the major cities, was circulating its 1959 proposed revision of the model penal code. They suggested the now widely accepted "hard" justifications for abortion: to protect the woman's life or when pregnancy would gravely affect her physical or mental health or when the child would be born with defects or was the result of rape or incest. They recommended that two other doctors provide certification.[5] This proposal was ahead of its time, but no one could expect that the Supreme Court would in a little over one decade go beyond these conservative guidelines.

The events of the 1960s prompted the convening of an International Conference on Abortion in Washington, D.C., in 1967, organized by Eunice and Sargent Shriver and sponsored by the Kennedy Foundation and the Harvard Divinity School. All the "important" constitutional lawyers and sociologists and ethicists and physicians were there. Father Robert Drinan, the future congressman but then Dean of Boston College Law School, felt it would be better to have no laws on abortion like those promulgated by the American Law Institute than to sanction the procedure by law. The ethics debate centered around the balance of values between the interests of the pregnant woman and those of the fetus. In asserting the humanity of the fetus, Paul Ramsey, the conservative Protestant theologian, believed the fetal soul enters the "body" at conception but observed that an abortifacient pill would make abortion a "private" matter. John Noonan presented his history of the attitude of the Catholic Church to abortion, which varied depending on whether quickening was considered the time of ensoulment and even whether the time varied between male and female fetuses. Later he would write that the Church was always against abortion. I wrote: "Even though a pregnancy may not be life threatening, it may be life-devastating enough to force women to desperately seek and obtain abortion by any means possible even at considerable risk to their life. Living with children in poverty, sustaining a pattern of futility of life, living with a hopelessly deformed or retarded child or bearing an illegitimate one without paternal support is a life situation many women will not accept. This is a medical and social fact, moral, legal, and religious issues notwithstanding." I also noted that abortion only interrupts an acute episode of what may be a more chronic or recurrent problem, be it social behavior, poverty, or mental illness. Other forms of therapy are needed to prevent unwanted pregnancy by exercise of personal responsibility and use of contraception. The report of this conference was never published but rather condensed, slanted away from a strong pro-reform consensus, and popularized in the form of a paperback book with a pro-life preface by Pearl Buck.[8] Still and all, this was a civilized conference on abortion in which the discussants appeared to be communicating with one another, but no new ground was broken.

I have always maintained that the reason the ethical debate about abortion is so intractable is because we lack a compelling analogy with other moral conflicts for which reasonable solutions have been devised. The fetus is in and of the pregnant woman. How can society force her to use her body against her will for purposes of gestation when there is no other, even close example of such a requirement for men or for women in other circumstances even to save a life. An apt negative analogy of this is the failure of society to force a father or mother to donate an organ for a needy child. In most instances pregnancy is a greater burden than a bone marrow transplant is. In point of fact, the law does not require that dead persons yield up their organs to save a life without permission. "A Defense of Abortion,"[9] written by Massachusetts Institute of Technology philosopher Judith Jarvis Thomson in 1971, tried to conjure up the imagery of an analogy to abortion. You have been chosen by the Society of Music Lovers because of a compatible blood type to be abducted, drugged, and forcibly connected to the circulatory system of a famous violinist who is dying of kidney disease so that his system can be dialyzed. You wake up and are told that it's unfortunate that this has happened to you but if you unplug yourself the poor violinist will die. This is a balancing act between your right to use your body as you see fit and another's right to life. Your plight poses the question of whether you are morally obligated to carry such a burden and at least raises the symmetry of cases in which a woman is pregnant as the result of being raped. Since the Thomson argument might justify abortion for a viable fetus and doesn't address the issue of when a woman voluntarily puts herself at risk of pregnancy, it fails to carry the day. Abortion politics continued to reflect this conflict be-

tween a woman's choice and the fetus' right to life, but in the post-Roe era the pro-life and pro-choice movements plummeted headlong into two opposing, entrenched camps of ideology.

The post-Roe era

After the *Roe v Wade* decision there were many pro-life-sponsored attempts, most unsuccessful, in the Congress and in the state legislatures to limit access to abortions in various ways. In 1976 the Supreme Court quickly rejected a Missouri statute requiring spousal consent for a first-trimester abortion. Other state statutes including imposing criminal liabilities on physicians to ensure special duties to the possibly viable fetus, limitation on abortion techniques such as saline infusion, restriction of where procedures could be performed to hospitals only, zoning exclusions of abortion clinics, mandating the presence of two physicians in late abortions, the need to provide physical descriptions of fetal development to the pregnant woman, and the requirement for pathologic tissue analysis in all abortions were all ultimately declared unconstitutional. In *Bellotti v Baird* the Supreme Court struck down the requirement for parental consent for minor women. On the other hand, in *Maher v Roe,* the Supreme Court ruled that Connecticut did not need to fund a nontherapeutic abortion with public funds. In 1980, with the *Harris v McRae* decision, the Hyde Bill, which allowed use of Medicaid funds for abortion only if the mother's life was in jeopardy or when the pregnancy was the result of rape or incest, was declared constitutional. Although women had a constitutional right to abortion, the government did not have to fund them. In these two judgments, the foes of abortion scored their first major successes. Constitutional amendments had also been proposed in order to apply personhood to the unborn from conception but never generated sufficient momentum. In 1981, Senator Helms' Human Life Bill defining persons as existing from conception for the purposes of constitutional protection was defeated. In 1983, the proposed Hatch amendment asserting that "A right to abortion is not secured by the Constitution" was also defeated by the Senate.[5]

Ronald Reagan, fortieth President of the United States, may leave his mark in history for his impact on the abortion question. He appointed three conservative justices to the Supreme Court, Sandra Day O'Connor, Antonin Scalia, and Anthony Kennedy, replacing three who voted for the *Roe v Wade* decision, and elevated a Roe opponent, William Rehnquist, to Chief Justice. Reagan openly encouraged and supported a human life amendment and legislative efforts to discourage abortions. The centerpiece of this effort was his 1984 essay, "Abortion and the Conscience of the Nation."[10] Reagan made the comparison of the Dred Scott decision of 1857, which took citizenship away from blacks, with the Roe decision, which denied "citizenship" to fetuses. He cast abortion as the moral equivalent of slavery and referred to the book, *Abortion: The Silent Holocaust.* In the introduction to the book containing Reagan's essay, it was noted, as Condit observed, "none too bashfully" that his writing "is a historic document if only because it evokes the moral passion of Abraham Lincoln against slavery."[7] This was part of a pro-life strategy to motivate the activists and win over the religious and "traditional" Americans. Even the lessons of history were cast in a pro-life mode by John Noonan's book, *An Almost Absolute Value in History.* This was an effort to make the antiabortion tradition not only Catholic and Christian but secular as well. In addition to casting abortion as slavery, as holocaust, and as a consistent wrong through all history, the icons were mobilized. These visual symbols included pictures of fetuses, dismembered fetuses, the tiny feet of a 10-week fetus, and concentration camp victims side by side with fetal corpses. The movie *The Silent Scream,* containing a sonogram of an abortion in progress, was widely distributed. A fertilized egg, a blastocyst, an embryo, and a fetus were always described as an unborn baby. The rhetorical effect was potent and powerful and undoubtedly led to more activism and even violence.[7] Abortion clinics were invaded, vandalized, and bombed, and the number of incidents reached more than 100 in 1984.[11, 12] Relatively peaceful demonstrations before the Supreme Court on the Roe anniversaries were replaced by a religious war in Operation Rescue. Operation Rescue, which is unabashedly religious in its rhetoric and ardor, organized pro-life volunteers nationally to disrupt the operations of abortion clinics. Its leaders come from the evangelical Christian sects but it also has Catholic representation.[13] Unfortunately the politicians and the Justice Department have done more to encourage than to dissuade this sometimes violent form of "civil" disobedience. In the invasion of Witchita, Kansas, by Operation Rescue, to disrupt and close down abortion clinics in August 1991, the state governor addressed the Operation Rescue group at a rally. The United States Attorney General sided with them in a challenge to an injunction against blocking clinic access by Federal Judge Patrick Kelly. Judge Kelly even received personal death threats.[14] Pro-life activists do engender death threats to those opposing them, even though their leaders may try to distance themselves from this form of intimidation.

In 1989, the Supreme Court, with the three new Reagan appointees concurring, upheld sharp state limits on abortion for the first time. The case, *Webster v Reproductive Health Services* involved Missouri state laws that banned abortions from public hospitals and banned public employees from performing them unless

the woman's life was at risk. The law further required tests for viability if the fetus was at least 20 weeks' gestation. In the preamble of the Missouri law, it was asserted that life begins at conception, but the Court did not address this. Blackmun, in dissent, noted the religious rather than secular basis for stating that life begins at conception and felt it violated the Establishment Clause of the First Amendment separating church and state.[15] The extreme interest in this case was evidenced by the fact that more amicus curiae briefs were filed for Webster than in any prior Supreme Court case.[5] The assault on Roe had begun in earnest, and many felt this was an invitation for the states to enact laws that could be used to test complete reversal. This was also an invitation for political activism on this issue at the state legislative level. There was a sense that we were returning to one-issue politics.

Further partisanship by the federal executive branch under President Bush is reflected in the Department of Health and Human Services "gag rule," which limits what providers in federally funded Title X contraceptive clinics can say about abortion, which is nothing, except that it is not a form of family planning. In the 1991 *Rust v Sullivan* decision the Supreme Court upheld this as constitutional.[16] This intrusion of government into control of speech by a physician to a patient should bother all physicians regardless of how they feel about abortion.

The public and the polls

Public opinion polls have been used extensively since the Roe decision. The problem, according to sociologists, is that polls may make rather than mirror public opinion; they always slant questions and oversimplify the diversity of society. In any case, during the past 15 years some results are consistent and unchanging. Some 20% of Americans oppose abortion on essentially all grounds, 20% approve abortions without restriction, and the majority approve abortions under limited and specified conditions. The "hard" justifications for abortion—protecting life, physical health, severe deformity of the fetus, and rape and incest—generally have a substantial majority supporting them.[17] While most Americans do not want to make abortion illegal, sizable numbers respond yes when asked if abortion is murder.[18] There is also a greater willingness to countenance early rather than late abortions. The major arguments are against abortion on demand, as birth control, or for convenience, sex selection, or social reasons. Some see hope of compromise around the selective limitation of abortion, but the activists on both sides have shown little "give." Mary Ann Glendon[19] of Harvard Law School has suggested we should be more like the French, have restrictive abortion laws and then get around them in some way.

Kristen Luker has studied the activists and found the pro-life group spending more time at it; they are more apt to be blue collar, married housewife-mothers, high school graduates, Catholic or religious, and male professionals. The pro-choice group are more apt to be white collar, unmarried professional or working women, often without children, college graduates, and not regularly attending church.[20] Often personal experiences are the motivation for activism. Kate Michelman, Executive Director of the National Abortion Rights Action League, tells the story of expecting her fourth child when her husband, who had fallen in love with another woman, asked for a divorce. When Michelman requested an abortion, the hospital panel told her she could have the procedure if the husband who had just abandoned her would give his consent. Not surprisingly, Ms. Michelman thinks women themselves ought to make this decision.[5, 21] There is the story of Becky Bell who was afraid to tell her parents about her pregnancy, took a home abortifacient, and died. Her father became an activist to quash consent laws that require parental notification.[3]

Ethics and religion

In the United States in the late 1980s half of all pregnancies are unintended (3.4 million) and roughly half of these are aborted (1.6 million). More than half of the unintended pregnancies occur in women who don't use contraception, which dramatically reflects the potential impact of family planning education on the abortion numbers. Those seeking abortion are generally under age 25, unmarried, economically deprived, and either in school, working, or both.[22] In the book *Pregnant by Mistake* by Maxtone-Graham,[23] women with unwanted pregnancies were interviewed. They generally break down into three categories. The first group of women used birth control responsibly, knew beforehand that they would seek an abortion if contraceptives failed, and did not act out of emotion or impulse at the time of the unwanted pregnancy. These women were acting in a "moral" way according to the reviewer, and even if someone disagreed with their rationale, one would be hard put to challenge their moral intentions. Another set of women were self-characterized as being psychologically "messed up" with traumatic personal histories to match. The reviewer felt that berating them for immorality would be a futile exercise. A third group was described as young, naive, and incapable of dealing with the world in a morally functional way.

Those women who could discuss their moral principles felt that using contraceptives, being consistent in their attitude about unwanted pregnancy, and considering the interest of others constituted a rational moral defense for their actions. Some felt that having a child should require more justification than having an abortion. They did not want to bear a child in the absence of a loving, stable environment. Bearing a child and

then giving it up for adoption was considered by many women to be cruel. Some women bore their first child and gave it up for adoption because they didn't know of the abortion option. In a second pregnancy they chose abortion. As one woman expressed it, "Carrying a pregnancy to term is different from abortion, those months of carrying the child were very destructive to me. That was the end of my trust in people." Most of these women resented the male domination of the abortion debate and the limits drawn up by the law, medicine, and the church, with insufficient input from women. They also resented the implication that if you voluntarily have sex, you must accept the responsibility for bearing and raising any child that ensues even it it is a failure of contraception. These women looked on sex as an inevitability of life, like eating. While each act of sex, like each meal, might be voluntary, eating and having sex over a lifetime are not voluntary in any practical sense of the word.[7]

What I have ascertained in these women's experiences is a form of descriptive ethics that is all too often neglected by the ethicists, who tell people how to live their lives from the perspective of applied or normative ethics without knowing what those lives are really like. A good deal of the ethical debate has centered on the right of the fetus to life having greater moral force than any woman's need, save direct threats to her life or physical health. The pro-life support for life, a human being, a person, or whatever to exist at conception is, in my view, an attempt to secularize what is largely a religious issue, the sanctity of the reproductive act and anything that ensues from it. There is an attempt thereby to deny any morally relevant differences between a fertilized egg, a preembryo, an embryo, a fetus, and a newborn infant at term and to morally trump any but the strictest justifications for abortion. I will grant that after a stage of development that would allow viability outside the womb, one is hard-pressed to find morally relevant differences between the advanced-stage fetus and the newborn, but there are such differences. These differences diminish as term approaches but never disappear; witness the caution with which the law now deals with treatment decisions that might violate the pregnant woman's wishes. That caution is engendered by the fact that the fetus is inside the woman's body. In this conflict between the supposed absolute right of the fetus to be born and the woman to use her body as she chooses, one must recognize that fetal life is contingent life. It is contingent on normal development, which is by no means certain in nature (there is a 60% attrition rate), and it is contingent on invading and using the woman's body for its development. Those contingencies are the morally relevant differences. The right of a woman to the use of her body as she chooses cannot be overcome in early pregnancy by any secular argument that contingent fetal life has some superior claim. If one invokes souls and the sanctity of contingent fetal life, one can make an argument in favor of the fetus that is religiously grounded and morally defensible but not in a pluralistic democracy. Stronger arguments of a secular nature can be made for limiting abortions after viability is reached, but for my part I do not want to defend late abortions at all. After viability, one of the contingencies of fetal life is removed, and if the pregnancy must be terminated, it can be with the expectation of treating the fetus as a premature newborn when delivered. Independent life begins at birth; there is no secular or scientific justification for believing otherwise. Equating contingent fetal life with independence is a rhetorical device that contributes to lack of respect due the moral views of those who disagree and foments the kind of religious fervor seen in Wichita in the hot summer of 1991.

Not all religious views hold that abortion is always wrong or that life begins with conception. There is no mention of abortion in the Bible. One passage in Exodus 21:22, 23 (NAS) stipulates that "If men struggle with each other and strike a woman with child so that she has a miscarriage, yet there is no further injury, he shall be fined as the woman's husband may demand of him; and he shall pay as the judges decide. But if there is any further injury than you shall appoint as penalty life for life." Clearly the woman's life carries greater weight than the miscarriage. Note also that the husband (not the woman) sets the fine in the male tradition that miscarriage deprived the father of an heir.

I want to close with some quotes from a sermon on abortion given by a minister in a Southern Baptist Church in Waco, Texas.[24] It is the most eloquent and wise reading I have seen on the subject.

"Thousands of years of debate . . . and still there is no consensus about when human life becomes a human person. Despite the efforts of movies like *The Silent Scream,* no scientific information can yet determine when unborn life becomes a human person. Just as medical science has never absolutely, clearly and without an ounce of reservation been able to determine when a dying person loses personhood, science cannot tell us with absolute clarity when personhood begins.

"But neither has the church formed a consensus on the question . . . . One of the reasons for this lack of consensus is that the Bible has no clear word. I repeat, there is no place in the Bible where it said: 'Thou shalt not have an abortion.'

"The primary Jewish position is that human personhood begins when the baby is born and draws breath. Genesis 2:7 declares that 'God breathed into his nostrils the breath of life and man became a living soul.' Elsewhere there is a place in Old Testament law *(noted above)* . . . .

"The Roman Catholic Church has held its very clear position only since 1869 and Pope Pius IX. It has always been against the abortion of a human being . . . .

"Protestant groups have taken a whole range of positions . . . . Thus we must invoke the Protestant principle which says that in cases where Scripture is not clear, final interpretation should be left to each individual person, given guidance within his or her community of faith.

"We must be very careful in even mentioning God's will. We cannot glibly claim God's will is involved in every conception, I cannot ascribe to God's will conception by rape or by incest or by a couple in no position to marry and parent a child. These are all occurrences in a tragic and sinful world. Thus, abortion is not the automatic breaking of God's will. Neither can we say that it is God's will that we perform abortion . . .. He understands—even allows—and certainly forgives the choices we have to make.

"And the Church's role? It is to guide in the decision-making process by doing what I'm doing: safeguarding the woman's freedom of religion to make the choice; to affirm her in her willingness to bear a child under difficult circumstances if that is her choice; and if she decides instead to have an abortion, not to tell her what she should be feeling. Instead:

> if she feels guilt, to offer and act out the Grace of God
>
> if she feels grief, to offer and act out the Comfort of God
>
> if she feels remorse, to offer and act out the Peace of God
>
> if she feels fear, to offer and act out the Love of God . . . .

"Since there is no moral consensus or biblical mandate we should accord women the legal, moral, and religious freedom to choose.

"This sermon is an interim report, influenced by the thinking of others, and struggled with at a personal level by one who does not have all the answers. It is the best I can do, for now. I say it with apprehension and some sadness. It is as clear as I can think, and no clearer—it is as simple as I can speak, but no simpler. May God have grace and understanding for women who must make such decisions—and for preachers who talk about it."[1, 24]*

To this, I can only add amen! I included the material on ethics and religion in this last section to try to make the point that there is more than one morally and religiously respectable position on abortion. We should vigorously oppose the moral self-righteousness of any extreme position for or against abortion and help fashion a public policy that does justice to our democratic principles.

Contraceptive prevalence, reproductive health, and international morality

Egon Diczfalusy, MD, PhD
Stockholm, Sweden

William Faulkner said that the past is never dead; it is not even past. On the 18th of September, 1888, the first paper at the first meeting of the American Association of Obstetricians and Gynecologists was delivered by Joseph Price, in Philadelphia, Pennsylvania. The paper was entitled "Drainage in Abdominal Surgery."

In 1927, Professor James Kennedy, a student, an admirer and a successor of Joseph Price, established the Joseph Price Oration with a visionary move to enhance communication with scientists from abroad. The first Joseph Price Oration was given in 1928 by Professor Alfred Scott Warthin, Ann Arbor, Michigan, on "Sex Differences in the Pathologic Picture of Syphilis." I will deliver the fifty-eighth Joseph Price Oration, and the occasion fills me with pride and humbleness.

I have read with admiration the curriculum vitae of Drs. Price and Kennedy. Had I been asked to provide a common epitaph for both of them, I would have selected the words of François de Sales: "*Le bruit ne fait pas de bien, le bien ne fait pas de bruit.*" In English this would mean that the noise doesn't do any good, the good doesn't make any noise. I would like to pay tribute to the memory of two giants in the history of American obstetrics and gynecology.

There is an Oriental proverb saying that when a man is young, he writes songs; grown up, he speaks in proverbs; in old age, he preaches pessimism; and I would like to emphasize that I am not a pessimist. I am not an optimist either; I am simply confused. Why? Because every day I am confronted with three levels of reality: the scientific, the economic, and the political. When those three levels converge, progress can be amazingly rapid. When they don't, which is frequently the case, the political reality assumes a controlling power. This is particularly true in the fields of population, fertility regulation, and reproductive health.

It is generally accepted that at the time Jesus Christ was born the world population was <300 million. It took some 1500 years to double the global population, which occurred around the time of the second voyage of Columbus to America beginning in the sixteenth century. The first billion was reached at the beginning of the nineteenth century amid the turbulence of the Napoleonic wars, and the second billion was reached in 1927 at the very time James Kennedy established the Joseph Price Oration. But now, in <50 years, the population doubled to 4 billion in 1974. The fifth billion was reached in 1987 and the sixth billion is projected to be reached in 1997 or 1998.[1] How did developing country governments react to this development? With concern, as indicated by the fact that in the early 1960s only seven governments provided family planning programs. In the early 1980s more than 120 governments supported such programs.[2] The great increase in the number of governments supporting family planning was accompanied by an impressive rise in contraceptive prevalence worldwide, which was greatly facilitated by breakthroughs in contraceptive technology principally in the United States, exemplified by the development of oral contraceptives and modern intrauterine contraceptive devices. In the early 1960s the contraceptive prevalence in all developing countries was only 9%. In the early 1980s it was 45%.[1]

The initial rationale of developing country governments for supporting family planning programs was undoubtedly the demographic concern. However, the rationale was considerably broadened when those governments recognized that the effective use of family planning would delay the age at first pregnancy and space further births. When integrated into primary health care, both factors will decrease infant, child, and maternal morbidity and mortality and significantly reduce illegal abortions and their health hazards. Hence today it is generally recognized by developing country governments that family planning, maternal care, infant and child care, and the control of sexually transmitted diseases constitute the four fundamental pillars of reproductive health policy.

The United Nations Population Fund estimates that in 1987 the number of contraceptive users worldwide was around 380 million. This corresponds to a contraceptive prevalence of 50% to 51%, which is equivalent

Table I. Contraceptive method used

Method	*Developing countries (%)*	*Developed countries (%)*
Sterilization	45.3	14.2
Intrauterine contraceptive devices	23.1	7.8
Hormonal	15.5	18.4
Natural	8.5	30.5
Barrier	6.6	21.3
Other	0.9	7.8

Source: United Nations Population Fund, 1990.[3]

to a statement that another 380 million or so couples were not using any form of fertility regulation. In terms of the various methods female sterilization was the method in 119 million users, male sterilization in 45 million, intrauterine contraceptive devices in 84 million, steroidal contraceptives in 67 million, and conventional methods (barrier, periodic abstinence, withdrawal, etc.) were used by 65 million couples.[3] There are enormous regional, national, cultural, and social differences in the contraceptive methods used.[4]

The marked differences hidden beyond these figures are shown by the percentile distribution of various methods in developing and developed countries (Table I). Furthermore, marked regional differences exist; in 1983 contraceptive prevalence was 74% in East Asia, 53% in Latin America, but only 14% in Africa. Female and male sterilization and intrauterine contraceptive devices together accounted for 65% of the contraception in East Asia but for only 3% in Africa.[1]

Another important aspect of the problem is unmet contraceptive need, defined as the number of women of fertile age who do not wish to have more children. It is estimated by the United Nations that more than one third of the 140 million women in the developing world who became pregnant in 1988 did not want to have another child.[5]

A major step in the evolution of ideas in the field was the recognition by an increasing number of developing country governments that the demographic perspective of unmet contraceptive need can best be influenced by addressing the user perspective. The user perspective is dictated by three significant precepts: human rights, reproductive health, and family economy. These precepts are inextricably intertwined with the status and development of women. This powerful conceptual development is reflected by the political policy position of developing country governments. In 1980, 52 governments stated that they supported family planning for the demographic rationale, but 65 said that they provide support because of the human rights and reproductive health rationale, whereas 35 governments still did not provide any support.[6]

What is reproductive health, then, and how is it quantitated? The constitution of the World Health Organization in 1948 defined "health" as a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity. Viewed against this broad and very positive definition, reproductive health has a number of basic elements such as the *ability* to procreate, regulate fertility, and enjoy sex; *success* in the outcome of pregnancy and in infant and child survival, growth, and development; and *safety* in pregnancy, childbirth, fertility regulation, and sex.[4] It should be emphasized that in all resolutions of the World Health Assembly (the parliament of the World Health Organization [WHO]) the term fertility regulation also includes the prevention and management of infertility.

Reproductive health is assessed by considering various indicators shown in Table II. It should be stated that the figures in Table II represent only the tip of the iceberg of preventable human suffering.

There is an epigram by Stephen Crane[8]:

A man said to the universe:
"Sir, I exist."
"However," replied the universe, "The fact has not created in me
A sense of obligation."

The question is, has it created a sense of obligation in us? WHO reminds us that 85% of the world's births, 95% of the world's infant deaths, and 99% of the world's maternal deaths take place in developing countries.[9] Indeed, the lifetime risk of dying from pregnancy-related causes is 1 in 1750 in developed countries, 1 in 90 in Latin America, 1 in 38 in South Asia, and 1 in 24 in Africa.[10] The WHO estimates that between now and the end of the century 7 million women will die in childbirth. The majority of maternal deaths in developing countries are preventable through prenatal care, basic health care, and family planning at an estimated cost of a mere $2 per capita per year.[11]

Among the major child-killing diseases in developing countries, diarrhea is responsible for 5 million deaths annually, followed by acute respiratory disease, 4 million; measles, 2 million; tetanus, 1.8 million; and malaria, 1 million. One of the underlying factors is malnutrition. The United Nations estimates that the percentage of malnourished children worldwide is 39%; it is 52% in Southeast Asia, 35% in Africa and in the eastern Mediterranean region, and 21% in Latin America.[5]

The annual total of sexually transmitted infections is 250 million new cases each year, according to the recent estimates of WHO.[11] These figures are shown in Table III. It should be mentioned that hepatitis B can also be transmitted sexually, at least in certain endemic areas.

With respect to human immunodeficiency virus, WHO estimates that since the start of the pandemic >1.5 million cases of acquired immunodeficiency syndrome may have occurred worldwide, about 400,000

of which have been pediatric acquired immunodeficiency syndrome cases resulting from perinatal transmission. On the basis of current projections, WHO has estimated that by the year 2000 there may be a cumulative total of 25 to 30 million human immunodeficiency virus–infected adults and 10 million infected infants and children in the world. It is also estimated that during the 1990s about 10 million uninfected children will be orphaned because of their mother's death from acquired immunodeficiency syndrome.[11]

From the data shown here, it is easy to define our goals in reproductive health. It will be much more difficult to realize them. The goals are to reduce the unmet need for family planning, to increase family planning services and methods, to lessen maternal infant and child mortality and morbidity, and to reduce the prevalence of sexually transmitted diseases.

All this will require money, money, and money. As George Bernard Shaw said, "Money is indeed the most important thing in the world, and all sound and successful personal and national morality should have this fact for its basis." (George Bernard Shaw: *The Irrational Knot*). I would like to go a step further and suggest that this must also be the basis of international morality, as suggested by the title of this oration.

Dr. H. Nakajima, the Director General of WHO, recently said that in the developed world annual per capita health expenditure averages $400, whereas in the poorest countries and the least developed countries it is <$5. The missing ingredient, says Dr. H. Nakajima, is the will to help. If we could increase health spending in the developing countries by only $2 per capita, we could immunize all their children, eradicate polio, and provide the drugs to cure all the cases of diarrheal disease, acute respiratory infection, tuberculosis, malaria, schistosomiasis, and sexually transmitted diseases. I may add to this that between 1980 and 2000 the total population of the developing world is expected to increase by 95%, whereas the elderly population (aged ≥65) will probably rise by almost 240%.[12] This will result in an enormous rise in health costs, actualizing the questions raised about both international and national morality. The champions of national morality may wish to have a glance at the figures of Table IV taken from the data published by the World Bank.[13]

The message is straightforward; irrespective of their economic standard, governments spend much more money on defense than on health. Governments always provide justification for this, which is the behavior of other governments, but by the end of the day this philosophy might be suicidal.

Where do we go from here? What about our common future? Walt Whitman stated in 1856 that "the future is no more uncertain than the present" but, of course, he was not a demographer. The United Nations points out that yearly increments of the world population over the next decade will approach 97 million; 94% of them will be born in the developing world. Hence by the end of the century global population will increase by another billion, equivalent to the total world population at the beginning of the 19th century. But then? Will the growth ever come to an end? Yes, it will; all demographers agree that the world population will stabilize at the end of the next century. However, whether the plateau will be at 8, 10, or 14 (or more) billion people will largely depend on the number of years it will take to reach the replacement level of fertility worldwide, which is approximately 2.1 children per couple. If the replacement level of fertility is reached in 2010, global population will stabilize at about 8 billion by 2060. This is the United Nations' low projection from 1982 and very few people believe it to be realistic. If replacement level is reached in 2035, population will stabilize at 10 billion by 2095; this is the median projection that is used by most specialized agencies of the United Nations in their projections. However, if the rate is reached only in 2065, global population in 2100 will exceed 14 billion.[14]

Two remarks may be appropriate in this connection. The first is that these figures are demographic projections, and demographic projections are neither forecasts nor destiny. What they show is the most likely course of events, provided certain basic ("standard" or

Table II. Indicators of reproductive health

Category	*Millions (worldwide)*
No access to fertility regulation	400
Infertile couples	60-80
Induced abortions (yearly)	30-50
Maternal mortality (yearly)	0.5
Maternal morbidity (yearly)	25
Infants with low birth weight	20
Infant mortality (yearly)	4
Child mortality (1-5 yearly)	9
Sexually transmitted diseases (new cases yearly)	250

Source: United Nations and World Health Organization estimates, 1988 and 1990.[4]

Table III. Annual total of sexually transmitted diseases (new cases in 1990)

Disease	*New cases (millions)*
Trichomoniasis	120
Genital chlamydia	50
Genital papillomavirus	30
Gonorrhea	25
Genital herpes	20
Syphilis	3.5
Chancroid	2.0
Human immunodeficiency virus	1.0

"critical") assumptions are fulfilled. The projections of the United Nations and also those of the World Bank are based on two such assumptions, namely, that mortality will continue to fall everywhere until life expectancy for women is 82 years and that fertility will eventually reach and stay at replacement levels everywhere. The other point is that in determinig the ultimate size of world population, fertility matters much more than mortality. Hence, if the decline in fertility is slower than expected, the projections of the ultimate size of world population may require a revision. Indeed, the United Nations Population Fund recently warned that if the current trends do not decrease, the medium estimate of 10.2 billion is likely to increase to 11.3 billion.

That the future is more uncertain than the present is evidenced by the most recent revision of the United Nations Population Division's world population projections for the year 2100. The latest medium projection is 11.2 billion, medium-high 17.6 billion, and medium-low 6.4 billion.[15]

In view of these and other considerations, I am deeply convinced that contraceptive prevalence is the key, not only to demographic development but also to improved reproductive and environmental health and to brighter economic and social development. That this is really the case is convincingly indicated by the studies conducted by Bongaarts et al.[16] of the Population Council in 96 countries. Those studies revealed a highly significant correlation between the total fertility rate (or, as a close approximation, the number of births per woman) and contraceptive prevalence. To every 10% increase in contraceptive prevalence, there is a corresponding decrease in fertility rate by 0.7.[1, 16]

The United Nations medium variant projection (with an ultimate population size of 10 billion or so) would therefore necessitate a decline of the current total fertility rate in developing countries (3.6 to 3.7) to a rate of 3.0 between the years 2000 and 2005 and to 2.4 between 2020 and 2025, which in turn will require an increase in contraceptive prevalence to 58% and 71%, respectively. In absolute numbers this would mean an increase in contraceptive users worldwide from the present 380 million couples to approximately 500 million by the year 2000, 650 million by the year 2010, and almost 900 million by 2025.[1, 4]

This is, of course, a big order and the first question is, is it feasible at all? Yes, it is, provided there is the political commitment and basic willingness of the population. Meanwhile, it took 58 years in the United States for fertility to decline from a rate of 6.0 to 3.5 (between 1842 and 1900); it took only 8 years in Thailand (between 1969 and 1977), thanks to the availability of modern technology, political will, and a genuine desire of the population to reduce family size.

What will it take to reach the big objective, the medium projection? First of all, money. The present yearly expenditure worldwide is around $4 billion, the major part of which is covered by a number of developing country governments, i.e., China, India, and Indonesia. It is estimated that the provision of family planning for half a billion couples by the year 2000 will incur a yearly cost between 8.4 and 11.4 billion dollars[3] and the $64,000 question is, who will provide the money? WHO reminds us that 80% of the world's gross domestic product is provided by a dozen countries, whereas 101 developing countries have readjustment programs and their per capita income today is much less than 10 to 15 years ago. However, the Development Assistance Committee of the 18 "rich" countries of Organization for Economic Cooperation and Development disburses some 48 billion dollars each year for official development assistance; that's where the money is.[17] Unfortunately, of the total donor development aid from industrialized nations to developing countries, only 1.3% goes for family planning. Why? Because there are no requests submitted by developing country governments. Why not? Because their political leaders receive one type of message from us and an entirely different type of message from some of our political and religious leaders. As the famous medicine man of the Kaiapo Indians of the Amazonas, Beptopup, said in an interview, "I am too old to understand the white man." Uncle Beptopup, you are not the only one.

Lack of money and lack of political commitment are important barriers to a rapid increase in contraceptive prevalence, but there are also others. The involvement of community leaders is as important as that of the central government. The root of the success of the Indonesian family planning program is the wholehearted support by religious leaders and traditional birth at-

tendants at the community level. Other important barriers may be cultural, educational, geographic (too long a distance to the nearest health center), or financial (too expensive for the family), or reasons related to the delivery of services or the scarcity of the available methods.[5]

Someone said that there has never been a generation that knew so much about man and so little about human nature. Therefore policy and sociobehavioral research in contraception and reproductive health are crucial, because "the effectiveness of any technology is shaped as much by the user as by the technology itself."[18]

Education is of paramount importance; in 1984 the World Fertility Survey demonstrated in the developing countries a significant correlation between the current use of efficient methods of contraception and the number of years of education.[19] The importance of these studies is underlined by a recent report from the United Nations Educational, Scientific, and Cultural Organization (Paris, 1988), indicating an illiteracy rate among women aged ≥15 of 48.9% in all developing countries and 78% in the 42 least-developed countries. The rate is 47.4% among Asian women and 64.5% among African women.[20] It is easy to see that there is a correlation between education and status of women. The WHO points out that one third of the households of the world are headed by women, and women constitute one third of the world's labor force. However, women are responsible for nearly two thirds of the total hours worked, receive only 10% of the world's income, and own <1% of its property.[9]

Another problem is the image of a "population mafia." A visitor to a rural health center may sometimes notice that a large variety of contraceptive drugs and devices are provided, but the simplest lifesaving materials and drugs are not available. The local population perceives this as a sign of conspiracy, whereas the simple truth is that contraceptives are provided by the development assistance agencies and essential drugs and materials should be provided by the national or regional government, but they are not.

Ready and easy access is also an important factor. Estimates for 1982 suggest that only in about 40% of developing countries does as much as half the national population have ready and easy access to some form of modern contraception.[1] In this context ready and easy access is defined as it should not take more than 2 hours per month and 1% of the monthly income of the family to obtain a month's supply of contraceptives.

The quality of family planning services also has a great significance. The best services are those that are integrated with maternal and child health care. The training and commitment of personnel are crucial for adequate counseling. Furthermore, there must be an adequate referral system and also a good follow-up system. Many developing countries are a long way from establishing an adequate service delivery.

A few words must be said about contraceptive development. What happens in the field? The need is increasing and the number and activities of the "actors" are decreasing. That contraceptive choice is too limited today is suggested by the outbreak of unwanted pregnancies among adolescents in many countries, by the high prevalence of induced abortions, and by the increasing reliance on sterilization, carried out at younger and younger ages. A greater variety of contraceptive methods is needed. What happens, however, is a significant reduction in contraceptive research and development. Carl Djerassi[21] points out that in 1970 there were 13 major pharmaceutical companies that conducted contraceptive research and development. By 1987 the number had dropped to four. Djerassi also stated that among the reasons for the retrenchment indicated by industrial leaders are factors like the especially expensive toxicologic requirements, the poor public image of the field caused by negative publicity, the fear of litigation, and the unavailability of insurance. In view of this development, the National Research Council in Washington warned in 1990 that "unless steps are taken to change public policy related to contraceptive development, contraceptive choice in the next century will not be appreciably different from what it is today."[22]

In an attempt to try to compensate at least in part for the diminishing industrial activities, in the 1970s a number of international and national contraceptive development programs were initiated, such as the Special Program of Research on Human Reproduction of the WHO, the Contraceptive Development Branch of the National Institute of Child Health and Human Development, the Population Council's International Committee on Contraceptive Research, Family Health International, The Contraceptive Research and Development Program (CONRAD), and the Program of the Indian Council of Medical Research (ICMR). All these programs are very cost-effective and show impressive achievements. However, in 1980 to 1983 their pooled yearly expenditure on contraceptive development was only around $25 million[23] whereas the industry's estimates for the cost of developing a new chemical entity into a drug are between $270 and $360 million.[24]

This brings us back to our starting point, the three different levels of reality—scientific, economic, and political. The World Commission on Environment and Development quotes Professor P. Lindbloom of the International Academy of Engineering, saying "the problems of today do not come with a tag marked energy, economy, or carbon dioxide or demography, nor with a label indicating a country or region. The prob-

lems are multidisciplinary and transnational or global. The problems are not primarily scientific and technical. In science we have the knowledge and in technology, the tools. The problems are basically political, economical and cultural."[25]

Almost 200 years ago, the second President of the United States, John Adams, wrote that, "Meanwhile all other sciences progressed, the art of governing did not develop. Its exercise today is hardly better than it was 3,000 or 4,000 years ago." This may not be valid today, at least not for all governments, but we are facing another, major political problem because global problems would require global solutions, which in turn would necessitate efficient global mechanisms. It is clear, however, as Jean Monnet said in his autobiography, that "the sovereign nations of the past can no longer solve the problems of the present. They cannot ensure their own progress or control their own future." Why not? Because "the traditional forms of nation sovereignty are increasingly challenged by the realities of ecological and economical interdependence.[25] And, whatever happens in organizational terms with our global reality, it seems to me obvious that sustaining a global population of 14 billion human beings or more will require a very high level of technical civilization and, an intimately interconnected world economy. As Adlai Stevenson hoped, there should be a general recognition that "our needs for our fellow men and women far outweigh our arguments with them."

In the 1970s there was a symposium entitled "Can We Survive Our Future?"[26] The answer is that of course we can. There is a real future for man and, as Jawaharlal Nehru said, the future belongs to science.[27] The future is created in the minds of the new generation of scientists and that future is truly international. However, to see the real impact of science, one needs a broad historic perspective. In 1944 Winston Churchill said that "the longer you can look back, the further you can look forward."[28] R.L. Lesher and G.J. Howick, in a National Aeronautics and Space Administration report in 1966, look back 50,000 years. They stated that "800 life spans can bridge more than 50,000 years; but of these 800 people, 650 would have spent their lives in caves or worse. Only the last 70 had any truly effective means of communicating with one another, and only the last six ever saw a printed word. Only the last four could measure time with any precision and only the last two used an electric motor; the vast majority of the items that make up our material world were developed within the life span of the eight hundredth person."[29]

All of us could add a highly significant milestone to that list, be it telephone, television, computer revolution, landing on the moon—there is no end to it. One may also reflect on the fact that at least 90% of the drugs featured in our daily prescriptions were developed by the eight hundredth person. Indeed, in 1977, Henderson remarked that "somewhere between 1910 and 1912 in this country . . . a random patient with a random disease consulting a doctor chosen at random had for the first time in history of mankind, a better than 50-50 chance of profiting from the encounter." So why do we despair? There is a future for man and that future is called science.

However, we must go a step further. There is a classical Latin quotation, *tempora mutantur, nos et mutamur in illis,* meaning that times change and we change with them, attributed to Emperor Lothar I of the ninth century. The problem with this quotation is that it is true with one qualification—we don't change with the same speed. The changes around us are accelerating so rapidly that our perception of these changes and of their consequences is lagging behind. In the final analysis, all of us are prisoners of our perceptions, watching shadows on the walls of Plato's cave; therefore people's perceptions of reality may have a controlling influence on the future of the human race. To a scientist, many of those perceptions are utterly naive or even dangerous. At a meeting of Nobel laureates convened by President Mitterrand to celebrate the bicentennial of the French revolution, Elie Wiesel said the following: "Scientists have provided mankind with the means of destruction. It is up to them now to find the means for saving mankind." Great! And what will the other 5.3 billion human beings do? Wait and see?

I see a monumental challenge, to be faced by the international scientific community and by every single physician, for that matter: to try to change the perception of priorities and their consequences by the people and their governments. Can it be done? Yes, it can, but it will require more effort than to discover the brave new world in the outer spaces of the universe. Why? Because, as Werner Heisenberg said in 1971, "Reason is a very limited faculty of the human mind." If so, can it be done at all? Yes, it can, because reason is a limited faculty, not an absent faculty of the mind. Therefore a very great global effort is needed.

What should be our message? I would like to suggest one—telling people of the world that fundamentalism and obscurantism will not improve the quality of life for future generations; only science and technology have proved the ability to do so. Why is it so? Because, as Peter Drucker[31] said "We don't know the answers but we know the issues." And I would like to add that we also know which issues are researchable and how.

My last remark, if I may say this, is: In the final analysis hope is the quintessence of the human condition. Therefore it is crucial to generate fresh hope

among young scientists and to stimulate and support their efforts in the acquisition, systematization, and dissemination of positive knowledge, which is the key to a brighter future.

I started with a quotation from William Faulkner. Let me close with another of his sayings:

> I decline to accept the end of man . . .
> I believe that man will not merely endure;
> He will prevail . . . .

Evidence of embryo- and trophoblast-toxic cellular immune response(s) in women with recurrent spontaneous abortion

Joseph A. Hill, MD, Katalin Polgar, PhD, Bernard L. Harlow, PhD, and Deborah J. Anderson, PhD

Boston, Massachusetts

OBJECTIVE: The purpose of this study was to determine whether reproductive antigens stimulate lymphocytes and macrophages from women with recurrent abortion to secrete factors that are toxic to preimplantation embryos or trophoblast cells in vitro.

STUDY DESIGN: Mononuclear cells were isolated from 30 fertile controls and 300 nonpregnant women being evaluated for recurrent abortion. Supernatants generated from these cells after separate culture with sperm and trophoblast antigen extracts were added to two-cell mouse embryo cultures and trophoblast proliferation assays. Toxicity was assumed when the median percentage of embryos developing to blastocysts or trophoblast proliferation was ≤50% of control values. Both parametric and nonparametric statistical methods were used where appropriate.

RESULTS: Mouse embryo development and/or trophoblast proliferation were significantly inhibited by supernatants from trophoblast and/or sperm antigen-activated peripheral blood leukocyte cultures from a majority of 300 women with recurrent abortion but not from 30 women with normal reproductive histories. The mouse blastocyst development assay was more sensitive than the trophoblast proliferation assay in determining toxic factor production. Embryo-toxic factors were produced by activated leukocyte cultures from 90% of 180 women with a history of recurrent abortion of unexplained etiology, whereas trophoblast-inhibitory factors were detected in 50% of women from the same group. The embryo-toxic factor(s) was heat labile, had a molecular weight(s) between 10 and 30 kd, and was absorbed out by passage through affinity columns containing anti–interferon gamma beads.

CONCLUSION: We conclude that recurrent abortion in some women is associated with embryo- and/or trophoblast-toxic factor production in response to stimulation by sperm or trophoblast antigens and that the principal factor may involve the 18 kd, heat-labile, T-lymphocyte cytokine interferon gamma. This study suggests a new cause of recurrent abortion. (AM J OBSTET GYNECOL 1992;166:1044-52.)

Key words: Cellular immune response, embryo, trophoblast, recurrent abortion

Recurrent spontaneous abortion, defined as three or more pregnancy losses before 20 weeks' gestation, occurs in approximately one in 300 pregnancies.[1] Structural chromosomal rearrangements in the couple experiencing recurrent abortion are a well-established cause.[2] Other potential etiologies of recurrent abortion are controversial, although many associations have been made, including anatomic or müllerian anomalies, endocrine disorders, and infections.[3] The cause is unexplained in 40% to 60% of couples.[4,5] Immunologic factors have been implicated in many of these cases.[6]

The cellular immune response to reproductive antigens (i.e., sperm and trophoblast) has been relatively unexplored even though human decidua contains abundant immune cells capable of responding to antigenic stimulation,[7] and many soluble products of activated lymphocytes and macrophages adversely affect embryo development[8] and trophoblast proliferation[9] in vitro. The purpose of this study was to determine whether sperm or trophoblast antigens can stimulate immune cells from women with recurrent abortion to secrete factor(s) that are detrimental to embryo development and trophoblast proliferation in vitro as a possible mechanism for their reproductive failure.

Methods

Study patients. The subjects in this study were 300 reproductive-aged, nonpregnant women undergoing evaluation for recurrent abortion at the Brigham and Women's Hospital Reproductive Endocrinology and Infertility Clinic between July 1, 1986, and June 31, 1989. All subjects were consecutively enrolled and no one refused participation. The women were between 22 and 42 years old and had a history of at least three prior spontaneous abortions with or without a stillbirth,

6/6/35920

ectopic pregnancy, or live birth. These women were grouped by clinical history as follows: women with primary abortion (no live births), women with secondary abortion (abortions subsequent to live births or stillbirths), women with previous ectopic pregnancy, or women with other criteria (abortions interspersed with live births). After a complete medical, surgical, and social history was obtained from the couple and a thorough physical examination was performed on the woman, all couples had peripheral blood chromosome assessment by standard banding techniques. All women underwent hysterosalpingography followed by hysteroscopy-laparoscopy when indicated. Ovulation was assessed by a late-luteal-phase endometrial biopsy with concomitant serum progesterone determination. When the endometrial biopsy specimen was out of phase according to the criteria of Noyes et al.,[10] the suspected ovulation disorder was confirmed by repeating the biopsy in a subsequent cycle. In addition, all women had cervical cultures for mycoplasma and ureaplasma, and blood was obtained for thyroid-stimulating hormone, thyroxine, prolactin, anticardiolipin antibody, and lupus anticoagulant (Russell viper venom time) determinations. Cervical mucus and serum were also obtained for antisperm antibody assessment. After the preceding evaluation, study patients were categorized as having either a genetic, anatomic, endocrine, infectious, or humoral immune cause for their reproductive failure. Peripheral blood was obtained from all women on their initial visit for embryo- and trophoblast-toxic factor(s) testing.

Peripheral blood was also obtained from a comparison group of 30 nonpregnant, paid volunteer women who were randomly selected from the Obstetrical Nursing Service. Women in this control group were of reproductive age (23 to 41) with a history of at least three prior uncomplicated term deliveries and no history of either spontaneous abortion, ectopic pregnancy, or stillbirth. None of the women in the study were taking medication at the time of blood collection.

Embryo- and trophoblast-toxic factor assay

Reproductive antigen preparation. Trophoblast antigen extracts were prepared from the human gestational choriocarcinoma cell lines BeWo and Jeg-3 (American Tissue Type Collection, Bethesda, Md.). These cells were grown in culture flasks by standard culture techniques until confluence. After trypsinization, the cells were washed twice in Hanks' balanced salt solution without calcium or magnesium (Gibco, Grand Island, N.Y.), and cells excluding trypan blue were counted on a hemocytometer (viability always >90%). The cells were diluted to 10^7 cells per milliliter in tissue culture media comprising Roswell Park Memorial Institute 1640 medium (RPMI; Gibco), 10% fetal calf serum, 0.2 mmol/L glutamine, 100 IU/ml benzylpenicillin potassium, and 100 μg/ml streptomycin sulfate (Sigma, St. Louis). Cells were disrupted in a dounce homogenizer, and after centrifugation at 400*g* for 10 minutes, the membrane-enriched trophoblast antigen supernatant was divided into aliquots and stored at −70° C until use.

Semen was obtained from fertile donors by masturbation into sterile containers, and motile sperm were isolated by percoll density gradient centrifugation.[11] Aliquots of 10^7 sperm per milliliter in tissue culture media were dounce homogenized. The suspension was then centrifuged at 400*g* for 10 minutes and the membrane-enriched sperm antigen supernatant was divided into aliquots and stored at −70° C until use.

Supernatant preparation. Mononuclear leukocytes were separated from blood by Ficoll-Hypaque (Pharmacia, Uppsala) centrifugation. Isolated cells were washed twice and resuspended in RPMI medium. Viable mononuclear cells excluding trypan blue were counted on a hemocytometer (viability always >90%) and diluted in tissue culture medium to a concentration of 10^6 cells per milliliter. Leukocyte suspensions were then divided into three 50 ml tissue culture flasks (Becton Dickinson, Lincoln Park, N.J.) containing 10^7 leukocytes per 10 ml of medium in each loosely capped flask. One milliliter of either trophoblast antigen suspension, sperm antigen suspension, or tissue culture medium alone was added to each flask. After a 72-hour incubation at 37° C in 5% carbon dioxide and 95% air, the cell cultures were transferred to separate 15 × 95 mm polystyrene round-bottom tubes with caps (Becton Dickinson) and pelleted by centrifugation at 400*g* for 10 minutes. The cells were next washed once in RPMI medium and once in Whitten's medium[12] and then resuspended in 1 ml of Whitten's medium supplemented with antibiotic-antimycotic solution (Gibco) that had been previously passed through a 0.45 μm filter (Corning Glass, Corning, N.Y.). The pH of the medium was adjusted before use to 7.3 with carbon dioxide gas and supplemented with 0.3% bovine serum albumin (Miles Scientific, Naperville, Ill.). After an additional 12-hour incubation at 37° C in 5% carbon dioxide and 95% air, the three suspensions from each original sample were centrifuged at 100*g* for 10 minutes. The three supernatants were each filtered through a 0.22 μm Millex-GS filter unit (Millipore, Bedford, Mass.) and stored at −70° C until use.

Embryo development assay. Embryo culture was performed as previously described.[8] Briefly, two-cell embryos were harvested from CD-1 female mice (Charles River, Kingston, Ontario) 44 hours after human chorionic gonadotropin administration. Embryos were cultured in 20 μl drops containing a 1:1 dilution of study supernatant in Whitten's medium–0.3% bovine serum albumin under carbon dioxide–equilibrated paraffin oil in Falcon tissue culture dishes (Becton Dickinson). Media and supernatants were equilibrated overnight in

5% carbon dioxide and 95% air before the addition of embryos. Embryos cultured in Whitten's medium–0.3% bovine serum albumin alone served as an additional control. At least 11 embryos were cultured in each 20 μl drop. Embryos were assessed for normal development after 4 days in culture (100 hours after human chorionic gonadotropin administration) by the criteria described by Ducibella.[15] The experimental end point was the percentage of normal blastocysts in each culture after 4 days of development in vitro. The sensitivity and specificity of the assay were maximal when the median percentage of embryos advancing to the blastocyst stage of development was ≤50% of control values. The intraassay and interassay coefficients of variation were 8% and 12%, respectively, for the embryo-toxic bioassay.

Trophoblast proliferation assay. Human gestational choriocarcinoma cells (10^4 cells per 0.1 ml tissue culture medium) were plated in triplicate into 96-well, flat-bottom microtiter trays (Becton Dickinson). Two hours after cell plating, 0.1 ml of leukocyte supernatant or media alone was added (four wells per test solution). After a 2-day incubation at 37° C in 5% carbon dioxide and 95% air, 0.5 μCi of tritiated thymidine (13.1 Ci/mmol; New England Nuclear, Boston) was added to each well. Cells were harvested at 72 hours after trypsinization onto glass fiber filter paper with a MASH II automatic sample harvester (Microbiological Assoc., Los Angeles). Viability of control cultures was assessed before harvesting by means of trypan blue exclusion (viability always >90%). Filter paper disks corresponding to each well were air dried, transferred to scintillation counting vials, and suspended in 2 ml of Betafluor scintillation cocktail (National Diagnostics, Summerville, N.J.). Radioactivity (counts per minute) was measured in a liquid scintillation counter (Beckman Instruments Inc., Fullerton, Calif.) (efficiency of the system 45%), and the mean ± SD of each set of triplicate cultures was calculated. The data are presented as percentages of culture medium control. Trophoblast toxicity was assumed when the median percentage of trophoblast proliferation was ≤50% of control values.

Toxic factor characterization. Trophoblast antigen–stimulated leukocyte supernatants from 15 patients that adversely affected embryo development were subjected to three different methods, to characterize the factor(s) responsible for embryo toxicity: molecular weight dialysis, heat inactivation, and affinity column purification. The supernatants were dialyzed for 12 hours against three changes of Whitten's medium–0.3% bovine serum albumin in Spectrapor membrane tubing (Spectrum Medical Industries, Los Angeles) with molecular weight limits of 3500, 10,000, or 30,000 and then tested in the mouse embryo development assay. In separate experiments aliquots of these supernatants were heat treated at 56° C for 1 hour or passed through an affinity column containing anti–interferon gamma–coated beads (Endogen, Boston) before testing in the mouse embryo development assay. Five leukocyte supernatants not exhibiting an adverse effect and me-

dium alone were used as controls in each of these experiments.

Statistical analysis. We compared the mean age distribution between the 300 women with recurrent abortion and the 30 control subjects with a two-sample *t* test for independent samples and assumed equal or unequal variances based on the F distribution.[14] Differences in mean ages by different categories of abortion and spontaneous abortion causes were assessed through analysis of variance. The percentages of mouse blastocyst development or trophoblast proliferation in supernatants failed the test of normality with the Shapiro-Wilk W statistic[15]; therefore median percentages were compared between the 300 women with recurrent abortion and the 30 controls overall and within each of the categories of abortion and spontaneous abortion causes with the use of nonparametric tests of medians and the Wilcoxon rank sum test.[16] All directional *p* values were two tailed.

Results

Women with recurrent abortion were 80% white, 10% Hispanic, 8% black, 1% Native American, and 1% Asian. The 30 fertile controls consisted of 25 white, 3 Hispanic, and 2 black women. The 300 women evaluated for recurrent abortion had experienced 1367 prior pregnancies, 1213 of which resulted in spontaneous abortion (median 4, range 3 to 25). Fetal loss occurred during the first trimester in 88%, whereas 12% of the abortions occurred during the second trimester (before 17 weeks of gestation).

The control group of women without a history of abortion were slightly older than women with a history of spontaneous abortions (37.5 ± 3.1 vs 35.9 ± 3.4, Table I). Among the 300 women with recurrent abortion, 215 women (72%) had primary abortions, 50 women (17%) had secondary abortions, and the remaining 35 women (11%) could not be identified as having either primary or secondary abortions. Seven of these women had a total of 9 ectopic pregnancies (all tubal gestations), and the other 28 women experienced recurrent abortions interspersed with live births.

The cause of recurrent abortion was unexplained in 180 (60%) women. The remaining 120 women (40%) had recurrent abortion presumably as a result of endocrine abnormalities (17%), anatomic anomalies (10%), infections (5%), humoral immune disturbances (4%), or chromosomal aberrations (5%). There was no correlation between the average age of the women and etiologic categories, except in women with an infectious cause (positive cervical culture for mycoplasma or ureaplasma), who were significantly younger than the other women with a history of spontaneous abortion (32.9 ± 4.1 vs 35.7 ± 1.0, $p < 0.01$).

There was no difference between effects of supernatants derived from unstimulated peripheral blood mononuclear cells from women in any category and control medium in either the embryo development or trophoblast proliferation assays (data not shown). Embryo development and trophoblast proliferation in response to trophoblast antigen–activated leukocyte supernatants and sperm antigen–activated leukocyte supernatants, are shown in Table I. Neither trophoblast antigen–activated nor sperm antigen–activated leu-

ED-T, Embryo development in response to trophoblast antigen–activated leukocyte supernatants; *ED-S*, embryo development in response to sperm antigen–activated leukocyte supernatants; *TP-T*, trophoblast proliferation in response to trophoblast antigen–activated leukocyte supernatants; *TP-S*, trophoblast proliferation in response to sperm antigen–activated leukoctye supernatants.

kocyte supernatants from the 30 fertile women adversely affected embryo development or trophoblast proliferation. Trophoblast and sperm antigen extracts alone had no effect on either embryo development or trophoblast proliferation. Neither race nor ethnicity was associated with either the production of toxic factors or the various causes of recurrent abortion. Both embryo development and trophoblast proliferation in the presence of trophoblast antigen–activated and sperm antigen–activated leukocyte supernatants were decreased in women with recurrent abortion as compared with fertile controls. In the 300 patients with recurrent abortion, embryo development was more often and more severely affected than trophoblast proliferation in the presence of both sperm antigen–activated and trophoblast antigen–activated leukocyte supernatants (effects of trophoblast and sperm antigen–activated leukocyte supernatants on embryo development versus trophoblast proliferation $p < 0.01$). Among the four categories of women with abortions in Table I, embryo development was more adversely affected by trophoblast antigen–activated leukocyte supernatants than by sperm antigen–activated leukocyte supernatants, except in those women with a prior ectopic pregnancy.

Embryo development in the presence of trophoblast antigen–activated or sperm antigen–activated leukocyte supernatants from women with an unknown cause of abortion was significantly less than embryo development in comparable supernatants from women with other causes ($p < 0.01$). Embryo development was also observed to be lower in trophoblast antigen–activated and sperm antigen–activated leukocyte supernatants from women with recurrent abortion caused by an endocrine or humoral immune abnormality ($p < 0.001$) but not in those from the two groups of women with an anatomic or genetic etiology of recurrent abortions. In the two women with antisperm antibodies, embryo development was unaffected by sperm antigen–activated leukocyte supernatants but was adversely affected by trophoblast antigen–activated leukocyte supernatants. However, within the anatomic group embryotoxic factors were produced in women with a diagnosis of endometriosis as their only abnormal finding in response to stimulation by both trophoblast and sperm antigens ($p < 0.05$). In the same group trophoblast proliferation was also significantly inhibited in response to trophoblast antigen–activated leukocyte supernatants from women with endometriosis ($p < 0.05$). A woman with a pericentric inversion of chromosome 9 had low embryo development in response to both trophoblast antigen–activated and sperm antigen–activated leukocyte supernatants and low trophoblast proliferation in response to trophoblast antigen–activated leukocyte supernatants. Otherwise, cytogenetic abnormalities were not associated with either embryo or trophoblast toxicity.

The sensitivity and specificity of the bioassays were greatest when embryo development and trophoblast proliferation were ≤50% of control values (Table II). Only one woman in the fertile control population had a value <50%. This woman had 45% blastocyst development in the presence of supernatant from her sperm antigen–activated leukocyte culture. Using 50% of control values as our cutoff, we detected women with recurrent abortion as follows: for embryo development assays, 63% using trophoblast antigen–activated and 51% using sperm antigen–activated leukocyte super-

ED-T, Embryo development in response to trophoblast antigen–activated leukocyte supernatants; *ED-S*, embryo development in response to sperm antigen–activated leukocyte supernatants; *TP-T*, trophoblast proliferation in response to trophoblast antigen–activated leukocyte supernatants; *TP-S*, trophoblast proliferation in response to sperm antigen–activated leukocyte supernatants.

natants; for trophoblast proliferation, 32% using trophoblast antigen–activated and only 13% using sperm antigen–activated leukocyte supernatants. Only one (3%) of the fertile controls would have been falsely classified as having recurrent abortion with sperm antigen–activated leukocyte supernatant in the embryo development assay, and none would have been falsely classified with the other assay-supernatant combinations.

The embryo development assay was more sensitive than the trophoblast proliferation assay in predicting the propensity for abortion. Only four of 300 women had >50% embryo development when trophoblast proliferation was ≤50% (Table III). If only trophoblast proliferation had been used to assess toxic factor production, 127 women would have been falsely screened as negative. Only 113 women produced toxic factors in response to reproductive antigens in the trophoblast proliferation assay compared with 236 women who tested positive with the embryo development bioassay (Table III).

In Table IV we considered a positive test for recurrent spontaneous abortion to be ≤50% of embryo development in response to either trophoblast or sperm antigen–activated leukocyte supernatants. This allowed us to detect 79% of women with recurrent abortion while still maintaining an extremely low number of false-positive results (3%). This propensity to generate embryo-toxic factors in response to either trophoblast or sperm antigen stimulation was more pronounced in women with an unknown cause as compared with a known cause for their abortion. The presence of embryo- and trophoblast-toxic factors was not influenced by a change in partners because six women in whom toxic factors were produced in response to sperm-antigen stimulation (n = 4) and trophoblast antigen stimulation (n = 2) experienced recurrent abortions with both their prior and current husbands.

The effects of embryo-toxic supernatants on embryo development after molecular weight dialysis indicated that the factor(s) responsible for embryo toxicity in all 15 supernatants tested was between 10 and 30 kd. The embryo-toxic effect of the supernatants was abrogated by heat treatment to 56° C for 1 hour. In 12 of 15 embryo-toxic supernatants the factor(s) was absorbed on affinity columns containing anti–interferon gamma beads. Passage of control media through the anti–interferon gamma column had no effect on embryo development.

Comment

Viable pregnancy is the result of a highly selective process because 10% to 20% of all conceptions end in detectable spontaneous abortion.[3] Recurrent spontaneous abortion is an important clinical problem affecting the reproductive health of up to 1% of women who are gravida ≥3.[17]

Women with recurrent abortion have been categorized as having either primary or secondary abortions depending on whether they have never achieved a viable pregnancy or their first pregnancy resulted in a live birth followed by recurrent abortion.[18] In this study 11% (n = 35) of the women experiencing recurrent abortion defied conventional classification. The use of the terms primary and secondary abortion is therefore limited because of their failure to include women who have had spontaneous abortions interspersed with either live births or ectopic gestations.

This report of 300 couples with recurrent abortion is the largest completed series to date. Earlier reports

of 100,[4] 155,[19] and 195[5] couples with recurrent abortion described parental chromosomal errors in 12%, 15%, and 3% of their study patients, respectively. Our finding of a chromosomal abnormality in 5% of couples with recurrent abortion is in agreement with the 3% prevalence rate observed in the next largest reported series of 195 couples.[5] The discrepancy in the percentage of individuals with various causes between studies may be due to differences in sample size, differences in diagnostic criteria, and inherent bias afforded by physician referral patterns of patients with recurrent abortion.

Nongenetic causes of recurrent abortion are difficult to ascribe, although numerous associations have been made with anatomic, endocrine, infectious, and humoral immune abnormalities.[3] Anatomic anomalies occurred in 10% of the women in our study with recurrent abortion, which is similar to the 15% rate reported in two of the other series of 100 and 195 patients.[4,5] A diagnosis of septate uterus accounted for the majority of women in our study with an anatomic cause. Timing of fetal loss in these women was equally distributed between the first and second trimesters. Uterine anomalies have been primarily associated with second-trimester fetal loss.[20] However, first-trimester losses may occur as a result of vascular insufficiency and inadequate endometrial development resulting in abnormal placentation. Endocrinologic dysfunction occurred in 17% of our patients, which is also similar to findings in other published series.[4,5] The majority (88%) of our patients with an endocrinologic abnormality had luteal phase insufficiency. The significance of luteal phase deficiency in recurrent abortion, like other nongenetic associations, is controversial.[3] However, every attempt was made in this study to eliminate possible contributing factors to recurrent abortion. Thus a series of women was identified with an otherwise unexplained cause of reproductive failure to test the hypothesis that reproductive antigens stimulate lymphocytes and macrophages from some women with recurrent abortion to secrete soluble factors that are capable of inhibiting embryo development and trophoblast proliferation as a possible mechanism for spontaneous abortion.

Both sperm and trophoblast antigens in this study stimulated peripheral blood lymphocytes and macrophages from many of the women with recurrent abortion to secrete factors that adversely affected embryo development and trophoblast proliferation in vitro. The trophoblast antigen used in this study was derived from the choriocarcinoma cells lines BeWo and Jeg-3. These cell lines were chosen as the trophoblast antigen model for three reasons: (1) They are homogeneous trophoblast cell lines uncontaminated by other cellular constituents such as stromal mesenchymal cells or lymphoid and myeloid populations that are always associated with normal placental trophoblast[21]; (2) like normal trophoblast, they are devoid of classic major histocompatibility complex class I and II antigens[22]; (3) they are established antigenic models of early normal trophoblast because of their invasive capabilities and cell surface antigen profiles that are similar to those of early normal human trophoblast.[23,24] Placental trophoblast isolation techniques have to date been unable to achieve absolute purity, and even low levels (<2%) of allogeneic immune cell contamination are sufficient to cause a mixed lymphocyte reaction if these trophoblast preparations are cocultured with leukocytes from a different individual or with other cell lines expressing either major histocompatibility complex class I or II antigens (unpublished observations). This is important to avoid because supernatants generated from mixed lymphocyte cultures even from fertile individuals contain factors capable of inhibiting embryo development in vitro.[8] This is not surprising because abundant concen-

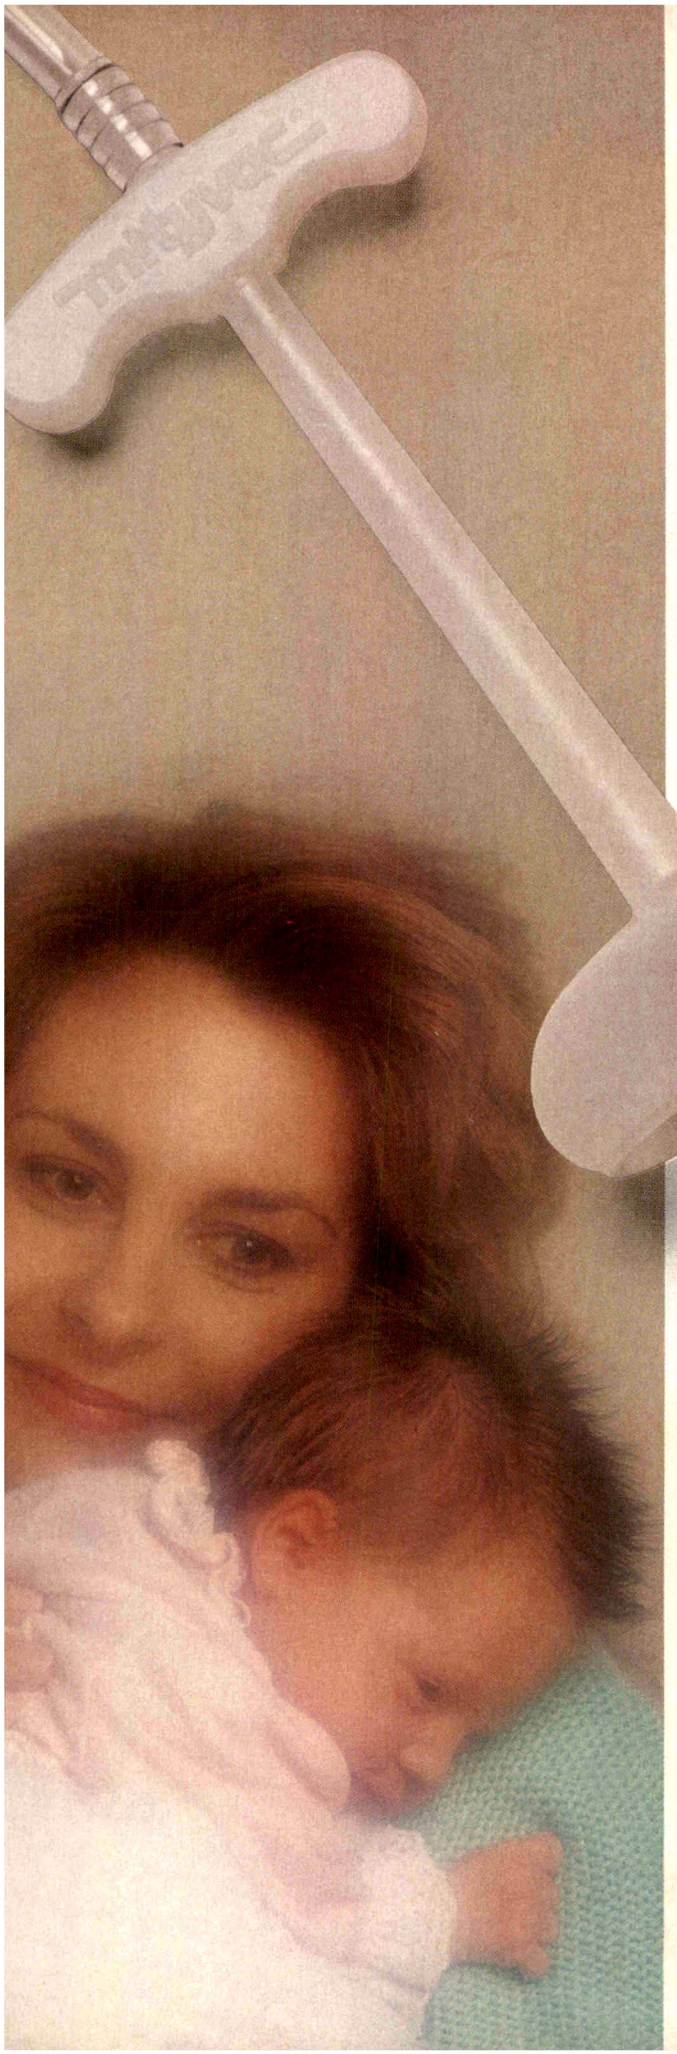
trations of cytokines including interferon gamma and tumor necrosis factor-α can be isolated from mixed lymphocyte culture supernatants.[25] There were no observed differences between BeWo and Jeg-3 antigen preparations in terms of their ability to stimulate embryo-toxic factor release from activated leukocytes of susceptible individuals. Therefore these two trophoblast antigen sources were used interchangeably.

Antibody responses directed against sperm antigens are well described as factors contributing to female infertility.[26] In addition to affecting prefertilization events, antisperm immunity may also mediate early embryonic loss.[27] Cellular immunity to sperm has also been suggested to participate in infertility mechanisms[28] and has been speculated to contribute to abortion.[29] Many studies have revealed the presence of sperm antigens on the fertilized egg, early embryo, and developing trophoblast.[30] Therefore it may not be surprising to find, within a group of women with recurrent abortion, those who produce either embryo-toxic or trophoblast-toxic factors in response to sperm antigen stimulation.

Women with unexplained cause of recurrent abortion had a high incidence of embryo-toxic and trophoblast-toxic factor production in response to reproductive antigen stimulation. Of 180 women with an unexplained cause for their recurrent abortions, approximately 90% had production of embryotoxic (<50% embryo development, $n = 161$) and/or trophoblast-toxic (<50% trophoblast proliferation, $n = 75$) factors in response to either trophoblast antigen or sperm antigen activation (Table III). Approximately 78% of the women with a presumed endocrinologic abnormality as the cause for their recurrent abortions also had production of these toxic factors. The majority of these women (88%) had a diagnosis of luteal phase deficiency. It is possible that the generation of embryotoxic factors is associated with luteal phase deficiency and contributes to or is responsible for abortion in these women. Luteal phase deficiency may even be a marker for embryo-toxic factor production because many women with luteal phase deficiency have increased concentrations of T lymphocytes in the endometrium that are capable of cytokine secretion, as compared with concentrations in endometrial biopsy specimens from women without luteal phase deficiency.[31] Similarly, many of the women in this study who were found to have a humoral immune (antibody) abnormality as a potential cause for recurrent abortion also had production of embryo-toxic factors in response to reproductive antigen stimulation. Women with antisperm antibodies in this study did not have embryo-toxic factors produced in response to sperm antigen stimulation but instead in response to trophoblast antigens (data not shown). This may be attributable to either lack of association between humoral and cellular immunity to sperm antigens or cross reactivity of sperm antigens with dominant antigens in the trophoblast extract preparation. However, the number of women with antisperm antibodies in this study was too small for definitive conclusions. Women with either an anatomic or a genetic cause of recurrent abortion were less likely to have toxic factors produced in response to reproductive antigen stimulation than women with other causes of abortions. The finding of embryo-toxic and trophoblast-toxic factors in some women with endometriosis is interesting. However, it may not be uncommon for individuals to have more than one cause contributing to reproductive failure. Cause-and-effect relationships are difficult to ascribe; it is possible that in some women embryo-toxic factor production was related to exposure to degenerating or necrotic fetal-placental tissue that occurred during a previous pregnancy failure. However the cytotoxic cellular immune mechanism is initiated, embryo-toxic factor production could be the cause of subsequent abortion.

Our study indicates that the preimplantation embryo is a vulnerable target of cytotoxic factors produced by activated leukocytes from many women with recurrent abortion, yet the clinical histories of these patients indicate that their pregnancies aborted after the implantation stage. We do not know at the present time to what extent immunologic embryo-toxic factors contribute to idiopathic infertility, but this possibility is currently under investigation. In patients with recurrent abortion detrimental effects of immune activation could be manifested later in gestation because of a delayed response and/or inadequate antigenic stimulus provided by the preimplantation embryo.

Female reproductive tissues contain abundant immune cells capable of responding to antigen stimulation.[7, 32] Products of activated immune cells, collectively termed cytokines, affect many reproductive processes in vitro. The T-lymphocyte cytokine interferon gamma inhibits both embryo development[8] and trophoblast proliferation[9] over a wide concentration in vitro. Interestingly, one form of interferon gamma has a molecular weight of 17,000 kd, which is comparable to that of the embryo-toxic factor isolated in our molecular weight dialysis experiments. Furthermore, interferon gamma is heat labile.[33] Our finding that embryo toxicity was abrogated in 12 of 15 supernatants after passage through an affinity column containing antibody against interferon gamma suggests that the factor responsible for embryo toxicity in these supernatants may be interferon gamma or a soluble immune cell factor that either has strong affinity for this cytokine or works in synergy with interferon gamma. A number of products of activated macrophages have also been reported to have toxic effects on preimplantation embryos and trophoblast cell lines.[8, 9] These or other, as



yet unidentified soluble immune cell factors may have contributed to embryo toxicity, especially in the 3 of 15 supernatants that retained toxic activity in spite of passage through the interferon gamma affinity columns.

The precise nature and extent of immunologic mechanisms for recurrent abortion are not well understood. The data presented in this study suggest that a potential mechanism of immunologic recurrent abortion may involve the secretion of inteferon gamma or other cytokines produced by activated lymphocytes and macrophages within female reproductive tissues in response to either trophoblast or sperm antigens.

We thank Dr. Isaac Schiff for his advice and support and Dr. Florina Haimovici for her technical assistance.

NEW FROM MITYVAC®

"M" STYLE MECHANICAL PULL VACUUM EXTRACTOR

Mityvac®'s new "M" Style Vacuum Extractor Cup is uniquely shaped to provide greater traction and excellent manipulation during vacuum assisted deliveries. The extractor cup is softly contoured and the flexible stem bends into a 90-degree angle, providing the "M" Style Cup with several distinct advantages:

- **Newly styled cup is shaped to provide mechanical pull for greater traction**
- **Even at 90-degree angle, extractor cup holds tight vacuum and continues to perform throughout delivery**
- **Manipulable design provides optimum angle of application when minimal space is available**
- **Smooth, low profile cup and flexible stem provide safe, easy insertion**
- **Lightweight, flexible material enhances manipulation capabilities**
- **Technologically advanced one-piece ventouse is fully assembled and ready for immediate use**
- **Individually prepackaged in sterile pouches, the extractor cup, tube and filter are disposable**
- **Fully compatible with all Mityvac® pumps**

The "M" Style Cup provides firm control throughout delivery.

The patented manipulable design draws vacuum and remains fully functional even at a 90-degree angle.

As pioneers of vacuum delivery technology in childbirth for more than 20 years, Mityvac® products of quality and reliability fulfill obstetrical needs around the world.

mityvac®
OBSTETRICAL
VACUUM DELIVERY SYSTEM

A Division of Neward Enterprises, Inc.
9251 Archibald Avenue, Rancho Cucamonga, CA 91730
(800) 648-9822

These days, this isn't all you have to deliver.

Every year, there are more treatments, technologies, therapies and drugs. New diseases are discovered.

And the delivery of medical care is changing constantly.

Which is why Caremark, an affiliate of Baxter Healthcare Corporation and the national leader in alternate site care, created Women's Health.

Caremark Women's Health has comprehensive services to help you support patients throughout their lives, from the management of high risk pregnancies, to treatment for infectious diseases, to oncology, to midlife gynecology.

With our sophisticated yet simple First Activity™ Monitor, you can now oversee high risk pregnancies 24 hours a day, seven days a week. Use of the device to detect pre-term labor (prior to 36 week gestation), is still considered investigational.

First Activity™ Monitor lets patients collect and store data on uterine activity and other physiological indicators at home.

Then, they transmit it by phone to a perinatal nurse in one of our nationwide Women's Health Centers, who notifies you immediately if there's a problem.

So you receive accurate and timely information, allowing you to prescribe the best treatment, at the right time.

And with skilled Caremark pharmacists, perinatal and IV nurses available day and night, your patients will get the specialized care you prescribe.

If you'd like to know more about how we can support you, call Caremark Women's Health at 1-800-423-1411.

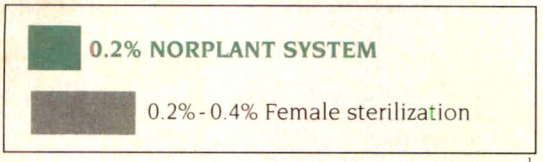
We can help you deliver more.

Caremark Women's Health.

CAREMARK
Affiliate Baxter Healthcare Corporation

NORPLANT® SYSTEM

levonorgestrel implants



Six reasons why you can feel comfortable recommending it to your patients

Effectiveness comparable to tubal ligation

Although no contraceptive is 100% effective, the NORPLANT SYSTEM is one of the most effective forms of birth control ever developed. The average annual gross pregnancy rate over a five-year period is less than 1%.

Lowest expected and typical failure rates with NORPLANT SYSTEM vs. sterilization during first-year use[1]

Adapted from Trussell J, et al.[1]

Long-term convenience... estrogen-free

NORPLANT SYSTEM, a progestin-only contraceptive, is an excellent option for women desiring a long-term method. Its effectiveness lasts for five years and is not dependent on compliance.

Reversible, with prompt return to previous level of fertility

NORPLANT SYSTEM is reversible at any time; the contraceptive effect ceases when the capsules are removed. In one study, 40% of women wanting to conceive did so within 3 months of removal, 63% by 6 months, 76% by 12 months, and 90% by 24 months.[2]

High patient acceptance despite menstrual pattern changes

NORPLANT SYSTEM causes menstrual irregularities (the most common complaint),* which occur in many women during first-year use and diminish over time. Only 9.1% of patients discontinued during first-year use due to these changes.[3†]

Women who are thoroughly informed of potential menstrual changes and side effects are more tolerant of them when they occur.[4]

Well-received, well-liked by American women

One study of 140 users revealed that 94% were satisfied with NORPLANT SYSTEM, 91% recommended it to their friends, and 74% wanted to use it again.[5]

A 10- to 15-minute office procedure

A local anesthetic and a small 2 mm incision...little or no discomfort during insertion...proper placement should not leave a noticeable scar...in most cases sutures are not needed.

*Serious as well as minor side effects may occur (see prescribing information).

†Based on multicenter trials of 2,470 women.

Please see brief summary of prescribing information on adjacent page.

NORPLANT® SYSTEM
levonorgestrel implants

Lasts 5 years...yet is reversible

NORPLANT® SYSTEM

levonorgestrel implants

Lasts five years…yet is reversible

BRIEF SUMMARY OF PRESCRIBING INFORMATION. CONSULT THE PACKAGE LITERATURE FOR FULL PRESCRIBING INFORMATION.

Indications and Usage

The NORPLANT SYSTEM is indicated for the prevention of pregnancy and is a long-term (up to 5 years) reversible contraceptive system. The capsules should be removed by the end of the 5th year. New capsules may be inserted at that time if continuing contraceptive protection is desired.

Contraindications

1. Active thrombophlebitis or thromboembolic disorders. 2. Undiagnosed abnormal genital bleeding. 3. Known or suspected pregnancy. 4. Acute liver disease; benign or malignant liver tumors. 5. Known or suspected carcinoma of the breast.

Warnings

A. WARNINGS BASED ON EXPERIENCE WITH THE NORPLANT SYSTEM

1. *Bleeding Irregularities* — Most women can expect some variation in menstrual bleeding patterns. Irregular menstrual bleeding, intermenstrual spotting, prolonged episodes of bleeding and spotting, and amenorrhea may occur, and could mask symptoms of cervical or endometrial cancer. Overall, these irregularities diminish with continued use. Because amenorrhea may occur, missed menstrual periods cannot serve as the only identifier of early pregnancy. Perform pregnancy tests whenever pregnancy is suspected. If pregnancy occurs, the capsules must be removed.
Hemoglobin concentrations found in clinical trials generally indicated that reduced menstrual blood loss is associated with NORPLANT SYSTEM use. Blood loss resulting in hemoglobin values consistent with anemia occurred rarely.

2. *Delayed Follicular Atresia* — Atresia of the follicle is sometimes delayed, resulting in enlarged follicles that are clinically indistinguishable from ovarian cysts. In the majority of women, enlarged follicles disappear spontaneously. Rarely, they twist or rupture and surgical intervention may be required.

3. *Ectopic Pregnancies* — Ectopic pregnancies have occurred among NORPLANT SYSTEM users, although clinical studies have shown no increase in the rate of ectopic pregnancies per year among NORPLANT SYSTEM users as compared with users of no method or of IUDs. The incidence among NORPLANT SYSTEM users (1.3 per 1000 woman-years) was significantly below the rate estimated for noncontraceptive users in the U.S. (2.7 to 3.0 per 1000 woman-years). Ectopic pregnancy risk may increase with duration of NORPLANT SYSTEM use and increased weight of the user. Rule out ectopic pregnancy in any patient presenting with lower-abdominal pain.

4. *Breast-feeding* — Steroids are not the contraceptives of first choice for lactating women. Levonorgestrel has been identified in breast milk. Limited data suggests no significant effects on infant growth or health when mothers used the NORPLANT SYSTEM beginning 6 weeks after parturition.

5. *Foreign-body Carcinogenesis* — Rarely, cancers occur at foreign-body intrusion sites or old scars. None has been reported in NORPLANT SYSTEM clinical trials and risk to users is judged to be minimal.

6. *Thromboembolic Disorders* — Remove capsules if active thrombophlebitis or thromboembolic disease develops. With prolonged immobilization removal should be considered.

B. WARNINGS BASED ON EXPERIENCE WITH COMBINATION (PROGESTIN PLUS ESTROGEN) ORAL CONTRACEPTIVES (OCs)

Note: Many of the side effects or risks listed below are thought to be estrogen-related; the association of the NORPLANT SYSTEM progestin-only method to these risks is unknown.

1. *Cigarette Smoking* — Cigarette smoking increases the risk of serious cardiovascular side effects from combined OC use. Risk increases with age and heavy smoking (≥15 cigarettes/day) and is quite marked in women over 35 years old.

2. *Elevated Blood Pressure* — Increase in blood pressure has been reported in combination OC users; prevalence increases with long exposure.

3. *Thromboembolic Disorders and Other Vascular Problems* — An increased risk of thromboembolic and thrombotic disease is associated with combination OC use. Estimate of relative risk is 4- to 11-fold higher for users vs. nonusers.
Cerebrovascular Disorders: Combination OCs increase the relative and attributable risk of cerebrovascular events (thrombotic and hemorrhagic strokes). Generally, risk is greatest among hypertensive women > 35 years of age who smoke.
Myocardial Infarction (MI): An increased risk of MI has been attributed to combined OC use. This is thought to be primarily thrombotic in origin and related to the estrogen component. Increased risk occurs primarily in smokers or women with other underlying risk factors for coronary-artery disease. Relative risk of heart attack for combined OC users is estimated as 2 to 6 times that for nonusers. Absolute risk is very low for women under 30 years old.
Studies indicate a significant trend toward higher MI and stroke rates with increased progestin doses in combination OCs. However, recent data indicated no increased MI risk with past use of levonorgestrel-containing OCs.

4. *Carcinoma* — Recent evidence in the literature suggests no association between OC use and increased risk of breast cancer in the overall population of users. The Cancer and Steroid Hormone (CASH) study also showed no latent effect on breast cancer risk for at least a decade following long-term use. Some of these same studies have shown an increased relative risk of breast cancer in certain subgroups; no consistent pattern has been identified. Some studies suggest an association between combination OCs and an increase in the risk of cervical intra-epithelial neoplasia in some populations of women. The extent to which such findings may be due to differences in sexual behavior and other factors remains controversial. A cause-and-effect relationship between combined OC use and breast or cervical cancer has not been established. Combination OCs may decrease ovarian and endometrial cancer risk. Irregular bleeding patterns associated with NORPLANT SYSTEM use could mask cervical or endometrial cancer symptoms.

5. *Hepatic Tumors* — Hepatic adenomas are associated with combination OC use; estimated incidence is 3 events per 100,000 users per year. Risk increases after 4 or more years of use. Hepatic adenomas are benign but may rupture and cause death through intra-abdominal hemorrhage.

6. *Ocular Lesions* — Retinal thrombosis is associated with OC use and is believed to be related to the estrogen component. However, NORPLANT SYSTEM capsules should be removed if there is unexplained partial or complete vision loss; onset of proptosis or diplopia; papilledema; or retinal vascular lesions. Undertake appropriate diagnostic and therapeutic measures immediately.

7. *Use Before or During Early Pregnancy* — Extensive epidemiological studies reveal no increased risk of birth defects when OCs are used prior to pregnancy. Studies also do not suggest a teratogenic effect when taken inadvertently during early pregnancy. No evidence suggests that risk with NORPLANT SYSTEM use is different.

8. *Gallbladder Disease* — Early studies reported an increased lifetime relative risk of gallbladder surgery in OC or estrogen users. More recent studies, however, indicate that the relative risk of gallbladder disease with OC use may be minimal; this may be related to use of OCs with less estrogen and progestin content.

Precautions

GENERAL

1. *Physical Examination and Follow-up* — A complete medical history and physical examination should be taken prior to implantation or reimplantation of NORPLANT SYSTEM capsules and at least annually during its use. Exams should include special reference to the implant site, blood pressure, breasts, abdomen and pelvic organs, including cervical cytology and relevant laboratory tests. Rule out malignancy in cases of undiagnosed, persistent or recurrent abnormal vaginal bleeding. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care.

2. *Carbohydrate Metabolism* — Altered glucose tolerance is found in some combination and progestin-only OC users. Effects of NORPLANT SYSTEM on carbohydrate metabolism appear minimal. Observe diabetic and prediabetic patients carefully while using the NORPLANT SYSTEM. Follow women being treated for hyperlipidemias closely if using the NORPLANT SYSTEM. Some progestins may elevate LDL and may render control of hyperlipidemias more difficult. (See **Warnings**.)

3. *Liver Function* — Consider removing capsules if jaundice develops. Steroid hormones may be poorly metabolized in patients with impaired liver function.

4. *Fluid Retention* — Steroid contraceptives may cause some degree of fluid retention. Prescribe with caution, and careful monitoring, in patients with conditions possibly aggravated by fluid retention.

5. *Emotional Disorders* — Consider removing capsules if significant depression occurs since the symptom may be drug-related. Observe carefully those with history of depression and consider removal if depression recurs to a serious degree.

6. *Contact Lenses* — Contact-lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist.

7. *Insertion and Removal* — Insertion is advised during the first 7 days of the cycle or immediately following abortion to insure that the woman is not pregnant and to assure contraceptive effectiveness during first cycle of use. Capsules may be inserted at any time during the cycle provided pregnancy has been excluded and a nonhormonal contraceptive method is used for the remainder of the cycle. Insertion is not recommended before 6 weeks postpartum in breast-feeding women. Follow insertion and removal instructions closely. Healthcare professionals are strongly advised to be instructed in the procedures before they attempt them. Proper insertion just under the skin facilitates removals; proper insertion and removal should result in minimal scarring. If all capsules cannot be removed at first attempt, attempt removal later when the site has healed. Bruising may occur at implant site during insertion or removal. Hyperpigmentation may occur over implant site but is usually reversible following removal. **See Full Prescribing Information for Detailed Insertion/Removal Instructions.**

8. *Infections* — Implant site infection has been uncommon (0.7%); aseptic technique and proper insertion/removal reduces possibility of infection. Institute treatment if infection occurs; remove capsules if infection persists.

9. *Expulsion* — Expulsion of capsules was uncommon; frequency increased when capsule placement was extremely shallow, was too close to incision, or when infection was present. Replace expelled capsule with new sterile capsule. Treat and cure any infection before replacement. Contraceptive efficacy may be inadequate with fewer than 6 capsules.

10. *Provisions for Removal* — Advise women that capsules may be removed at any time for any reason. Personnel instructed in removal technique should perform removal on request or at the end of 5 years of usage. Upon removal, dispose of capsules in accordance with Centers for Disease Control Guidelines for biohazardous waste.

DRUG INTERACTIONS: Reduced efficacy (pregnancy) in NORPLANT SYSTEM users has been reported when phenytoin or carbamazepine were used concomitantly. Warn NORPLANT SYSTEM users of possible decreased efficacy with use of related drugs.

DRUG/LABORATORY TEST INTERACTIONS: 1. Sex-hormone-binding globulin concentrations are decreased. 2. Thyroxine concentrations may be slightly decreased and triiodothyronine uptake increased.

CARCINOGENESIS: See **Warnings** section and Full Prescribing Information.

PREGNANCY: Pregnancy Category X. See **Warnings** section and Full Prescribing Information.

NURSING MOTHERS: See **Warnings** section and Full Prescribing Information.

INFORMATION FOR THE PATIENT: See Patient Labeling. Provide copy of patient labeling to the patient. Advise patients that Prescribing Information is available upon request. Inform prospective users of risks and benefits associated with NORPLANT SYSTEM use, with other forms of contraception, with no contraception, and about insertion/removal procedures. Informed consent from all patients may be desired in light of techniques involved with insertion and removal.

Adverse Reactions

The following have been associated with the NORPLANT SYSTEM during first year of use: many bleeding days or prolonged bleeding (27.6%); spotting (17.1%); amenorrhea (9.4%); irregular (onsets of) bleeding (7.6%); frequent bleeding onsets (7.0%); scanty bleeding (5.2%); pain or itching near implant site - usually transient - (3.7%); infection at implant site (0.7%); removal difficulties affecting subjects - based on 849 removals - (6.2%).
Controlled clinical studies suggest that the following, occurring during the first year, are probably associated with NORPLANT SYSTEM use: headache; nervousness; nausea; dizziness; adnexal enlargement; dermatitis; acne; change of appetite; mastalgia; weight gain; hirsutism, hypertrichosis, and scalp-hair loss. The following were reported with a frequency of 5% or greater during the first year and possibly may be related to NORPLANT SYSTEM use: breast discharge; cervicitis; musculoskeletal pain; abdominal discomfort; leukorrhea; vaginitis.

Overdosage

Overdosage may cause fluid retention with its associated effects and uterine bleeding irregularities.

Dosage and Administration

The NORPLANT SYSTEM consists of six Silastic® capsules, each containing 36 mg of the progestin, levonorgestrel. The total administered (implanted) dose is 216 mg. Implantation of all six capsules should be performed during the first 7 days of the onset of menses by a healthcare professional instructed in the NORPLANT SYSTEM insertion technique. Insertion is subdermal in the midportion of the upper arm about 8 to 10 cm above the elbow crease. Distribution should be in a fanlike pattern, about 15 degrees apart, for a total of 75 degrees. Proper insertion will facilitate later removal. **(See Full Prescribing Information for Detailed Insertion/Removal Instructions.)**

Functional analysis of a mutant estrogen receptor isolated from T47Dco breast cancer cells

Kimberly K. Leslie, MD,[a] Diane M. Tasset, PhD,[b] and Kathryn B. Horwitz, PhD[b]

Denver, Colorado

OBJECTIVE: Estrogen receptor–positive cancers that initially respond to hormone therapy often progress to a resistant state. The breast cancer cell line T47Dco is a model for such resistance. It is a polymorphic line, composed of multiple cell populations that demonstrate the presence of mutant estrogen receptors by cloning and sequencing techniques. Our objective was to isolate and analyze the structural and functional characteristics of the T47Dco mutant estrogen receptor complementary deoxyribonucleic acid clones.

STUDY DESIGN: We constructed two independent T47Dco complementary deoxyribonucleic acid libraries. We isolated and sequenced T47Dco estrogen receptors and have identified a mutant receptor that is truncated near the end of the deoxyribonucleic acid binding domain. This mutant has now been recreated with site-directed mutagenesis and tested for its ability to bind to deoxyribonucleic acid, dimerize with other estrogen receptors, and activate gene transcription by the chloramphenicol acetyltransferase assay and by gel shift assays.

RESULTS: The chloramphenicol acetyltransferase assays reveal that in the absence of estradiol low levels of conversion of chloramphenicol to acetylated products occur when the mutant estrogen receptor is used to activate chloramphenicol acetyltransferase gene transcription, supporting that it has some constitutive function. Also, gel mobility shift assays demonstrate low levels of deoxyribonucleic acid binding with the mutant protein.

CONCLUSION: This mutant estrogen receptor may contribute to the estrogen receptor–positive, hormone-resistant phenotype of T47Dco cells by constitutively binding to and activating genes that were previously estradiol dependent. (Am J Obstet Gynecol 1992;166:1053-61.)

Key words: Breast cancer, hormone resistant, mutant estrogen receptors, deoxyribonucleic acid binding domain mutation, constitutive gene regulation

Estradiol stimulates normal mammary and endometrial epithelial growth and development in an action mediated by estrogen receptors. Estradiol also stimulates the growth of cancers that arise from these tissues in the early stages of the metaplastic process. The hormone binds to estrogen receptor, and the steroid-receptor complex interacts with chromatin to regulate specific gene transcription, bringing about estrogen-stimulated growth. This model is supported by studies that show a clear association between estrogen receptor levels and growth in human mammary and endometrial tumors,[1] by studies that show estrogen stimulation of cell growth in MCF-7 and ZR-75 human breast cancer cells[2, 3] and Ishikawa human endometrial cells,[4] and by studies in which estrogen-stimulated growth is suppressed by antiestrogens and rescued by estradiol.[5]

Tumors that require estrogen for growth are termed hormone dependent, and these tumors usually respond to endocrine therapy in the initial phases of treatment. However, as some tumors become anaplastic, their normal responses to estrogens are subverted; these tumors no longer require estradiol for growth and are classified as hormone resistant. Many resistant tumors no longer express estrogen receptors, and this may be the basis for their resistant state. However, 30% of all breast cancers are estrogen receptor positive, yet they do not respond to antiestrogen hormonal therapy.[6] The focus of our research has been to explain the estrogen receptor–positive, hormone-resistant phenotype. We hypothesize that genetic instability within some cancers leads to the generation of heterogeneous cell populations, some of which may express mutant estrogen receptors that function abnormally.

This model for hormone resistance is based on studies of the breast cancer cell line T47Dco. Previous studies from our laboratory have identified several unusual characteristics of this line.[7] By sucrose density gradient

analysis, T47Dco cells contain essentially no unfilled cytoplasmic (<3 fmol/mg protein) or nuclear estrogen receptors in the 8S region. Scatchard analysis of protamine sulfate–precipitated estrogen receptors shows that there are low levels of an unusual class of nuclear estrogen receptors present. They are unusual in that (1) they are tightly bound to chromatin without estrogen treatment and (2) the nuclear estrogen receptors can be measured only at elevated temperatures, suggesting a structural alteration in the protein.

In addition to the possibility that structural anomalies are present, the T47Dco estrogen receptors are functionally anomalous when compared with classically estrogen receptor–positive breast cancer cells such as MCF-7. Estradiol treatment fails to down-regulate the estrogen receptors of T47Dco cells, and antiestrogens do not suppress cell growth. Interestingly, however, T47Dco cells do express estrogen receptor messenger ribonucleic acid (mRNA). These cells also express very high levels of progesterone receptors, but the progesterone receptors of T47Dco cells cannot be regulated in the normal manner; that is, estradiol does not raise progesterone receptor levels and antiestrogens do not suppress them.

Like solid tumors, the T47Dco line exhibits genetic instability over time in cell culture. We have previously shown that the parental T47Dco line is composed of multiple cell populations, which, when cloned by limiting dilution, exhibit phenotypes varying from classically estradiol responsive to completely estradiol resistant.[8] On the basis of these observations, we postulate that T47Dco models stage IV breast cancer and that some of its subclones may express variant estrogen receptors.

To investigate this hypothesis, we previously constructed two independent complementary deoxyribonucleic acid (cDNA) libraries from the parental T47Dco line and cloned and sequenced several estrogen receptor cDNAs.[8] In addition to clones composed of normal estrogen receptor sequences, we identified several mRNAs that encode putative proteins with interesting mutations. We have expanded our investigations into the functional significance of one of these mutant receptors, the deoxyribonucleic acid (DNA) binding domain or DBD mutant, by using site-directed mutagenesis to generate an expression vector that has allowed us to express the protein in Cos-1 and HeLa cells. The ability of the mutant protein to bind to DNA, to form dimers with wild-type estrogen receptors, and to activate gene transcription is explored.

Material and methods

cDNA isolation and sequencing of mutant estrogen receptor cDNA. Two cDNA libraries were made. For library 1 polyadenylated mRNA, isolated from estrogen receptor–positive, estrogen-resistant T47Dco cells, was used to direct cDNA synthesis with two human estrogen receptor–specific oligonucleotides as primers. One 24-mer, 5′-CCC CAC TTC ACC CCT GCC CTC CCC-3′, was complementary to base pairs 1052 to 1075 of the estrogen receptor message in the hinge region D; the second, a 30-mer, 5′-GGG GGA AAG AGA GCT GTT ACA AAG ATT TAG-3′, was complementary to base pairs 2230 to 2259 in the 3′ untranslated region.[9-11] The cDNA was synthesized and cloned ino bacteriophage SWAJ-4 by Clontech (Palo Alto, Calif.).

In library 2 cytoplasmic polyadenylated mRNA was the starting material. Double-stranded cDNA was synthesized with the two estrogen receptor oligonucleotides used as primers. *Eco*RI/*Not*I linker-adapters were ligated to blunt-ended cDNA. The products were phosphorylated, and fragments larger than 300 bp were gel purified, electroeluted, and ligated to λ-gt10 cut with *Eco*RI and then dephosphorylated. Ligated recombinants were packaged into phage with *in vitro* packaging extracts (Invitrogen, San Diego) and were amplified in *Escherichia coli* C600hfl. The two cDNA libraries consisted of 4×10^5 and 3×10^6 independent recombinants before the amplification step.

Approximately 5×10^5 phage from each library were screened for estrogen receptor sequences by plaque hybridization with a 2.1 kb human estrogen receptor nick-translated cDNA probe encompassing the protein-coding region, which was kindly supplied by A. Baker.[11] Seven independently isolated types of recombinant phage from library 1 and five from library 2 were randomly picked and purified to homogeneity by three rounds of screening. Bacteriophage was prepared from plate lysates, and phage DNA was purified with Lambda Sorb (Promega, Madison, Wis.) according to the manufacturer's instructions.

For library 1 pGEM-1 containing the cDNA was prepared by recircularization after release from SWAJ-4 by restriction digestion with *Spe*I. For library 2 the cDNA insert was isolated with *Eco*RI and recloned into pGEM7Zf(+) (Promega). Double-stranded plasmid DNA containing the cDNA inserts was alkali denatured and both strands were sequenced (Sequenase, United States Biochemical Corp., Cleveland) with use of SP6 and T7 promotor primers and overlapping synthetic estrogen receptor oligonucleotide primers. Sequences were compared against those reported in the Genetic Sequence Data Bank (GenBank, Beckman, release 59, Palo Alto, Calif.).

Constructions of the DBD estrogen receptor mutant. Site-directed mutagenesis[10] was used to construct a pSG5 vector[12] containing the coding region for the DBD estrogen receptor mutant. Double-stranded wild-type human estrogen receptor in the expression vector pSG5 (HEGO-pSG5) was kindly provided by P. Cham-

bon and was transfected into TG2 *E. coli* with helper phage M13K07 (Promega). When growth with this phage occurred, single-stranded wild-type estrogen receptor template DNA was obtained. An oligonucleotide spanning the estrogen receptor sequence that was mutated in the DBD mutant was constructed on a Cyclone Plus DNA synthesizer (Milligen/Biosearch, Burlington, Mass.). Two thymidine residues were added to the sequence of the oligonucleotide to create the identical frame shift mutation that was present in the naturally occurring DBD estrogen receptor mutant from T47Dco, thus creating the TGA stop codon. Downstream from this site, an *Eco*RI restriction site was also added to the oligonucleotide sequence. This site was used to screen recombinants for the mutant sequence. The phosphorylated mutant oligonucleoide was annealed to the single-stranded wild-type template, and the second strand was elongated. The resultant double-stranded hybrid mutant-wild-type vector was used transform DH5 *E. coli* cells that were screened with *Eco*RI restriction digestion. Colonies expressing the mutant vector were isolated and purified by retransformation and repeat screening. The presence of the correct mutant seqence was verified by Sanger dideoxy sequencing.

The chloramphenicol acetyltransferase assay. The vit-tk-CAT reporter vector was constructed by placing the *Xenopus vitellogenin* A2 (vit) upstream sequence (−331 to −87) and the herpes simplex virus thymidine kinase (tk) promoter (−105 to +51) upstream from the bacterial gene for chloramphenicol acetyltransferase.[13] Chloramphenicol acetyltransferase enzyme assays were performed as described by Gorman et al.[14] Briefly, subconfluent HeLa and Cos-1 cells in 90 mm culture plates were cotransfected in duplicate by calcium phosphate coprecipitation with different amounts of the receptor expression vectors (DBD or wild-type), 3 μg of the β-galactosidase vector pCH110 (Clontech) and 1 μg of the estradiol-responsive reporter vit-tk-CAT. The total amount of DNA transfected was normalized to 20 μg per plate with the DNA vector Bluescribe M13+. The cells were cultured for 48 hours in the presence of 10^{-8} mol/L estradiol, and the cell extracts were prepared by four cycles of freeze-thawing followed by centrifugation at 10,000*g* for 15 minutes. The efficiency of transcription was determined by assaying each culture plate for β-galactosidase activity with spectrophotometric analysis. The chloramphenicol acetyltransferase analysis was performed with cell extract amounts equal to 50 (for HeLa cells) and 1000 (for Cos-1 cells) units of β-galactosidase activity for 1 hour at 37° C. The acetylated and nonacetylated forms of carbon 14–chloramphenicol were separated by thin-layer chromatography and quantitated from an autoradiograph of the thin-layer chromatography plate by densitometry. Substrate conversion was further quantitated by assessing the radioactivity present on the thin-layer chromatography plate in a scintillation counter.

Gel shift assay. HeLa and Cos-1 cells at 50% confluence in 90 mm culture plates were transiently transfected with 5 μg of plasmid DNA of receptor expression vector (wild-type or DBD mutant estrogen receptor) and 3 μg of pCH110 vector and then normalized for DNA transfection to 20 μg with Bluescribe M13+ by the calcium phosphate coprecipitation technique. The cells were grown for 48 hours in the absence of hormone, and then 10^{-8} mol/L estradiol was added to the culture media 2 hours before harvesting. The cells were washed with chilled phosphate-buffered saline solution, collected, and homogenized in 20 mmol/L Tris-hydrochloride (pH 7.5), 2 mmol/L dithiothreitol, and 20% glycerol containing 0.4 mol/L potassium chloride. After centrifugation at 100,000*g* for 1 hour at 4° C, the whole-cell-extract supernatant was collected and transcriptional efficiency was determined by β-galactosidase activity. The gel shift experiments were carried out after the method of Kumar and Chambon.[15] Briefly, whole-cell extract containing either individual receptor forms or a mixture of two forms (8 to 12 μg protein) was incubated with 2 μg of poly (dI:dC) (Pharmacia, Piscataway, N.J.) at 0° C for 15 minutes. The binding reaction, initiated by adding 35,000 counts/min per lane of phosphorus 32-5′ end-labeled oligonucleotide probe representing the wild-type estrogen response element corresponding to −308 to −342 of the promoter-upstream element of the *X. vitellogenin* A2 gene, was incubated at 20° C for 20 minutes. Some reactions were also incubated in the presence of 100 ng of unlabeled estrogen response element DNA, 100 ng of unlabeled progesterone response element DNA, or estrogen receptor antibody (H-222 or H-226, Abbott, Chicago). The reactions were loaded onto a prerun 4.5% polyacrylamide gel containing ½× TBE (25 mmol/L Tris, 25 mmol/L boric acid, 0.5 mmol/L ethylenediaminetetraacetic acid) buffer and run at 20 mA for 1.5 to 2 hours. The gel was then vacuum dried for autoradiography.

Results

Naturally occurring estrogen receptor mutations in T47Dco cDNA. Two independent cDNA libraries were constructed from the parental T47D line, T47Dco. Library 1 was made from total polyadenylated mRNA and yielded clones with the wild-type estrogen receptor sequence and several clones with mutant sequences. One mutant clone from this library was 0.9 kb in length, encoding part of exon 2 and all of exon 3. The mutant sequence has an insertion of two thymidine residues that changes amino acid 250 from methionine to isoleucine when compared with the wild-type sequence. The TT insertion results in a frame shift and the stop codon TGA is generated. Thus the protein resulting

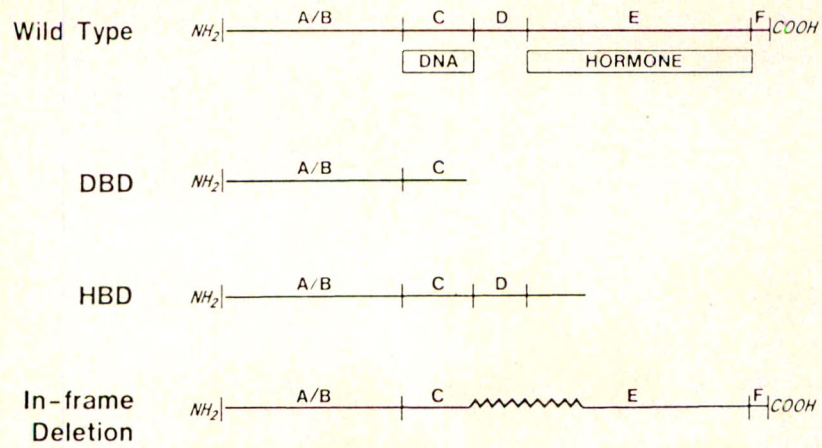

Fig. 1. Estrogen receptor forms isolated from T47Dco. Schematic representation of functional domains in wild-type estrogen receptor and the proteins encoded by mutant estrogen receptor cDNA of T47Dco cells. Functional regions of wild-type estrogen receptor (595 amino acids) include amino terminus domain *A/B*, DNA binding domain *C*, hinge region *D*, hormone binding domain *E*, and carboxy terminus *F*. Predicted structures of mutant proteins are also shown including DBD mutant truncated at amino acid 250, HBD mutant truncated at amino acid 417, and 153 amino acid in-frame deletion *(jagged line)* mutant.

from the translation of this message would be truncated after amino acid 250 in the DNA binding domain (domain C, DBD), just beyond the last cysteine (amino acid 245) of the second DNA-binding finger, and is designated the DBD mutant.

Library 2 also yielded clones with normal estrogen receptor sequences, as well as two types of mutant clones that are described here. The first mutant cloned from this library has undergone a single deletion of a guanine residue at amino acid 411 in the hormone binding domain of the receptor. The loss of this single base results in a frame shift and the generation of the stop codon TAG seven amino acids downstream from the mutation. Thus the protein encoded by this message would have an intact DNA binding domain and a normal hinge region (domain D); however, the hormone-binding domain would be truncated at amino acid 417. The last seven amino acids of the protein located downstream from the deletion would be novel and would not be present in the wild-type sequence. This clone has been designated the HBD mutant. The second library also yielded two independent clones of 820 and 980 nucleotides that have the identical deletion of 462 bp. The deletion occurs in-frame with the codons for the amino acids, and no frame shift occurs. These clones contain a wild-type upstream sequence from the 5′ untranslated region through the first four codons of exon 4. At this point the sequence is missing the next 462 nucleotides, including most of exons 4 and 5. The last codon of exon 5 is preserved, as are sequences in exon 6. These two independent clones would encode a 442-amino-acid mutant estrogen receptor protein instead of the native 595-amino-acid protein. The deletion includes part of the DNA binding domain, the entire hinge region, and a portion of the hormone-binding domain. This mutant has been designated the in-frame deletion. The T47Dco mutant cDNA clones have been reported previously,[8] and are shown schematically in Fig. 1 for reference.

Generation of a DBD mutant estrogen receptor expression vector and functional analysis of the mutant protein. We used site-directed mutagenesis to construct a pSG5 expression vector that contains the DBD mutant estrogen receptor sequence. The wild-type estrogen receptor pSG5 vector (HEGO-pSG5) was kindly provided by P. Chambon. The sequences of the wild-type and the DBD mutant estrogen receptor coding regions within the vector were verified by DNA sequencing (Fig. 2). These vectors were then transiently transfected into Cos-1 and HeLa cells by the calcium phosphate coprecipitation method. The cells were harvested and the whole-cell extracts were used to perform chloramphenicol acetyltransferase and gel mobility shift assays.

Fig. 3 shows the results of an assay testing the abilities of wild-type estrogen receptor and DBD mutant estrogen receptor to activate chloramphenicol acetyltransferase gene transcription. When the wild-type was transfected alone (lanes 1 and 2), conversion of ^{14}C-chloramphenicol to the acetylated products occurred in amounts significantly greater than the baseline conversion that occurred when the vit-tk-CAT vector was transfected alone (lanes 9 and 10). The DBD mutant transfection is seen in lanes 3 and 4. Chloramphenicol acetyltransferase activity by the DBD mutant was 7% increased over the baseline activity of the host cell in

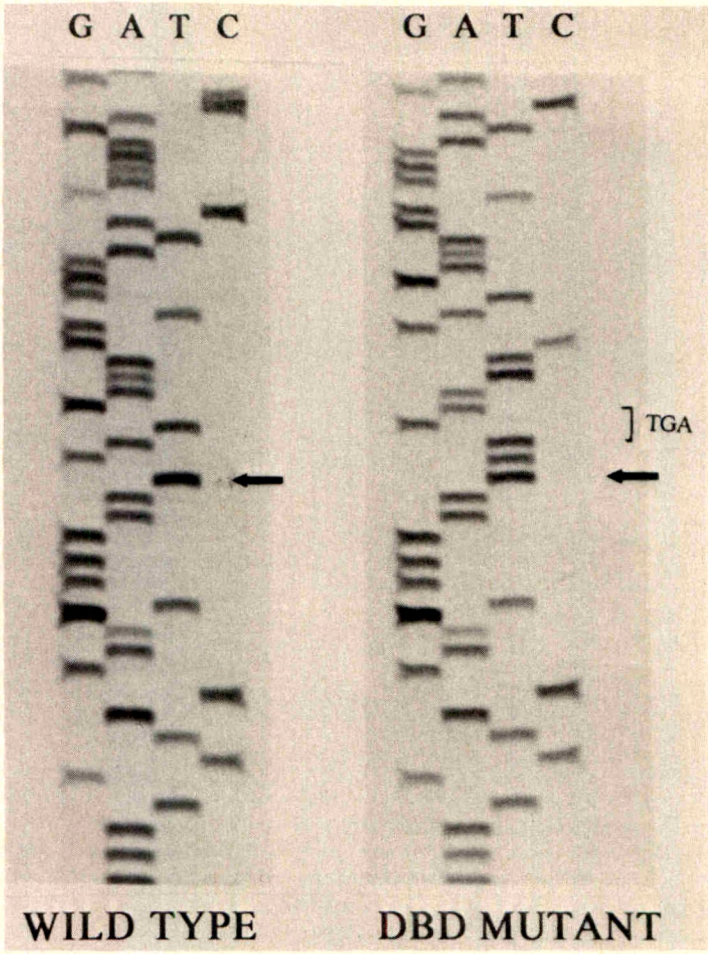

Fig. 2. Sequencing gel of wild-type and DBD mutant vectors. This figure provides proof of construction of DBD mutant. Wild-type estrogen receptor sequence is on left and DBD mutant is on right. *Arrow*, Compare with wild-type sequence. We successfully inserted two thymidine residues into DBD mutant sequence, like those originally found in naturally occurring clone. Two thymidine bases inserted generated frame shift and stop codon, TGA, which is also indicated here.

the absence of estrogen receptor. This finding was confirmed by densitometry measurements of the autoradiograph and by counting the ^{14}C-substrate and product from the thin-layer chromatography plate in a scintillation counter. Additionally, cotransfecting the DBD mutant and wild-type into the same cells (lanes 5, 6, 7, and 8) resulted in chloramphenicol acetyltransferase activity that may be slightly depressed compared with the activity of the wild-type alone. Thus, at the concentrations of DNA tested, the mutant appears to be capable of weakly activating gene transcription; also at very high concentrations ($\times 10$) it can slightly decrease wild-type gene activation.

To test the ability of the DBD mutant to bind to DNA, we used gel mobility shift experiments with a ^{32}P-labeled estrogen response element oligonucleotide.[15] Whole-cell extracts from cells transfected with wild-type or DBD receptor vectors were isolated and allowed to bind to the DNA. These receptor-DNA complexes were run on a polyacrylamide gel. If the extract contained functional estrogen receptors, the shifted bands that resulted from estrogen receptor binding to the estrogen response element were detected on an autoradiograph of the gel, and their estrogen receptor specificity was verified by antibody supershift.

Our experiments indicate that wild-type estrogen receptor binds strongly to the estrogen response element, resulting in three specific shifted bands. Several other nonspecific bands that result from protein-DNA interactions that are independent of estrogen receptor are also seen. The estrogen response element binding specificity of the protein-DNA complexes is confirmed by the fact that they can be competed by preincubating the cell extract with 100-fold excess of unlabeled estrogen response element, but are not competed by preincubation with 100-fold excess of the progesterone response element. The estrogen response specificity of the major band is confirmed by the fact that it is up-

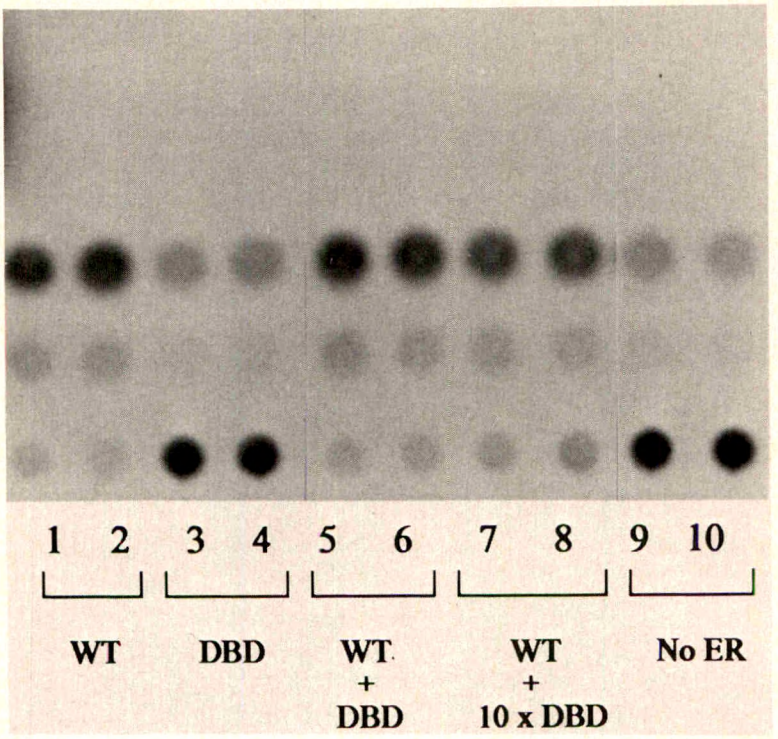

Fig. 3. Transcriptional analysis of wild-type and DBD mutant estrogen receptor. In chloramphenicol acetyltransferase assay substrate, ^{14}C-labeled chloramphenicol, is converted to its acetylated products only if enzyme chloramphenicol acetyltransferase is produced. Amount of product formed is a measure of chloramphenicol acetyltransferase gene transcription under control of estrogen receptor *(ER)*. Last two lanes of this gel show that little conversion of substrate to product occurs when estrogen response element–chloramphenicol acetyltransferase vector is transfected alone into Cos-1 cells, without estrogen receptor. We then compared choramphenicol acetyltransferace activity with that of wild-type *(WT)* estrogen receptor alone, as seen in *lanes 1 and 2;* with DBD mutant alone, *lanes 3 and 4;* and with cotransfection of both mutant and wild-type vertors, *lanes 5 to 8.*

shifted when the estrogen receptor antibodies H-222 and H-226 are added to the reaction mixture. H-222 recognizes an epitope in the hormone binding domain, while H-226 recognizes the DNA binding domain upstream from the site of the DBD truncation.[10]

Our results also confirm that little estrogen response element binding occurs when the DBD mutant is transfected alone. However, the addition of H-226 to the whole-cell extract and estrogen response element mixture does result in a faint, upshifted band that has the identical electrophoretic mobility as the wild-type H-222 upshifted band. Note that the epitope for H-222 would theoretically be missing in the DBD mutant. The significance of this band and whether it truly represents a supershifted estrogen receptor and estrogen response element complex that has resulted from DBD DNA binding remain unclear until expressed protein levels can be accurately quantitated. Cotransfecting the DBD mutant with wild-type estrogen receptors resulted in estrogen response element binding that appeared to be identical to that by wild-type estrogen receptors alone. However, a heterodimer would be difficult to detect under these conditions of extensive wild-type DNA binding. Note that in lane 14, with no transfected estrogen receptors, a nonspecific band migrated in a position similar to that of the major specific estrogen receptor band. This can also be seen in lanes 3, 7, and 12 to which cold specific estrogen response element DNA has been added, indicating that this band is nonspecific. Adding H-222 estrogen receptor antibody to the lane without estrogen receptor does not result in a supershifted band (data not shown).

Comment

The molecular biologic characteristics of the estrogen receptor have been extensively explored in recent years. The cDNA was independently cloned and sequenced from MCF-7 breast cancer cells by two groups in 1986, Green et al.[9] and Greene et al.[11] The protein is encoded by a 6322-nucleotide mRNA. On the basis of this work, Kumar et al. distinguished six functional domains of the receptor.[10, 15] The domains are identified by the letters A through F. The C domain contains two DNA-binding zinc fingers and is the region of the pro-

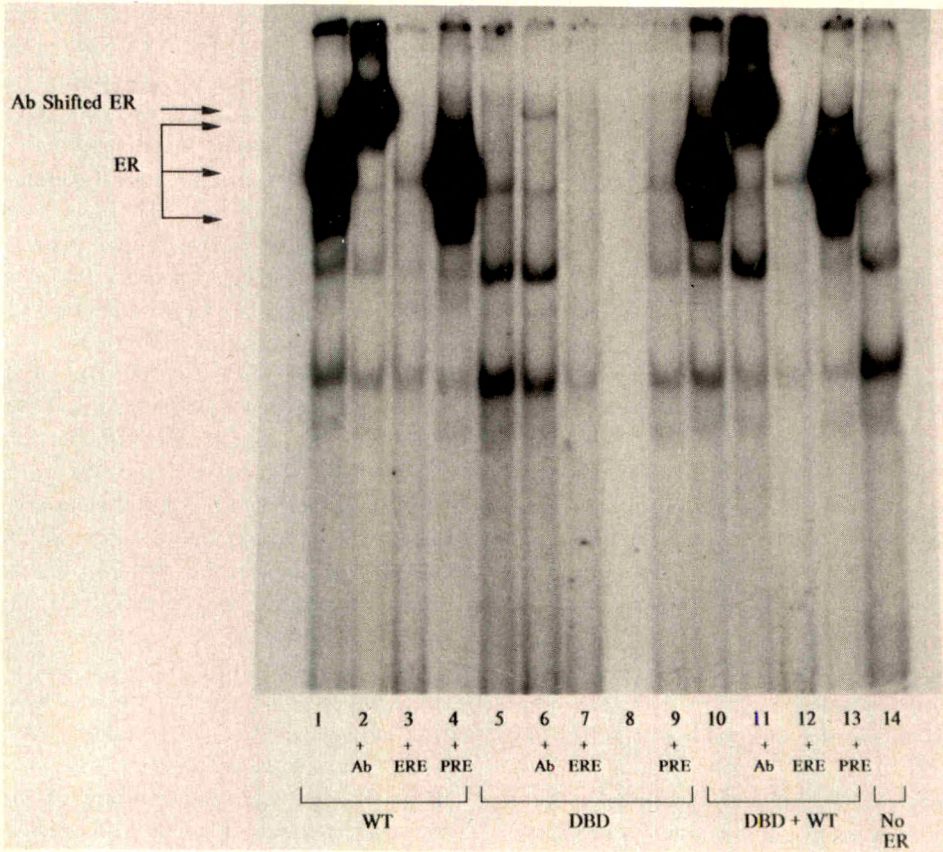

Fig. 4. Gel mobility shift assay of wild-type *(WT)* and DBD mutant estrogen receptor *(ER)* binding to estrogen response element *(ERE)*. *Lane 1* has shifted bands that result from interaction of HeLa whole-cell extract containing wild-type estrogen receptor with estrogen response element DNA. *Lane 2* shows supershifted band that has resulted from addition of estrogen receptor antibody H-222. Some nonspecific shifted bands that have resulted from protein-DNA interactions that are not related to estrogen receptor are also shown. *Lane 3* shows that specific estrogen receptor–shifted band can be competed out by addition of 100-fold excess of unlabeled specific estrogen response element DNA. Unlabeled estrogen response element DNA has displaced estrogen receptor from labeled estrogen response element; however, nonspecific shifted bands are still present. In *lane 4* 100-fold excess of unlabeled nonspecific DNA has been added. In this case progesterone response element *(PRE)* has been used, which does not bind estrogen receptor. *Lanes 5, 6, 7, and 9* represent identical experiment with DBD mutant protein and H-226 anti–estrogen receptor antibody. *Lane 8* is blank. *Lanes 10 to 13* represent estrogen receptor binding when wild-type and DBD mutant are cotransfected into same cells. In *lane 14* cells have been transfected with expression vector lacking the estrogen receptor cDNA insert.

tein that binds to the estrogen response element. Mutations in this portion of the protein were shown to change the affinity of the protein for DNA, resulting in suboptimal or complete loss of DNA binding. The hormone binding capability of the receptor resides in region E, and mutations in this region affect the ability of the receptor to bind ligand. Because these two functions, DNA binding and hormone binding, are carried out by separate parts of the protein, they are to some extent independent. Thus it appears to be possible to have variant receptors that can bind to DNA with limited affinity without first binding hormone and vice versa.[10]

Reports of naturally occurring mutant or variant estrogen receptor forms have recently appeared in the literature. Several polymorphic forms of the estrogen receptor gene have been described.[16-18] The majority of these genetic changes have occurred in introns, which do not directly encode the mRNA or, in turn, the protein. However, several exon mutations have also been found. Garcia et al.[19] identified a mutation in the B region of estrogen receptor mRNA in some human breast cancer biopsy specimens that represents a polymorphic variant estrogen receptor form. This mutation has since been correlated with lower than normal levels of hormone binding.[20] Preliminary evidence suggests that women who are heterozygous for this mutation

have a higher proportion of spontaneous abortions than those who are homozygous at the same locus.[21]

Estrogen receptor mRNAs from several tissues and species are reported to be the same size: 6.3 kb.[22] However, Murphy and Dotzlaw[23] have identified smaller-sized estrogen receptor–like mRNAs in human breast cancer biopsy samples by Northern blotting. Some of these smaller-size messages appear to lack significant portions of the 3′ region of the message, including the hormone binding domain. Fuqua et al.[24] have also identified a mutant form of estrogen receptor that is missing part of the hormone binding domain (exon 5) by polymerase chain reaction amplification of mRNA from tumor specimens. This mutant is an alternatively spliced form that is capable of constitutively activating transcription of a normally estrogen-dependent gene construct in yeast cells. Polymerase chain reaction amplification was also used to identify a mutation in the D domain of estrogen receptor mRNA expressed in a murine transformed Leydig cell line, B-1 F.[25] The functional significance of these mutations has yet to be fully explored.

Our investigations of the T47Dco breast cancer line have determined that T47Dco expresses mutant estrogen receptor mRNA that may encode anomalous proteins. We are interested in the functional significance of these putative proteins. Do these mutants explain the heterogeneity and estradiol-resistant phenotype of the parental cell line? Can the mutants bind to DNA? Do they dimerize with other estrogen receptors? Can they activate gene transcription?

To begin to address these questions, we are constructing the mutant estrogen receptors by site-directed mutagenesis. Preliminary data for the DBD mutant are described here. We have shown that this protein has some capacity to bind to DNA and to activate gene transcription with gene mobility shift (Fig. 4) and chloramphenicol acetyltransferase assays (Fig. 3). Furthermore, in cotransfection experiments, the DBD mutant may not significantly interfere with the ability of the wild-type receptor to bind to DNA on gel shift, although it slightly decreases chloramphenicol acetyltransferase activity. Additionally, the lack of an intermediate-sized shifted band in cotransfected cells (Fig. 4) suggests that no heterodimers form between the DBD mutant and wild-type receptor. Considering the structure of the mutant, these results are not surprising.

On the basis of an analysis of the domains of the wild-type estrogen receptor and a series of extensively tested truncation mutants constructed by Kumar et al.[10, 15] the functional capabilities of the DBD mutant can be predicted. This protein is truncated after amino acid 250 within the DNA binding domain; as a result, its DNA binding capabilities are expected to be greatly diminished. The entire hormone binding domain is missing, which effectively precludes ligand binding. Thus the very low level of DNA binding that may occur, as evidenced by the faint supershifted band shown in Fig. 4 in the presence of the estrogen receptor antibody H-226, must be hormone independent.

What would be the theoretical consequences of the expression of such a protein? Cells may demonstrate a chronic; low level of constitutive expression of estrogen-dependent genes; that is, estrogenic responses would be up-regulated in the absence of estradiol—a classic estrogen-resistant scenario.

Theoretically, a mutant like the DBD protein can squelch the normal estrogen receptor even if it has no capacity to stimulate transcription as a homodimer or to form heterodimers with wild-type estrogen receptor. The mutant may bind up transcription factors that are needed by the functional receptor and thereby limit its normal transcriptional activity. Squelching is a subset of a dominant-negative activity that may lead to an estrogen-resistant state.

We have shown that T47Dco breast cancer cells express mutant estrogen receptor mRNAs that may encode abnormal estrogen receptor proteins. In additional experiments we have reconstructed one of these naturally occurring mutants, the DBD estrogen receptor and have begun to analyze its functional characteristics. Future experiments will address the activity of the HBD and the in-frame deletion mutants in an attempt to understand and account for the estrogen-resistant T47Dco phenotype. Our data, along with the work of others, support the possibility that functional and nonfunctional estrogen receptor mutant proteins may be present in some cells. The significance of these findings with respect to the prognosis and treatment of breast and endometrial cancer and as well as the possible role of mutant estrogen receptors in the pathogenesis of other obstetric and gynecologic problems, such as recurrent pregnancy loss, await further elucidation.

We thank Drs. Pierre Chambon and Andrew Baker for sending us the necessary vectors. Drs. Lin Tung, Glenn Takimoto, Nancy Krett, Mark Graham, Bill Wood, David Gordon, and Louise Miller have made suggestions and provided us with assistance during this work. Kate Strand provided technical support. Abbott Laboratories kindly provided antibodies H-222 and H-226.

Laser surgery–operative laparoscopy: Technology assessment

Laser surgery–operative laparoscopy panel

Introduction

It has become apparent that innovations in medicine are frequently expensive, inadequately studied, aggressively promoted, and, perhaps, prematurely incorporated into clinical practice. Two years ago the American Gynecological and Obstetrical Society decided to sponsor each year at this meeting a thorough critique of a new or controversial test, procedure, or treatment. The participants are chosen from the membership of the Society as individuals who will objectively evaluate the literature and who have no personal or vested interest in the outcome or conclusion.

Frontiers of operative laparoscopy: A review and critique of the evidence

David A. Grimes, MD
Los Angeles, California

OBJECTIVES: This report reviews the evidence supporting the use of operative laparoscopy for a number of expanded indications in gynecology.
STUDY DESIGN: Studies published in English were identified through a Medline search back to 1966 for literature listed under the medical subject heading of "peritoneoscopy"; this search was supplemented by reviews of reference lists and discussions with experts.
RESULTS: Fair evidence exists to recommend use of laparoscopy for ectopic pregnancy, ovarian biopsy, and treatment of polycystic ovarian syndrome resistant to clomiphene citrate therapy. Evidence concerning other indications is inadequate to allow recommendations.
CONCLUSION: Mechanisms are urgently needed to evaluate surgical innovations in gynecology with the same degree of scientific rigor currently afforded medical innovations. Without surgical technology assessment, the current double standards in gynecologic therapy will persist. (Am J Obstet Gynecol 1992;166:1062-71.)

Key words: Laparoscopy, peritoneoscopy, ectopic pregnancy

Imagination and daring must be coupled with a healthy coefficient of skepticism.[1]

In recent years the uses for the laparoscope in gynecology have expanded dramatically from diagnosis and tubal sterilization to treatment of ectopic pregnancy and ovarian neoplasms. The 1988 membership survey of the American Association of Gynecologic Laparoscopists[2] provides an index of the frequency of these newer uses. Although only 24% of the questionnaires were returned with usable responses, 880 physicians reported having performed 36,928 newer procedures in that year (Fig. 1), including >5000 cases involving ovarian cysts and >4000 procedures to destroy the uterosacral nerves.

However, the safety and efficacy of these expanded uses for operative laparoscopy compared with that of laparotomy remain largely unknown. In the Association's survey[2] the reported serious complication rate was 15 per 1000 procedures; the mortality rate was 5 per 100,000 procedures. On the basis of limited information, some enthusiasts have proclaimed that "The obituary of laparotomy for pelvic reconstructive surgery has been written . . .,"[3] while others have cautioned that "To depict a 4-hour endoscopic marathon as prog-

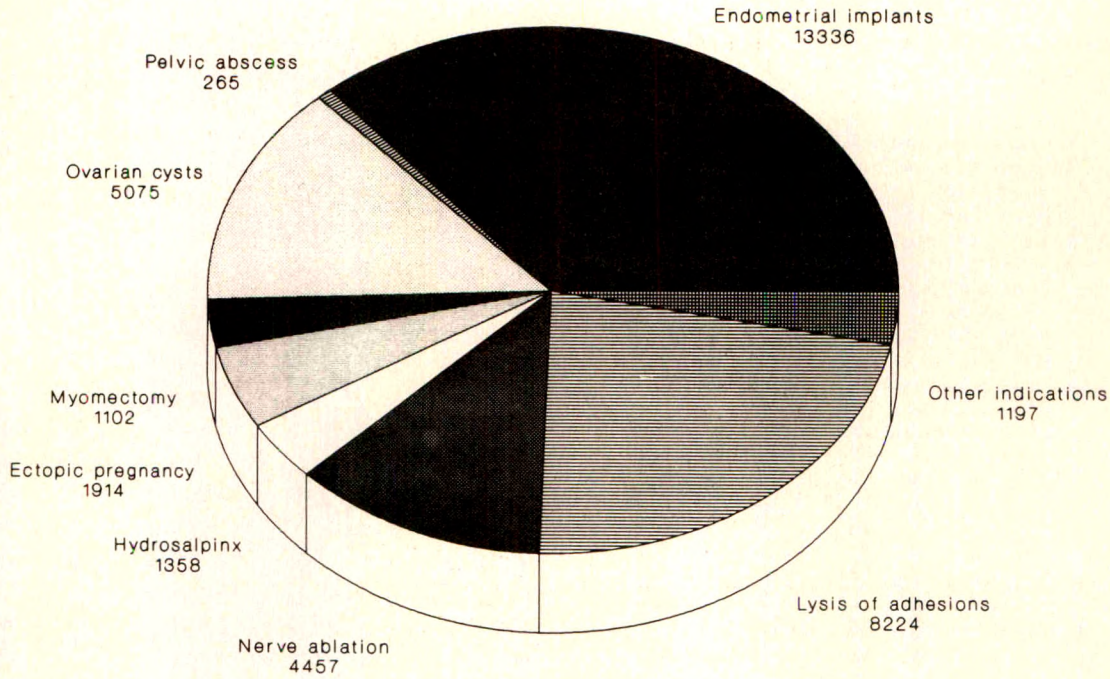

Fig. 1. Number of operative laparoscopies by indication performed by 880 members of the American Association of Gynecologic Laparoscopists (1988).[2]

ress when the same result could have been achieved by laparotomy within 2 hours is ludicrous."[4] The field of operative laparoscopy is now populated by both "kamikaze surgeons who will push the bounds of this surgery to the outer limits" and physicians who "remain as maladroit as a beetle on its back and should stay with conventional techniques."[4]

Operative laparoscopy has several potential advantages over conventional laparotomy. Operating times may be shorter for some procedures, and postoperative recovery is faster.[5] Adhesion formation may be less likely.[6] Shorter hospital stays may translate into substantial economic advantages.[7] As pointed out in a thoughtful review, "The crucial question, however, is whether the results are equivalent to those of laparotomy."[8] My article attempts to address this question by evaluating the literature on some emerging roles for operative laparoscopy.

Material and methods

This review included management of ectopic pregnancy, ovarian biopsy, treatment of ovarian cysts, adnexectomy, treatment of polycystic ovary syndrome, management of pelvic abscess, uterosacral nerve ablation, ventrosuspension of the uterus, and hysterectomy. Laparoscopic management of endometriosis or infertility and treatment with intraabdominal lasers (covered elsewhere in this symposium) were excluded from consideration.

To identify relevant publications I conducted a Medline search back to 1966 for literature listed under the medical subject heading of "peritoneoscopy." I also consulted reference lists in textbooks as well as those of articles retrieved through the Medline search. These were supplemented by reviews of syllabus references from Association-sponsored courses and discussions with experts in the field. My review was restricted to reports in English. Although a number of papers have been published in French and German, most of them appeared to be descriptive studies similar to those published in English.

I categorized each report by type of study, grouped reports by indication for operative laparoscopy, and evaluated the quality of the evidence supporting the use of laparoscopy for that indication. For this evaluation I adapted the United States Preventive Services Task Force rating scale[9] (Table I), which was modified from a method developed by the Canadian Task Force on the Periodic Health Examination.[10] This hierarchy of studies gives greater weight to those studies that are, in general, less subject to bias and misinterpretation. Randomized controlled trials were accorded the greatest weight, cohort and case-control studies (analytic studies) or comparisons between time and places intermediate weight, and case-series and case reports (descriptive studies) or expert opinions the least weight.

In addition to categorizing study types, I also evaluated the quality of the research methods. Because none of the published randomized controlled trials could be considered to have been properly designed,[9] each study was considered class II evidence. Similarly, unless cohort and case-control studies were well

Table I. Quality of evidence

I	Evidence obtained from at least one properly designed randomized controlled trial.
II-1	Evidence obtained from well-designed controlled trials without randomization.
II-2	Evidence obtained from well-designed cohort or case-control analytic studies, preferably from more than one center or research group.
II-3	Evidence obtained from multiple time series with or without the intervention. Dramatic results in uncontrolled experiments (such as the results of the introduction of penicillin treatment in the 1940s) could also be regarded as this type of evidence.
III	Opinions of respected authorities, based on clinical experience, descriptive studies, or reports of expert committees.

Source: United States Preventive Services Task Force.

Table II. Strength of recommendations

A	There is good evidence to support the recommendation that operative laparoscopy be used for this indication.
B	There is fair evidence to support the recommendation that operative laparoscopy be used for this indication.
C	There is inadequate evidence regarding the use of operative laparoscopy, for this indication, but recommendations may be made on other grounds.
D	There is fair evidence to support the recommendation that operative laparoscopy not be used for this indication.
E	There is good evidence to support the recommendation that operative laparoscopy not be used for this indication.

designed[9] they were considered class III evidence. Case-series reports, the most frequent study design, were judged class III evidence. This modification of the classification scheme[9] was used to incorporate both the type and quality of evidence available for making clinical recommendations.

Using a five-point rating scale (Table II), I assessed the strength of the recommendation that can be made concerning each use of operative laparoscopy based on the existing evidence. This scale was modified from that used by the United States Preventive Services Task Force.[9] Indications for which laparoscopy has been proved safe and effective in well-designed studies (class A) were recommended. Similarly, uses for which laparoscopy has consistently been shown to be safe and effective in a large number of studies of lesser merit (class B) were recommended. Those uses that have been shown to be unsafe or ineffective (classes D and E) were not recommended. When evidence was insufficient in quality or quantity to make a recommendation (class C), none was made.

Results

Ectopic pregnancy. Ectopic pregnancy has been more thoroughly studied than other expanded indications for operative laparoscopy (Table III). Two groups of investigators have evaluated management of ectopic pregnancy in randomized controlled trials. In a study of 60 patients with unruptured tubal pregnancies, Vermesh et al.[11] randomized half to undergo salpingostomy by laparoscopy and half by laparotomy. Three patients (10 per 100 procedures) in each group sustained complications; the group having laparoscopy had significantly shorter hospital stays and recuperations. However, as noted by the authors, the power of this trial to detect important differences in outcomes was very low. To show that laparoscopy was associated with a 50% reduction in morbidity (α 0.05, power 80%, and equal numbers of subjects in both groups), 948 patients would be required.

In a similar study by Lundorff et al.,[6] 73 patients underwent a second laparoscopy to evaluate adhesion formation after treatment for ectopic pregnancy. In the group having had prior laparoscopic treatment, the ipsilateral tube had adhesions less often (42 per 100) than in the group having had laparotomy (76 per 100; relative risk 0.5; 95% confidence interval 0.3 to 1.0). The rates of tubal patency were not significantly different. The comparison was biased because the two groups had different operations performed on the tubes. Moreover, 30% of subjects initially randomized were not evaluated and rates of follow-up were substantially different for the two treatment groups, raising the possibility of ascertainment bias.

Two groups of investigators compared laparoscopy with laparotomy in cohort studies. Brumsted et al.[12] performed a retrospective cohort study that they incorrectly characterized as a case-control study. The rate of operative complications was identical in the two groups (8 per 100 procedures), although the group undergoing laparoscopy had more serious complications: one wound abscess and one failed evacuation versus two cases of urinary retention. In a similar study design, Lundorff et al.[13] compared the rates of persistent trophoblast after these two surgical approaches. The rate was 10 per 100 procedures with laparoscopy versus 7 per 100 with laparotomy (relative risk 1.5; 95% confidence interval 0.4 to 5.8). Again, small sample size severely limited the power of this study. To demonstrate a 50% higher rate of persistent trophoblast in the group treated with laparoscopy (α 0.05, power 80%, and equal allocation of subjects), 2338 subjects would be required.

Numerous descriptive studies[14-33] have been published. These include both case-series reports (Table III) and case reports.[34-36] The patients described in Table III overlap; therefore, the numbers of cases can-

not be aggregated for analysis. Overall, the rates of complications were low, usually 4 to 5 per 100 procedures. The most frequent complications were failure to evacuate the products of conception, hemorrhage requiring a different or repeat operation, and persistent trophoblast requiring repeat operation or methotrexate treatment. The highest reported rate of persistent trophoblast was 14%.[33]

Operative laparoscopy has also been used to treat ectopic pregnancies in uncommon loci. Both Hill et al.[37] and Reich et al.[26] have treated interstitial ectopic pregnancies, and others[38, 39] have managed ovarian pregnancies with the laparoscope.

The quality of evidence to date concerning this indication for operative laparoscopy is class II-2. Neither of the two randomized trials met the requirements for reporting such studies,[40-43] and neither had sufficient power to demonstrate potentially important differences. There is fair evidence (class B) to recommend that operative laparoscopy be used to treat ectopic pregnancies, although the four comparative studies[6, 11-13] suggest that the short-term safety and efficacy are similar or inferior to that of laparotomy. Laparoscopic treatment has not been shown to result in fewer adhesions or higher tubal patency rates than treatment by laparotomy.[44] Long-term follow-up studies and comparisons of laparoscopy versus injection of ectopic pregnancies with methotrexate or prostaglandin are needed.

Ovarian biopsy. Biopsy of the ovary was one of the earliest indications for operative laparoscopy, and a flurry of reports appeared in the early 1970s. One retrospective cohort study[45] described substantial morbidity. It compared the combination of diagnostic lapa-

roscopy with ovarian biopsy, tubal patency studies, and endometrial biopsy in 75 patients versus the same procedures without ovarian biopsy in another 75 patients. The relative risk of being hospitalized longer than 24 hours was 2.9 (95% confidence interval 1.3 to 6.4) for the group having ovarian biopsy. In addition, several serious complications occurred in the group undergoing biopsy, including one transected ureter and one infected hematoma.

Nine case-series reports[46-54] have described ovarian biopsies in 770 patients. Complication rates ranged from 0 to 5 per 100 procedures. Most of these complications were hemorrhage, although one report of 39 patients[51] described a ureterovaginal fistula after an unsuccessful attempt to perform a biopsy of a streak gonad. Two cases of tumor implantation at the laparoscopy site after biopsy of a serous ovarian tumor of low malignant potential have occurred.[55] The quality of evidence concerning laparoscopic ovarian biopsy is class III, and there is fair evidence (class B) to recommend operative laparoscopy for this indication. Nevertheless, the aggregate rate of ureteral injury appears to be about 2 per 1000 procedures, similar to that reported for adnexectomy performed by laparotomy (1 per 1000).[56]

Treatment of polycystic ovary syndrome. Several groups of investigators have traumatized ovaries in the hopes of reproducing the beneficial effect of wedge resection without the attendant risk of postoperative adhesions. One randomized controlled trial[57] compared ovarian electrocautery with either human menopausal gonadotropins or pure follicle stimulating hormone as therapy. The rate of ovulation was equal (71 per 100 procedures) in the groups receiving treatment with cautery or human menopausal gonadotropin. This trial failed to meet many of the reporting requirements for such studies, and it lacked sufficient power to have identified a twofold difference in rates of ovulation between treatments.

One cohort study[58] compared the endocrine response of six women with ovarian cautery versus that of six who were subjected to laparoscopy without ovarian cautery. Androstenedione, testosterone, estradiol, and luteinizing hormone levels decreased after surgery in the group receiving cautery but not in the controls.

Several case-series reports[59-66] ranging in size from 9 to 85 patients have reported ovulation rates of 45% to 92% within 3 months after the operation. The lowest rate[59] was obtained after ovarian resection (multiple biopsies) as opposed to cautery or laser vaporization in the other reports. These reports also corroborate improvements in levels of androgens and gonadotropins after treatment. Long-term effects await further study. No early complications were reported, but a small proportion of patients were later found to have ovarian adhesions.[60,67] Finally, one case-series report[68] described no apparent adverse effects on pregnancies conceived after ovarian electrocautery. The quality of evidence for this indication is II-2, and there is fair evidence (class B) to recommend use of laparoscopy to treat polycystic ovary syndrome that is refractory to therapy with clomiphene citrate.

Adnexal operations unrelated to ectopic pregnancy. One retrospective cohort study[69] compared laparoscopic salpingectomy, salpingostomy, oophorectomy, and ovarian cystectomy in 330 patients with similar operations by laparotomy in 129 patients. Included in the laparoscopy group were 98 women having salpingectomy or oophorectomy for indications other than ectopic pregnancy; the complication rate was 9 per 100 procedures. Comparable morbidity data were not provided for the group having laparotomy. Both selection and ascertainment bias appear likely in the study. Overall operating times were similar for both groups, although those undergoing laparoscopy had significantly shorter hospital stays and recuperation periods.

Several case-series reports[70-74] confirm the feasibility of adnexectomy via laparoscopy. In these reports, which range in size from 8 to 100 patients, the complication rates varied from 0 to 18 per 100 procedures.[70,73] Complications included burns, wound infection, hematoma, hemorrhage, and brachial plexus injury. One report[72] described successful laparoscopic treatment of adnexal torsion in 77% of 35 patients. In addition, a recent case report[75] has documented removal of streak gonads in a patient with gonadal dysgenesis. The quality of evidence for this indication is class III, and there is insufficient evidence to recommend laparoscopy for this indication (class C).

Ovarian cysts. Management of ovarian cysts is one of the most common and controversial applications of operative laparoscopy. Problems with this technique include the inadequacy of cytologic diagnosis of aspirated cyst fluid, recurrence of cysts, and the potential for disseminating or delaying the diagnosis of ovarian cancer. The case-series reports to date,[76-83] ranging in size from 9 to 420 patients, have not resolved these issues.

In an early series of 71 patients, Kleppinger[76] reported a recurrence rate of 33 per 100 procedures when only aspiration was performed, in contrast to zero when fenestration of the cyst capsule was done ($p < 0.01$ by Fisher exact test). In a series of 19 patients Larsen et al.[77] revealed the potential for missing ovarian cancer. They aspirated a cyst from an ovary in a 40-year-old who 7 months later was found to have a serous cystadenocarcinoma in the same ovary. Another patient had a dermoid cyst open accidentally during surgery and required readmission for abdominal pain 1 week later; the complication rate in this series was 11 per 100 procedures. Magos et al.[78] reported a complication rate of 6 per 100 procedures (one laparotomy because

of a technical failure). In a series of nine patients with dermoid cysts, Nezhat et al.[79] reported no complications, although three patients required colpotomy to remove large cysts.

Hasson[80] noted a recurrence rate of 13 per 100 procedures; the likelihood of recurrence of endometriomas varied with surgical technique. With fenestration alone 8 of 9 (89 per 100 procedures) cysts recurred in contrast to 2 of 18 (11 per 100) with fenestration plus coagulation or resection of the cyst lining (relative risk 8.0, 95% confidence interval 2.1 to 30.2).

The largest series to date[81] documented a low complication rate with cystectomy (1 per 100 procedures); complications included two cases of ovarian abscess. These authors found a high sensitivity but low specificity for identifying ovarian cancer with laparoscopy. In a pilot study of operative laparoscopy for cysts in carefully selected postmenopausal women, Parker and Berek[82] noted a complication rate of 12 per 100 procedures, including one injury to the bladder and one to the colon.

The most worrisome report,[83] however, stems from a survey of oncologists concerning laparoscopic excision of ovarian neoplasms that were later discovered to be malignant. Twenty-nine respondents reported 42 such cases. Laparotomy was delayed in 71% of cases, with a mean interval of 5 weeks. Half of these patients had stage II or greater disease. In five cases exploratory laparotomy was never done. One respondent documented a 9-hour attempt to perform cancer staging by laparoscopy.

The quality of evidence concerning management of ovarian cysts is class III, and the evidence is insufficient (class C) to make a recommendation concerning this indication. Operations in which the cyst fluid is drained but the cyst is not submitted for histologic examination can compromise the care of patients with unsuspected ovarian cancer.

Pelvic abscess. Although laparoscopy has long been the standard for diagnosis of salpingitis, few investigators have explored its potential usefulness as treatment. Three small case-series reports[84-86] have described laparoscopy to drain pelvic abscesses and to break up loculations of pus. Ninety-five patients underwent such procedures without reported complications related to the laparoscopy. The quality of evidence concerning this indication is class III, and there is insufficient evidence (class C) to recommend the use of laparoscopy for this purpose. If laparoscopic treatment of pelvic abscesses is subsequently found to have merit, this benefit will have to be balanced against the additional costs and risks related to the operation.

Laparoscopic uterosacral nerve ablation. Prompted by the favorable experience of Doyle[87] with transection of the uterosacral nerves as treatment for refractory dysmenorrhea, two reports have described nerve ablation at laparoscopy. One study[88] of 21 patients without organic pathologic conditions found an improvement in symptoms lasting up to 1 year among women who had ablation by cautery. No benefit was seen among women who had only diagnostic laparoscopy ($p = 0.04$, Fishers two-tailed test). No complications were reported. Although the report claimed to be a double-blind trial, the randomization process was not random, and the allocation was not blind. Hence, this study should be considered a prospective cohort study.

The same author[89] reviewed his experience with 54 such transections; 32 patients (59 per 100 procedures) reported "significant" improvement in symptoms. It is unclear whether subjects in the randomized trial[88] were included in this case-series report. In addition, one case-series report[90] described "laser neurectomy" via laparoscopy in 12 women. The success rate was not specified for this group, although in the total group of 42 patients 71% had little or no dysmenorrhea 1 year after operation. The complication rate was not specified. Nevertheless, at least one ureter has been severed as a complication of coagulation and transection of the uterosacral ligaments in a patient with no pelvic pathology.[91] The quality of evidence for this indication is class II-2, but there is insufficient evidence (class C) to recommend the use of laparoscopy for this purpose.

Ventrosuspension of the uterus. Suspension of the uterus has been suggested as therapy for deep dyspareunia and chronic pelvic pain associated with retroversion. In one case-series report,[92] 72 patients had laparoscopic suspension performed by lifting the round ligaments out of the abdomen and suturing them to the anterior rectus fascia. Only 26% of patients with follow-up at 6 months reported benefit, and the complication rate was 39 per 100 procedures. Complications included 19 cases (30 per 100 procedures) of persistent groin pain and six (9 per 100) wound infections. An earlier case-series report[93] described the outcomes of 100 cases of ventrosuspension. The success rate was high (89 per 100 procedures) and the morbidity rate low (9 per 100). Nevertheless, the median number of days spent in the hospital was 5. The quality of evidence for this indication is class III, and there is insufficient evidence (class C) to make a recommendation regarding this use.

Other applications. Several other uses for operative laparoscopy have been explored. One case-series report[94] has described myomectomy without complications in 17 patients previously treated with gonadotropin-releasing hormone analogs. One case report[95] has documented resection without complications of a noncommunicating rudimentary uterine horn. Two groups[96,97] have published reports of "laparoscopic hysterectomy" in which most of the operation was per-

formed by laparoscopy. In both, however, the procedure was completed by the vaginal route. Because operating times ranged from 90 to 180 minutes, the benefit of this approach as compared with vaginal hysterectomy is not apparent. On the other hand, laparoscopy may be useful in identifying appropriate candidates for vaginal hysterectomy.[98] The quality of the evidence concerning these indications is class III. There is insufficient evidence (class C) to recommend the use of laparoscopy for myomectomy, resection of a noncommunicating uterine horn, and hysterectomy.

Comment

The literature concerning expanded indications for operative laparoscopy consists primarily of descriptive studies. Very few randomized controlled trials or analytic studies have been performed; those that have been done have methodological shortcomings, including low power. Because of these limitations, whether these operations are preferable to laparotomy remains unknown.

A double standard prevails today in gynecologic therapy. Although elaborate clinical trials are required before the use of new pharmaceuticals, comparable scrutiny is not required before new operations are adopted and disseminated. A scientific process determines what medicines our patients may receive; competitive marketing, opinion, and uncontrolled human experimentation determine what operations they may receive. Unnecessary trial and error is particularly troubling in surgery because, unlike a medicine, an operation cannot be withdrawn after it has been administered to a patient.[99]

The recent proliferation of uncontrolled experimentation with operative laparoscopy highlights the need for systematic assessment of new surgical technologies. Many thousands of operative laparoscopies are being performed annually[2] in the absence of solid evidence that they are preferable to other surgical alternatives. As observed by one ethicist, "If a study of the history of medicine reveals anything, it reveals that clinical judgment without the check of scientific controls is a highly fallible compass."[100]

Operations come and go. If they "graze" on the medical commons too long, they may squander valuable time and resources that could have been devoted to worthwhile surgery.[101] Examples of operations performed during this century that were accepted as standards of care yet were ultimately discarded as worthless include colectomy for epilepsy, renal capsule stripping for acute tubular necrosis, surgical correction of ptosis of the internal organs, and operations to remedy constipation.[101, 102] Similarly, hysterotomy and hysterectomy for elective abortion were abandoned in the United States when analytic studies showed them to be inferior to alternative techniques.[103]

Critical appraisal of new operations can help us to avoid repeating these errors. Although some[104, 105] have argued that formal trials are impractical and would impede innovation, these criticisms lack merit. As noted by a distinguished panel of scientists, "There is no scientific or humanistic reason why standards for acceptance should not be equal for all treatments. On the contrary, science and ethics demand our best efforts for equal standards."[106] Clearly, the best effort is the randomized trial.

After the initial feasibility of a new procedure has been demonstrated multicenter, collaborative trials should be started with uniform protocols and outcome measures. Professional societies should initiate and conduct such studies. For example, trials performed under the auspices of the Gynecologic Oncology Group have made important contributions to our management of cancer. Clinical trials, however, can be challenging: it may take years to recruit adequate sample sizes, multiple centers may need to participate, and the costs can be large. If a new operation is shown to be safe and effective, general use could begin with provision for continued surveillance of outcomes and complications as the operation's use grows (analogous to postmarketing surveillance of drugs).[107]

Future research should compare laparoscopy not only with traditional laparotomy but also with other alternatives, such as minilaparotomy or colpotomy. For example, many ectopic pregnancies can be easily managed through a 3 cm abdominal incision with the assistance of a uterine elevator. Alternatively, if the gynecologist must perform a colpotomy to remove an adnexal cyst after dissection with the laparoscope, the possibility of conducting the entire operation through a colpotomy incision warrants evaluation. Many cysts can be deflated and removed vaginally.

The adoption of new technologies often follows a sine-wave curve. Operative laparoscopy is currently on the ascending slope, and enthusiasm may have outpaced critical evaluation. Laparoscopy has unquestionably made important contributions to women's health in the past and will likely continue to do so. Technology assessment, however, is urgently needed to define that future role. If physicians do not provide technology assessment, other interests are likely to do so. In the interim, Gomel's "healthy coefficient of skepticism"[1] must remain high: a 9-hour staging laparoscopy for ovarian cancer is unlikely to be in the best interests of the patient. That an operation can be done through a telescope does not imply that it should be.

Infertility and endometriosis: Comparison of pregnancy outcomes with laparotomy versus laparoscopic techniques

Norman F. Gant, MD
Dallas, Texas

OBJECTIVES: The null hypothesis of this retrospective literature analysis was that the superiority of laparoscopy over laparotomy to correct infertility resulting from tubal injury has not been proved because of the lack of well-designed comparative studies. The same was true for the correction of infertility caused by minimal and mild endometriosis.
STUDY DESIGN: A retrospective review of the English-language literature since 1975 was made to ascertain whether laparoscopic surgical correction of infertility caused by tubal injury and endometriosis resulted in an increased pregnancy rate compared with laparotomy techniques. Complication rates associated with laparoscopy versus laparotomy were also compared.
RESULTS: There were almost no adequate studies designed and executed to answer these questions based on criteria established by the United States Preventive Services Task Force. Furthermore, there was no evidence in the reported series that laparoscopic surgical procedures were superior to laparotomy in correcting infertility. The complication rates were similar. There was suggestive, but not yet proven, evidence that laparoscopic surgery with laser techniques may be superior to laparotomy in the management of infertility resulting from moderate and severe endometriosis.
CONCLUSION: Although results and complications were similar, the cost in savings with respect to decreased hospital expenses and loss of work time favor the use of laparoscopy over laparotomy when results are similar and not associated with increased risk. What has not been established are costs and work-time losses for minilaparotomy compared with laparoscopy. (Am J Obstet Gynecol 1992;166: 1072-81.)

Since the first laparoscopic excision of an ectopic pregnancy, the indications and uses for laparoscopies have increased dramatically. New surgical instruments are available, and videoscopic pictures now allow the surgeon's assistants to observe the operative field and more ably assist the surgeon. The advent of laser techniques have added newer and, it is hoped, better and more useful destructive and dissection tools to the surgeon's armamentarium. These truly remarkable surgical tools have found a receptive clinical audience and widespread clinical use. The recently published survey of the membership of the American Association of Gynecologic Laparoscopics[1] contained a summation of responses from 880 physicians representing approximately 24% of the membership. These physicians performed 36,928 laparoscopic procedures during 1988. A conservative projection of procedures peformed by the total membership can be achieved by multiplying by three the procedures done by the 24% of responding members. This yields a value of more than 110,000 laparoscopic procedures performed in 1988. This conservative estimate of gynecologic procedures does not include those performed by physicians who were not members of the Association or by resident physicians in training.

In spite of the widespread acceptance of laparoscopic surgery, the efficacy and safety of such procedures have not been established. Therefore, my assignment was to ascertain the safety and efficacy of laparoscopic surgery in the management of infertility and endometriosis.

It was readily apparent that a clearly defined end point for success or failure could be established for treatment of infertility; the patient either was or was not able to become pregnant after the treatment. For endometriosis success also might be measured by relief of pain and other symptomatic conditions too difficult to assess. For this reason, the success of treatment for endometriosis was also defined in terms of pregnancy outcome. Again, the patient either was or was not able to become pregnant as a result of the treatment.

With clearly defined outcome variables established, laparoscopic surgery for the treatment of infertility and endometriosis could be compared with laparotomy for the correction of these disorders; safety of the two sur-

6/6/35918

gical approaches could also be compared. Infertility and endometriosis that could be treated by laparotomy and laparoscopic methods alone were then arbitrarily outlined as listed below.

Laparoscopic treatment of infertility and endometriosis

I. Infertility
   A. Tubal injury
      1. Iatrogenic
      2. Inflammation
   B. Ovum retrieval
   C. Unexplained infertility

II. Endometriosis
   A. Endometriosis
   B. Endometriomas

The surgical treatment of tubal injury was divided into reversal of previous tubal sterilization (iatrogenic) and injury caused by an inflammatory process. Reversal of tubal sterilization of laparoscopic technique is not actually an established procedure; therefore, this category could not be compared with laparotomy methods. It is acknowledged, however, that a laparoscopic view of a previous tubal sterilization before a definitive laparotomy may prevent an unnecessary laparotomy if the tube cannot be repaired.

Laparoscopic ovum retrieval for in vitro fertilization and other related techniques has been replaced almost entirely by sonographically directed aspiration and is included only for historic purposes. For unexplained infertility it was impossible to obtain comparative data for laparotomy versus laparoscopy; no specific studies could be found that supported this recommendation in spite of the fact that such a recommendation is made in three standard textbooks of endocrinology. Furthermore, no articles since 1975 could be found in which the authors recommended laparotomy for cases of unexplained infertility. Therefore, data were available only to compare pregnancy outcomes for tubal injury.

Pregnancy outcomes for the surgical treatment of endometriosis have been reported for both laparoscopic and laparotomy methods. The specific category of endometriomas is a hotly controversial area with respect to correction by laparotomy versus laparoscopy. Most treatment outcomes for this indication were reported in terms of successful treatment and rates of recurrence, but comparative studies of specific pregnancy outcomes as a result of laparoscopic versus laparotomy techniques were not identified by this reviewer.

For all the reasons listed above, this review will be devoted to a comparison of the efficacy and safety of laparoscopic versus laparotomy techniques to correct infertility caused by tubal injury and endometriosis.

Table I. Quality of evidence

I	Evidence obtained from at least one properly designed randomized controlled trial.
II-1	Evidence obtained from well-designed controlled trials without randomization.
II-2	Evidence obtained from well-designed cohort or case-control analytic studies, preferably from more than one center or research group.
II-3	Evidence obtained from multiple time series with or without the intervention. Dramatic results in uncontrolled experiments (such as the results of the introduction of penicillin treatment in the 1940s) could also be regarded as this type of evidence.
III	Opinions of respected authorities, based on clinical experience, descriptive studies, or reports of expert committees.

Source: United States Preventive Services Task Force.

Table II. Strength of recommendations

A	There is good evidence to support the recommendation that operative laparoscopy be used for this indication.
B	There is fair evidence to support the recommendation that operative laparoscopy be used for this indication.
C	There is inadequate evidence regarding the use of operative laparoscopy, for this indication, but recommendations may be made on other grounds.
D	There is fair evidence to support the recommendation that operative laparoscopy not be used for this indication.
E	There is good evidence to support the recommendation that operative laparoscopy not be used for this indication.

Source: United States Preventive Services Task Force.

Material and methods

A systematic search of all publications relating to the surgical treatment of infertility resulting from tubal injury and endometriosis was conducted with Medline. Only articles published in English after 1975 were considered. Before 1975 microsurgical procedures were not commonly used.

Final outcome variables for tubal injury were tubal patency, pregnancy, viable pregnancy, ectopic pregnancy, and abortion. Pregnancy alone was chosen as the single outcome variable for treatment of endometriosis. Any complication reported was duly noted. No article was included that did not include information that all other causes of infertility had been excluded. It must be noted that there was *no* standard or uniform use of perioperative antibiotics, steroids, hydrotubation, or assessment of tubal patency. Finally, follow-up intervals varied from article to article and even within

groups of patients reported in the same study. Not all reports included life-table analyses of pregnancy outcomes after treatments.

Articles chosen for analysis were separated into these related to tubal injury and endometriosis. Once in these categories, the articles were subdivided into techniques using laparotomy and laparoscopy.

Each article in each category and subcategory was classified according to the rating scale (Table I) reported by the United States Preventive Services Task Force,[2] which was modified from the original methods developed by the Canadian Task Force on the Periodic Health Examination. This rating scale gives greater credence to studies that are subject to less bias, such as randomized controlled studies, and less credence to case reports and expert opinions.

The efficacy and safety of each surgical technique was assessed based on the type of study (Table I), and the existing evidence was considered for each article or group of similar articles. A recommendation was then made on the basis of the United States Preventive Services Task Force scale listed in Table II. If results supporting the safety and effectiveness of laparoscopic procedures were reported in well-designed studies (classes A and B), the technique was recommended for the treatment of infertility resulting from tubal injury or endometriosis. When evidence was inadequate with respect to quality or quantity (class C) no recommendation could be made. If there was either fair or good evidence that laparoscopic surgery was not safe or effective (classes D and E), the procedures were not recommended.

Statistical analysis was performed on a computer program developed by Dr. J. David Erickson of the Birth Defects and Genetic Diseases Branch, Centers for Disease Control, Atlanta, Georgia. Chi-square analysis with Yates' correction was used in all analyses. A difference was considered to be significant if the p value was <0.05.

policy resulted in a merciful narrowing of the possible topics to be considered. When only comparable United States Preventive Services Task Force studies were considered, the choice of papers available for review was further narrowed. For example, listed in Table III are the results of four similar studies[3-6] devoted to the laparoscopic correction of peritubular and periovarian adhesions. It must be noted that in the reports by Reich[3] and Fayez[6] results of their salpingoovariolysis procedures were extracted from more extensive reports of the role of operative laparoscopy in cases of tubal injury. The two reports by Gomel[4, 5] were included because the 1989 review article included an update of the results previously reported in the 1983 report. The data from these four reports were combined because in each study results were reported for treatment of cases of similar severity. In the Reich[3] and Gomel[4, 5] reports the surgery was done because ovum retrieval was judged to have been impossible. In the Fayez[6] report the surgical results were separated into salpingolysis, ovariolysis, and salpingoovariolysis. Only results for salpingoovariolysis were listed in Table III. Reich[3] classified

disease severity with the Hulka[7] classification; Gomel[8] used his own classification. Unfortunately, none of the authors used the same operative techniques and perioperative adjuvants.

In spite of the difficulties listed for this category of laparoscopic salpingoovariolysis, the outcome variables were similar enough to compare results among the individual studies ($p < 0.05$) and to compare all these studies with results obtained by laparotomy (Table IV). All of these reports were United States Preventive Services Task Force class III descriptive studies without controls.

There were two transient brachial palsies reported.[3] Unfortunately, it was impossible to ascertain whether these complications occurred in these patients or in other classes of patients also presented in that report.

Listed in Table IV are the results obtained in four descriptive uncontrolled studies (United States Preventive Services Task Force class III)[3, 7, 9, 10] of salpingoovariolysis performed by laparotomy. Once again, dissimilar classification systems were used to classify the severity of disease, and different surgical techniques were used. These studies were chosen for comparison, however, because they were all class III studies with outcome variables similar to those listed in Table III.

There were no differences in significance noted between the individual studies ($p < 0.05$) listed in Table IV. In fact, when the results for salpingoovariolysis by

Outcome				
Ectopic pregnancy		Abortion		
No.	%	No.	%	Comment
0	0	0	0	3 of 9 cases, by laparoscopy; 1 was primary; 5 bilateral.
0	0	0	0	5 primary; 2 previous surgery (1 endometriosis, 1 inflammatory); 10 cases eliminated for valid reasons.
NC		NC		Viable pregnancies not cited but calculated.
1	4.5	1	4.5	6 of 28 patients were excluded for "laparoscopally unrepairable tubes"; CO_2 laser used in this series.
2	10	0	0	Both pregnancies were ectopic.
3/56	5	1/56	2	—

Outcome				
Ectopic pregnancy		Abortion		
No.	%	No.	%	Comment
3	20	0	0	2 of 3 ectopic pregnancies later delivered; the third ectopic pregnancy had a repeat ectopic pregnancy. 5 of 8 viable pregnancies came after second-look laparoscopy.
5	8	1	2	No viable pregnancies as disease worsened as classified by Hulka criteria.
8/76	10	1/76	1	—

laparoscopy were compared with those by laparotomy (Table V), there still were no significant differences noted in pregnancies, viable pregnancies, ectopic pregnancies, and abortions ($p < 0.05$). Ectopic pregnancies did occur with greater frequency after laparoscopic procedures, however. There were no reported complications in the laparotomy series; therefore, it was impossible to compare the two approaches with respect to safety.

The quality of evidence used to compare salpingoovariolysis by laparoscopy versus laparotomy is class III. There is no evidence (class C) to recommend operative laparoscopy over laparotomy for this indication.

Salpingostomy. A search of the literature since 1975 for reports of the efficacy and safety of salpingostomy performed by laparoscopy and laparotomy resulted in the identification of no randomized controlled studies or even cohort studies. Only uncontrolled series of case reports (Tables VI and VII) were identified. There were five series[3, 6, 11-13] reporting similar outcome variables for laparoscopic surgery (Table VI). There were no reported complications, and the differences between these series were not significant ($p < 0.05$).

With respect to salpingostomy performed by laparotomy (Table VII), only two studies[3, 7] were identified in which outcome variables could be compared with results obtained by laparoscopy. The study by Reich[3] was considered closely before it was included because five of the eight viable pregnancies occurred after a second-look laparoscopy. In spite of reports by DeCherney and Mezer[14] that second-look procedures may improve pregnancy rates and decrease ectopic pregnancies, Tulandi et al.[15] refute this for terminal salpingostomies and salpingoovariolysis. Their study was a well-designed, randomized study in which results for 1 year were analyzed. Therefore, the basis of the results of Tulandi et al.,[15] the series by Reich[3] was included in the results summarized in Table VII.

There were better outcomes in the series reported by Reich[3]; however, because of the second-look approach and small numbers, results were not compared between the two series. The results from both studies were averaged, however, and compared with the results obtained by laparoscopy (Table VIII). There were no significant ($p < 0.05$) differences noted between laparoscopy and laparotomy approaches for salpingostomy, and there were no reported complications in any of the studies.

The quality of evidence for salpingostomy either by laparotomy or laparoscopy is Class III. There is insufficient evidence (class C) to recommend one technique over the other.

Endometriosis. The difficulty in comparing results obtained in the surgical management of endometriosis

is best illustrated by an inspection of the three studies listed in Table IX. The first, by Garcia and David,[16] was a retrospective cohort study that contained a control group of patients who did not undergo laparotomy for surgical correction of their mild disease. Unfortunately, the classification of severity was based on the 1973 Acosta classification, which is no longer widely used. In addition, there were too few patients with mild disease treated to make this a truly meaningful report. It is included here only because 17 patients with mild disease were *not* treated and 11 (65%) became pregnant. This was, in fact, the only report identified since 1975 in which there was a control series of patients. Schenken and Malinak[19] reported similar success without treatment for minimal and mild endometriosis. Again, it is unfortunate that a more current classification was not used in the study by Garcia and David.[16]

The series by Fayez et al.[17] was matched with that by Damewood and Rock[18] to illustrate their differences and to describe why they cannot be compared. Although both groups of authors used the revised American Fertility Society (1985) Classification for Endometriosis, the varying uses of hormonal therapy made the two series impossible to compare. This, unfortunately, was true for most descriptive unrandomized and uncontrolled series that were reviewed.

The difficulty in comparing results reported in our literature is further substantiated in the Fayez et al. (Table IX) study,[17] in which excisional biopsy alone or in combination with danazol resulted in a better preg-

Classification	*Comment*
Modified Acosta (1973)	Control that had no surgery (mild disease).
Revised American Fertility Society (1985)	a-b = $p < 0.001$ a-c = $p < 0.001$ b-c = NS
Revised American Fertility Society (1985)	"Six months of danazol therapy had been utilized for the six months before conservative surgery or postoperatively for six months in 14 of the patients."

Classification	*Comment*
American Fertility Society (1979)	a + b − c + d = $p \leq 0.05$. Exact surgical technique not described.
American Fertility Society (1979)	a − b − c − d = NS

nancy outcome for treatment of minimal (stage I) and mild (stage II) endometriosis than did danazol alone. Unfortunately, both excellent results were no better than the control results noted in the Garcia and David (1977) study.[16]

I was able to locate two retrospective cohort studies[20, 21] in which the same classification system was used to stage endometriosis and in which both studies reported life-table analyses of successful pregnancies. The results of this comparison are listed in Table X. Both reports also were classified as United States Preventive Services Task Force class II-3 studies. Unfortunately, in the report of Rock et al.[20] the surgical techniques were not described in detail. However, the surgical approach was by laparotomy; therefore, this series was compared to the Nezhat et al.[21] study in which laser and laparoscopy were used.

In spite of the difficulties noted for a comparison of reports of Rock et al.,[20] and Nezhat et al.,[21] they both were judged to be United States Preventive Services Task Force class II-3 studies and both authors used the same classification system (American Fertility Society Classification 1979). There were no reported complications in either series, and there were no significant differences in outcome per class of endometriosis between the two series (Table XI). Thus the quality of evidence is class II-3, but there is insufficient evidence (class C) to recommend the use of laparoscopy over laparotomy. It must be noted in all fairness, however, that Nezhat et al.[21] point out that their success rate was not significantly different from class to class. On the basis of equal treatment results in mild to severe disease, Nezhat et al. claimed that, "Indeed, if results similar to ours are obtained by other reproductive endoscopic surgeons, the obituary of laparotomy as written by DeCherney soon will be published."[21] Based on the meager comparative data available and the United States Preventive Services Task Force classification and recommendation guidelines, this claim appears to be premature.

Comment

A systematic review of the gynecologic literature back to 1975 concerning the efficacy and safety of laparoscopy versus laparotomy for the correction of infertility resulting from tubal injury and endometriosis was conducted. The majority of published papers were primarily a list of expanded case reports (United States Preventive Services Task Force class III) of limited scientific merit. Even worse was the failure of the authors to use the same classification systems for grading the severity of disease they were treating. Worse still was the failure of investigators to use the same, or even similar, perioperative adjuvants, such as antibiotics, systemic or topical steroids, hydrotubations, and various preparations claimed to retard adhesion formation. Standard durations of follow-ups were not used in most studies, and life-table analyses were reported in only a minority of the reports.

My final dispassionate conclusion is that there is insufficient evidence to recommend laparoscopy over laparotomy for the correction of infertility resulting from tubal injury or endometriosis. This conclusion was based on the review of poorly scientifically designed and executed studies, which were all that were available. Also, no conclusions reached were based on economic considerations. Certainly there can be no question that laparoscopic surgery results in a significant reduction in hospital costs compared with laparotomy. Levine[22]

Table XI. Endometriosis outcomes with the American Fertility Society 1979 classification

	Table X				*Significance*		
	Laparotomy (macrosurgery) (Rock 1981)		*Laparoscopy (laser) (Nezhat et al., 1989)*				
	No.	*%*	*No.*	*%*	*χ^2 with Yates' correction*	*Odds ratio*	*p Value*
Mild	28/45	62	28/39	72	0.48	1.54	0.48
Moderate	48/88	55	60/86	70	3.65	1.92	0.055
Severe	33/66	50	45/67	67	3.36	2.04	0.066
Extensive	6/15	40	35/51	69	2.91	3.28	0.087

reported a 49% reduction in overall hospital costs in three categories of patients. His first category included patients undergoing salpingoovariolysis. Equally important is a consideration of recovery time associated with laparoscopy versus laparotomy. Azziz et al. reported convincing evidence that "even the most radical endoscopic procedures required considerably less recuperation time when compared with laparotomies."[23] They also noted, however, that in extensive pelvic procedures, recovery time was prolonged even if the surgery was done through a laparoscope.

What should be done? Certainly, well-designed and well-executed prospective studies *with controls* are essential. The time is long past to continue descriptive studies. The cry that such studies are impractical, unethical, or cannot be accomplished is simply unjustified. In fact, the opposite is true. Today the indications for laparoscopic surgery *almost* approach the technical developments of the equipment. Therefore prospective control randomized studies can be designed. Furthermore, specific outcome variables can be defined, and specific perioperative adjunctive therapy can be specified. Certainly time-life analyses can be made. Modern billing and collections sytems make it a simple matter to compare, prospectively, the costs of newer techniques of laparoscopic surgery with those of conventional laparotomy and with newer techniques, such as minilaparotomy. In fact such studies do not have to be sponsored by the National Institutes of Health or the Federal Drug Administration. These studies can and should be sponsored by the American Gynecological and Obstetrical Society or the American Fertility Society, if for no other reason than that the studies can be completed in appreciably less time and for much less money. For example, in his 1979 book *The Politics of Contraception,* Carl Djerassi estimated that the perfect male contraceptive "would require 12-20 years and at least $15 million before such an agent would be available to the U.S. consumer."[24] Thus our professional societies should sponsor this clinical research and mandate that the newer types of laparoscopic surgery be compared with newer nonlaparoscopic procedures such as minilaparotomy.

In closing, I have not identified objective evidence that "the obituary of laparotomy for pelvic reconstructive surgery has been written," as DeCherney suggested in his thoughtful editorial, "The leader of the band is tired . . .."[25] Certainly there can be no advantage in performing a 8-hour laparoscopic marathon to ablate endometriosis that might just as well have been completed 5 hours earlier through a minilaparotomy incision at the same cost in dollars and postoperative recovery time and with better results and fewer complications. Indeed, maybe the leader of the band is tired for a good reason.

The need for technology assessment in the reproductive sciences

Paul G. McDonough, MD
Augusta, Georgia

OBJECTIVE: The problem confronting medicine is the rapid diffusion of technology without prior broad-based critical peer review. Laser therapy is an archetype of this problem.
STUDY DESIGN: Guidelines are needed to identify those medical and surgical procedures that are experimental and those that are truly "state-of-the-art" technology. To be cogent these guidelines must cover nonbiomedical issues and include comparisons with alternative modes of therapy.
RESULTS: Steps must be taken to augment the number of individuals in our discipline who can provide leadership in technology assessment and health services research. Joint ventures between professional societies and third-party payers are a logical approach to developing and funding technology assessment programs.
CONCLUSIONS: These steps should help ensure that clinical decision analysis and operations research develop as a bona fide scientific discipline within the reproductive sciences. Scientific resources developed in this way should help to improve health care by eliminating ineffective procedures and retaining the technologies that are most effective and economic. (AM J OBSTET GYNECOL 1992;166:1082-90.)

Key words: Laser, technology assessment, clinical decision analysis

Problem

It is not possible in the time allotted to completely cover the subject of laser therapy. An analysis of laser as a therapeutic modality is appropriately the charge of an ongoing task force of diverse experts permanently commissioned for the task. Without continued reassessment, singular assessments of technology may be unfair to important evolving technologies and hazardous to the progress of science. The laser is an interesting example of a technologic frontier in which, because of its intrinsic novelty, the creation of the instrument itself has provided much of the market impetus for development. The majority of analyses of laser therapy in gynecology indicate that laser therapy is no more effective than alternative therapeutic modalities and is clearly more expensive.[1] Laser therapy has a well-established role and precise indications in ophthalmologic surgery and, to a lesser degree, in otorhinolaryngology.[2, 3] In ophthalmology certain procedures cannot be performed without a laser. Someday the surgical laser may assume such a singular position in gynecology, but currently it is struggling to compete on a cost-effective basis with electrosurgical and even radiosurgical techniques.

From the Reproductive Endocrine Section, Department of Obstetrics and Gynecology, Medical College of Georgia.
Panel Presentation, presented at the Tenth Annual Meeting of the American Gynecological and Obstetrical Society, Carlsbad, California, September 5-7, 1991.

More important are the underlying issues spawned by these discussions that transcend any single technology, of which laser, because of its obvious marketability, is a fitting archetype. In recent years technical developments in the biomedical sciences and their growing applications to the diagnosis and treatment of disease have been exponential. The speed of these technologic developments and their rapid dissemination, especially to the public sector, have been largely responsible for the conundrum that we are tactfully trying to address here today: the diffusion of technology without prior broad-based critical peer review.

Increasing competition, demands for financial performance, and the need for a market edge tempt even the most conscientious health practitioners to select highly technologic modes of diagnosis and therapy that are more legitimate in the eyes of the public than in the eyes of scientific peers. The risk inherent in this type of marketplace peer review is that it will become the major determinant of practice patterns and even affect the direction of medical science. The end result will be treatments and procedures that are of uncertain value because they lack the type of solid primary data necessary for scientific validity. Procedurally oriented treatments and their indications are especially constituted to short-circuit peer review and sideslip into our therapeutic armamentarium. Such treatments or procedures receive public acceptance, become medical fashion, and are difficult to countermand. Some type of critical premarket analysis is essential for all technology; it is especially important for laser therapy,

which seems to provide an aura of high technology with emotional appeal to surgeon, patient, and health care administrator that is difficult to resist. Guidelines in this and similar areas of medical innovation are important for the public good and are sure to come from other directions if professional societies fail to decisively lead all phases of technology assessment.

Need

Technology in the broadest sense includes drugs, devices, and procedures. Approval of a medical device such as the laser by the Food and Drug Administration serves only to acknowledge officially that the device can do what the manufacturer claims. The Food and Drug Administration does not regulate the procedures for which a medical device can be used, but does provide approval to manufacturers for a specific procedure for which a device can be marketed. Appropriate use is the function of the health practitioner. The analysis of appropriate use is the domain of health care technology assessment. The primary prerequisite for appropriate-use analysis is the development of guidelines to identify which medical treatments or surgical procedures are clearly experimental as compared with those that are state-of-the-art technology. To develop into such guidelines, a single, uniform instrument for the initial evaluation of new technology, continued analysis of existing practices and procedures is essential. In the past, technology assessment principally emphasized the efficacy and safety of a medical or surgical intervention. This focus derived from the assessors who were physicians, scientists or, rarely, biostatisticians involved in patient care or product development. Technology assessment is now a comprehensive form of evaluation and policy research that evaluates a much broader spectrum of consequences of health care interventions.[4, 5] Analyses of these diverse downstream issues require the skills of individuals trained in such disciplines as economics, sociology, epidemiology, operations research, and psychometry. The shortage of such expertise among us is a deficit that will need to be corrected. For example, the cost-benefit issue is especially relevant to laser therapy, in which large financial outlays and training commitments are necessary. These costs and their benefits need careful quantitation and comparison with alternative therapies by a member of the health care team with special expertise in that area. It must be carefully assessed whether the net surgical outcome for the patient, including quality of life, is different with the laser than with these alternative therapies. The relative efficacy of laser to nonlaser therapeutic modalities and the laser's effect on the healing process in comparable human structures have been studied in only a small number of juxtaposed experiments. The opportunity for an ipsilateral control side and a parallel experiment is rare in human beings. Unilateral blepharoplasty by cold knife and contralateral blepharoplasty by laser do not reveal differences in primary healing.[6] Similar comparisons with similar results have been described for bilateral vocal cord polyps.

In terms of safety the laser might be considered to be more dangerous than scalpel or electrocautery. On the other hand, the laser does facilitate the dissection and ablation of disseminated types of endometriosis by providing enhanced precision, selective tissue interaction, and occasionally improved access to surgical sites via the endoscope. The evaluation of all these distinct aspects of health care interventions, including patient preferences, need for physician education, and psychologic overtones of high technology are now subsumed under the grand rubric of technology assessment or operations research. This new type of evaluation is more complex but potentially more useful than single evaluations of efficacy and safety. If inappropriate treatments could be eliminated through this type of broad critical analysis it would protect patients from ineffective treatments, elevate the standards of clinical decision-making, and perhaps result in the savings of billions of health care dollars each year.

Some of us may be concerned that critical technology assessment will erode our ability to practice as we deem best, create too many regulatory hoops, and limit innovation. Similarly, medical researchers, pharmaceutical manufacturers, and producers of medical devices fear that technology assessment will inhibit the development and diffusion of new forms of technology. These fears may be justified, but even without our leadership the new technology assessment is here to stay and will probably have a large impact on medical practice in this decade. A large number of diverse organizations have active programs in technology assessment and cost-effectiveness analysis. Along with the American Medical Association these include the National Blue Cross/Blue Shield Association, Emergency Care Research Institute, American College of Physicians (Clinical Efficacy Assessment Program), United States Public Health Service's Agency for Health Care Policy and Research, and Health Insurance Association of America. Recently Rockwell International Corporation, concerned with employee health costs, developed a large in-house staff to assess health care practices and limit health insurance coverage.[7] Similar cost-containment efforts by third-party payers with only select professional input may have a ricochet effect, resulting in the abandonment of effective technologies and the retention of ineffective ones unless an adequate and dynamic assessment process involving all members of the health care delivery team is developed.

Recommendations

There is a need for operations research and technology assessment in which obstetricians and gynecol-

ogists play an active and, preferably, a leadership role. Within the framework of our specialty we need to stimulate a public dialogue that will help us develop a systematic and uniform approach to technology assessment. The American College of Obstetricians and Gynecologists has already begun to provide valuable input to the Agency for Health Care Policy and Research. To improve our ability to set priorities and evaluate the technologies in our discipline, certain issues must be addressed: intellectual resources, location, funding, and research.

Intellectual resources. Obstetricians and gynecologists who have training in quantitative methods are in short supply. There are few individuals in our specialty who possess the necessary consummate skills, critical faculties, and specific interest in technology assessment. A few departments of obstetrics and gynecology have wisely recruited and retained singular faculty with these talents. To date it has been perceived as an important problem but has not received educational or training emphasis. The need to develop *intellectual resources* within our discipline who can provide leadership in this area is self-evident, but the strategies are less apparent. It is not easy because it requires the development of physicians who have skills outside the ordinary idiom of obstetrics and gynecology. These cross-skills should extend to sociology, economics, epidemiology, public health, psychology, statistics, and other disciplines. Unique opportunities exist for physician scholars who have expertise in these multidisciplinary skills related to health services research and technology assessment. The development of a handful of such dexterous individuals would probably cover our leadership needs for the next decade.

Currently there are a limited number of training grants available from the Agency for Health Care Policy and Research, National Institute of Mental Health, National Institute of Aging, and Departments of Defense and Veterans Affairs. The 1990s will surely see a more expansionary posture with respect to health services research and training. The availability of training grants and the development of role models in technology assessment are essential to the development of such intellectual resources in our discipline. Perhaps a competitive award to fund individuals for careers as physician-scientists could be used for this purpose. Through their emphasis on prevention and screening, established pediatricians have already begun to galvanize new pediatricians in the direction of health care planning and assessment careers. Similar role models are needed from within our discipline. Individuals with talent along these lines should be encouraged to pursue graduate degrees in public health rather than subspecialization. Residents and fellows in our training programs should receive a broader education in all aspects of clinical decision-making, with a greater emphasis on epidemiology and biostatistics. The inability of our trainees to weigh competing claims for different forms of therapeutic interventions is a major contributing factor to the hypertrophy of technology and the atrophy of critical judgment in our discipline.

Location of activity. Government, third-party payers, insurers, and professional societies are not the sole repositories of health care technology assessment. Assessment activities and research also take place in medical schools, schools of public health, policy centers, and departments of economics, business, sociology, and political science. A directory compiled by the Association for Health Services Research (1982) lists 37 such centers that are based in or are affiliated with academic institutions.[8] Their primary, although not necessarily exclusive, mission is the conduct of health services and policy research. It would seem both appropriate and practical that the location for an interdisciplinary task such as technology assessment should be from within the professional society whose members are primarily engaged in the use of the technology. Professional societies are in a unique position to learn from experience, a critical factor in technology assessment. Societies are also better able to suggest modifications in technology and develop an orderly system of priority evaluation. In this way operations research and clinical decision analysis could develop as a bona fide scientific discipline within the reproductive sciences. It would elevate clinical decision-making from an art to a science, help to attenuate observer bias, and be no less a scholarly pursuit than other forms of basic science investigation. Within a professional society all this might come under the broad umbrella of health services assessment and could include liability issues related to the use of these technologies. A health services research and appraisal program within a professional society would also foster the development of a plan to identify the type of data to be collected and a system for performing this task. A clearinghouse to gather this type of information and make it readily accessible to health care providers and researchers would be invaluable. Society-based activities would allow the optimal performance of many of these activities.

Funding. Undertaking an assessment of technology and other utilization-management issues is particularly expensive. In Canada industry has formed a partnership with government in assessing technology through the Medical Research Council/Industry joint program to fund technology-based research. Perhaps industry and third-party payers would be willing to enter an agreement with a single professional society to fund technology assessment and health services research in obstetrics and gynecology. Industry might be willing to work with the society to control costs and to develop a

better understanding of the scope, limitations, and indications for the technology under analysis. A system that capitalizes on the strengths and resources of a free-market economy and a private-public organization would be most appropriate and less susceptible to political meddling.

The American College of Physicians has been involved with health care technology assessment since 1981 through its Clinical Efficacy Assessment Program. The program initially was funded by a 3-year grant from the Hartford Foundation, but is now fully funded by the American College of Physicians. This project evaluates medical tests, procedures, and therapeutic interventions within the purview of internal medicine and its certified subspecialties. Blue Cross/Blue Shield supported an assessment of diagnostic testing that was performed jointly with the College. Reimbursement for outmoded and useless procedures was stopped and resulted in a significant reduction in health care costs. Blue Cross/Blue Shield is now spending approximately $60 million to fund a randomized trial to evaluate autologous bone marrow transplantation in patients with breast cancer. A joint program has been developed by the American College of Cardiology and the American Heart Association to asssess the role of invasive versus noninvasive procedures in the diagnosis and management of cardiovascular disease.[9] Currently the Health Insurers of America are supporting a large study in collaboration with the American Urological Society to assess alternative therapies for benign prostatic hypertrophy. The current challenge for obstetrics and gynecology is how to join forces with other organizations for funding and effective decision-making. If professional societies hesitate to be involved, the most likely scenario in the United States is that all assessment activities will be coordinated by the Agency for Health Care Policy and Research, with professional societies functioning as resources in a consultative capacity.

Research. Useful methods do exist for assessing medical technologies, but they need improvement. A major issue in health services research is whether experimental control is a prerequisite for the establishment of causal relationships. Methods other than randomized controlled trials need to be investigated to define their role in technology assessment.[10] Research is especially needed on methods of economic and psychometric evaluation. A high technology procedure is frequently selected for a common diagnostic problem like headache because patient and physician alike cannot deal with the psychologic ramifications of uncertainty. Methods are urgently needed to quantitate the role of psychologic factors in clinical decision-making.

Beyond the reasearch problems of special methods there is the ancient problem of assembling information from a variety of sources and integrating the results. Biology and numbers need to be integrated in plausible and creative ways. Data pooling as a mechanism to improve the quality and timeliness of evaluations of diagnostic technology needs to be explored in obstetrics and gynecology. Greater effort and resources are needed to obtain solid primary data about medical procedures in use. As with laser therapy, it can be seen repeatedly that the obstacle to evaluation is the lack of randomized, controlled studies that are necessary for cogent assessment. Lack of information is a uniformly significant problem. A final major challenge within our own profession is to expunge those stereotypically attitudes that insist that clinical decision-making is beyond critical analysis.

Currently there is a variety of funding opportunities available on a competitive basis through the Agency for Health Care Policy and Research for the performance of technology assessment. This 2-year-old agency received $90 million in appropriations for technology research during 1991. This represents an increase of $41,567,000 over fiscal year 1990. Information concerning this funding source needs to be more widely promulgated and even rhapsodized within our discipline. This funding is largely available through the Medical Treatment Effectiveness Program, which has received an appropriation of $68,500,000 for fiscal year 1991. This area is primarily designed to evaluate the effects of alternate treatments on the outcome realized by the patient. Research in this area is receiving increasing emphasis because of concerns for health care costs and quality. A greater proportion of monies flowing to departments of obstetrics and gynecology for technology assessment would increase the general awareness of these important issues within our discipline.

The development and pervasive diffusion of technology for minimally invasive procedures, in part catalyzed by laser therapy, will compel us to address all of these issues over and over again in the next decade. The emerging technology and the increasing similarity of instrumentation between the operative endoscopist, catherologist, and interventional radiologist should be a stimulus for cross-fertilization.[11] Cross-talking and formalized interaction between all of these disciplines would help to avoid duplication and is essential for a more uniform evaluation of new and existing technologies.[12] Our assessment capability should also be indirectly enhanced by new legislation (Medical Devices Act of 1990, Pub L No. 101-629) effective November 28, 1991, mandating a review and reporting program for any malfunction of a medical device. This program covers all regulated medical devices approved through the Food and Drug Administration's Center for Medical Devices and Radiobiological Health. This mandatory reporting requirement transfers the burden of

monitoring and reporting medical device malfunction from the manufacturer to the institutions where the medical devices, such as lasers, are being used. Sharing this information across disciplines should avert the repetition of technology-related error and more accurately portray the frequency of laser incidents.

Surgery of the future

Because of its promise, laser technology has at times been clouded by hyperbole, illusion, and myths that have grown like Jack's beanstalk. The realistic future of laser surgery rests on a fuller appreciation of the basic physical and chemical mechanisms by which light interacts with organs and organelles. These insights will establish when it is right to use the laser and when it is not. Recognizing when a scalpel or a $5000 electrocautery knife can be more appropriate and less risky than a $100,000 laser device is pivotal to the continued success of laser technology in medicine.

Apart from laser biochemistry, a second reason that will ensure the survival of endoscopy surgery is the development of technology that will enable computers to generate and manipulate three-dimensional video images. This is not far in the future. A computer monitor will generate a bright, three-dimensional image of the patient's pelvis from data it receives from a magnetic imaging device. Using the three-dimensional image to reconstruct the original image on a television monitor can help us to appreciate the shape of normal anatomic structures as well as the dimensions of disease. Although these techniques require a complex combination of optical, mechanical, laser, and computer technology, the objectives are obtainable. These live computer-manipulatable, three-dimensional images should be available within 5 to 10 years. Surgeons unable to function with current two-dimensional imaging will be back to the more comfortable spatial dimensions of the real world. At the same time advances are continuing in laser technology on many other fronts. The excimer laser uses instantaneous bursts of light and does not leave a burnt, charcoal-like surface.[13] There are many new techniques for trapping and manipulating atoms, dielectronic particles, and even organisms with light forces.[14]

Only hermetically controlled trials carefully carried out over the next few years will clearly codify and define the true potential of the laser. In the meantime it is incumbent on all of us to assess technical "advancements" in a methodic, scientific, and ethical manner. It is important to keep a balance between clinical needs, technical capabilities, and costs. More careful evaluation of clinical efficacy is especially needed as additional high-cost diagnostic measures and therapeutic interventions are proposed.

In the last analysis, whether surgery occurs at the level of the patient, organ, or cell, lasers offer physicians and researchers an unprecedented and precise set of optical tools. Only time and good clinical studies will tell whether these tools are used most effectively and appropriately for the patient's well-being.

Discussion

Dr. Alan H. DeCherney, New Haven, Connecticut (Fellow). At the Twenty-seventh Annual Meeting of the American Gynecological and Obstetrical Society in the year 2017, three distinguished members were out playing a sedentary game of golf at the Homestead: Drs. McDonenuff, Rymes, and Cant. As luck would have it, lightning struck and all three perished immediately. Hustled off in sleek white limousines, they were cleaned up, dressed in white caftans, and informed that tomorrow would be Judgment Day. All three slept poorly. McDonenuff ruminated over every precise issue of his life, thinking as to what would be the significant event. Rymes tossed and turned. His head filled with an end-

less stream of numbers and formulas, none of them making any sense. Yet he knew that somewhere in this conglomeration would be his comeuppance. Cant probably slept the best, although frequently there was tumultuous yelling of meaningless aphorisms—things that he had said during his lifetime, none of which he thought he would ever be accountable for because he did not understand then when he said them.

At last, dawn arrived. They were ushered in single file before the judge, Ken Righteous, who stated that the custom here was to look back on the date that you died and throughout the years, find the one day that was significant, and judge from your actions on that day whether time immemorial would be spent in heaven or purgatory. Ironically, the day chosen for this group was the same: September 7, 1991. Judge Righteous said, "You have probably forgotten that day, but that was the day you debated laparoscopic surgery and laser technology. The question here is an easy one, and it is the age-old question of progress versus status quo, liberal versus conservative philosophy." And he stated that judgment in their individual cases would be made based on retrospective wisdom. If their ideas enhanced progress, that would be looked on favorably; however, if their comments on that day were meant to impede progress, that would be weighed against them.

He warned each of them that their arguments must be philosophically sound, because in life that is what counts.

He then turned his attention to Rymes. "Rymes," he said, "you probably remember that in my former life I was a well-known moral philosopher and, just to refresh your memory, a moral philosopher is one who does the right thing based purely on logical evidence. I was quite famous for the quip, 'It is what your grandmother would do.' You have brilliantly described the litany of techniques, dissected this subject thoroughly, and implicated a 'quality of evidence chart,' but, alas, your conclusion was; 'We should not move ahead unless randomized control studies are carried out.' This is an antique argument, and one must ask, 'Why have the dexterous brotherhood never been able to carry out this type of study?' You describe the Vermonter's study that says to demonstrate a 50% higher rate of persistent trophoblast in ectopic pregnancies treated by laparoscopy 2338 subjects would be required. Sarcastically I say, is this practical? Are there not too many variables in surgical studies to really do random controlled studies? Is it not contrived to think that we can study, as you suggested, these surgical procedures with the same scrutiny that we study medication? After all, surgeons are not cognitive procurers of soups and potions.

"Why aren't descriptive studies good enough for complications? Although you've tried to obfuscate the picture with a series of Cartesian arguments, I need not remind you that Descartes, in the search for truth in which all philosophers are employed, believed that a numeric formula providing real truth was unattainable. I think that, although your suggestion for randomized control studies is comprehensive, it is impractical and perhaps illogical. Yet in your defense, Rymes, I offer the following rhyme by the former Poet Laureate of the United States, Howard Nemerov:

> Praise without end the go-ahead zeal
> of whoever it was invented the wheel;
> But never a word for the poor soul's sake
> that thought ahead and invented the brake.

Next, McDonenuff was ushered into the dock. Over the quivering, emaciated Dr. McDonenuff, Judge Righteous stood to his full height, his disheveled red hair like a sunburst and roared "Technology assessment!" Then he sat down.

"McDonenuff," he said, "we have just heard Rymes's procedure assessment paradigm. Your argument is the contrary: a technology assessment paradigm. Once again a logical assumption, but extremely flawed, I am afraid. By your own admission you discuss the improvements made in ophthalmology and otolaryngology with the use of new technology, the laser, to be precise. On that day in 1991 you discussed the failure to prove a 'cost-effective basis' of laser technology when comparing it with an electrosurgical approach. These were good arguments, and I was really excited. You talked about the system being driven by the competitive and business nature of medicine; this was timely, for it was in the late 20th century that medicine became a profession once again after a brief sojourn as a job.

"My heart went out to you in empathy when you discussed the faults with a public-driven rather than a profession-driven system. But, alas, your solution left me disappointed. Regulatory bodies? Just the cost of commissions to study technology assessment would be prohibitive. What would be the chance that industry would be motivated to be a partner in technology assessment?

"You boldly suggested, and also recognized the impracticality and the cost of, the sacred randomized controlled study. You have used Mills's utilitarian argument. Although the premises were logical, the solution was utilitarian but illogical.

"But I was most surprised, McDonenuff, when I recall that fateful day 17 years ago when I discovered that you, yourself, were addicted to technology. Suggesting an empiric approach to animal studies, why not the same for patients? And then you titillated us with the use of three-dimensional images for carrying out surgery.

"Progress mediated by commissions, bureaucrats, and entrepreneurs—a paradox!"

Righteous looked somewhat euphoric as Cant strutted toward the defendant's dock. A man who made the analogy of a laparoscope being just another sword in the belly would provide clear insights into this conundrum. Maybe he would be the one to point out that the day of "show and tell" is over and that the time for honest intradisciplinary professional assessment of the complications and effectiveness of these techniques was at hand. Perhaps Cant, with his more focused mind, could cut through the mass of data provided and suggest even quasi-conclusions and guidelines. But what

we saw that day was a marriage of Humian cynicism and Texas homily. "Nothing works, there are no dramatic results, and we are only cutting hospital stay by 1 day." Righteous said, "At best, using quality of evidence criteria, you are able to concede that some of the studies reached the nirvana of II-3 in the *Book Grimes*. But basically you were inundated with data."

Banging his gavel on the table, Judge Righteous said, "Enough. I have come to profound conclusions and I am ready to pronounce eternal judgment on these three. I have devised a special purgatory for two of them. One is condemned to listen endlessly to the George and Ira Gershwin song "They All Laughed":

> They all laughed at Christopher Columbus when he said the earth was round.
> They all laughed when Edison recorded sound.

The other is condemned to listen endlessly to the Cole Porter tune "I Get A Kick Out Of You":

> My story is much too sad to be told,
> but practically everything leaves me totally cold.
> I get no kick from champagne.
> Pure alcohol doesn't thrill me at all.

And the third, because his arguments were most logical, used the philosophic precept correctly and, most important furthered progress in this important field rather than impeding it by being a naysayer, will go to heaven and for eternity will treat endometriosis in infertile patients with a laparoscope and a laser."

Judge Righteous then exited the chamber humming the final bar of that Gershwin tune, "Ha, Ha, Ha, who's got the last laugh now!"

DR. ROY M. PITKIN, Los Angeles, California. I would like the panel, particularly David and Norman, to give an opinion as to what extent, if any, the indication for an operation is influenced by its cost, cost being defined in the broadest possible sense to include financial costs and risks and inconvenience.

Specifically, a couple of the operations you mentioned, lysis of adhesions and section of the uterosacral ligaments, were not done by laparotomy for the last 40 years but are now being revised and done by laparotomy. If they were not indicated by laparotomy, does the proposition that they can be done with less cost, defined in that broad way, make them a proper indication for laparoscopy?

DR. GANT. Roy, I am glad you asked the question. There is absolutely no doubt that if the endometriosis is mild or minimal disease, stage I or II, you get just as good, if not better, pregnancy results by doing nothing.

DR. MCDONOUGH. Your point, Dr. Pitkin, is an interesting one. Previously discredited macrosurgical procedures (presacral neurectomy, ovarian wedging, etc.) are born again when performed through the endoscope. Apart from some unsubstantiated claims that adhesions are less, etc., there is no logical reason to assume that they have undergone any type of scientific metamorphosis. I take issue with Dr. Grimes on the efficacy of ovarian drilling. There are approximately 12 or 13 publications on the use of this procedure in polycystic ovary syndrome. The outcome looked at in the majority of these publications is the postoperative restoration of steroid levels to normal; comparisons are made with steroid levels in a group of normal ovulating controls. An appropriately matched control group of anovulatory subjects was not used in any of these studies, and ovulation restoration in the treatment group was a therapeutic end point in only a few. As Dr. Pitkin indicated, when analyzed appropriately, a discredited macrooperation (ovarian wedge resection) is no more effective than a similar procedure done endoscopically. We are reinventing the wheel for all of these operation fossils.

DR. GANT. May I add just one other thing? The classic example is that the final step in a negative infertility evaluation must be a laparoscopy. I could find no one who advocated laparotomy for this, and yet I found no one who could report on the incidence of something they found that they could treat that resulted in pregnancy. This number was quoted as 50% in one of the textbooks, but there was no reference.

DR. GRIMES. Let me respond to Paul's point. There is one randomized clinical trial I am aware of from Kuwait that did have three arms. One was ovarian drilling. The other two were medical therapies, and they found comparable rates of ovulation in that one study.

SECRETARY SCOTT. Dr. Pitkin, you mentioned that operations previously discredited and abandoned are now being advocated and performed laparoscopically. What role should be expected of journals, editors, and academic departments in preventing this sort of situation from developing?

DR. PITKIN. I will ask our resident philosopher DeCherney whether that is the classic example of a rhetorical question or begging the question. It is one or the other, but the implications of what you say I would agree with. The peer-review process has to decide, and that means that journals, in particular *reviewers* of journals, have the responsibility to make certain that conclusions are based on the data presented.

Varying studies or varying analyses of published works show that somewhere between 30% and 50% of the time the conclusions stated, usually in the last sentence of the abstract of the paper, are not justified when examined by independent review; this would be an example of that.

DR. MCDONOUGH. One thing I have been impressed with is the ability of metaanalysis to point out the strengths and weaknesses of the literature in the areas we are discussing today. These weaknesses should stimulate a certain amount of soul-searching among all of us concerning standards for scientific publications. Definitive answers to most of the questions we are discussing will not be available until the appropriately designed studies are performed.

DR. CARL LEVINSON, San Francisco, California. Just one comment for each of the speakers. It has been interesting to me to listen to the Russians, all of whom speak English. I think Dr. Grimes unfortunately missed a good many reports dating back to 1973 from the group in Clermont-Ferrand headed by Dr. Bruhat;

many of these studies are truly comparative studies. I recommend that we go back and look at some of those. They are ongoing and they are very, very good.

As far as evaluating laparoscopic surgery for endometriosis, Norman, could we consider those patients who have symptoms and relief of symptoms by surgery and dismissal the same day? It really is quite productive. And Paul, one of the things Alan mentioned was the assessment of surgical skill. When you talk about a technical procedure, technology, and the use of that technology by human beings, how do we assess the use of the technology?

I have been to many centers, and I can tell you there are some people who know how to use the laser and there are many people who do not.

DR. GRIMES: I will respond first. Regarding the publication by Dr. Bruhat, there are a number of his articles in my reference list. Those that were published in French are excluded, as I explained.

DR. GANT. My literature search with Medline was in English and went back to 1975 and because I could not compare so-called modern microsurgery with the macrosurgical techniques before that time.

With respect to the symptoms within endometriosis, I accept the criticism that you are making, but I excluded symptoms and qualified that in my presentation and in the paper because it is most difficult to compare study with study with study. I picked clean end points that I could measure—either the women were pregnant or they were not—as a scientific analysis of these techniques, and I limited them only to whether the pregnancy was successful or not.

I acknowledge that many patients are made symptomatically better. I am also reminded that in drug studies many patients who get the placebo are made symptomatically better as well. And a laparoscopy procedure is a very expensive and dangerous placebo.

DR. MCDONOUGH. This quantitative process (meta-analysis) that we are discussing does not provide an evaluation of surgical technique, but the appropriateness of the procedure, treatment, or intervention. It may be a small consolation to patients to know that their operations, though inappropriate or unnecessary, were performed with great skill. In addition to pooling the quantitative results of many studies, I spoke to quite a few people with the Agency for Health Care Policy and Research, third-party payers, and individuals from private foundations who do technology assessment. Much of the technology assessment done by private foundations is generic in nature, meaning that comparisons with alternative forms of therapies or interventions are not performed. On the other hand, third-party payers and the Agency feel strongly that cogent assessments must include comparisons with other alternative forms of therapy and with no therapy at all.

DR. GANT. Carl, you were emphasizing that the surgeon must be accomplished. Let me assure you I read no paper in which the author did not know how to do what he or she was describing.

DR. KAMRAN S. MOGHISSI, Detroit, Michigan. As usual, the truth appears to be somewhere in between. I think these procedures have merit, but there are also abuses. I have a very difficult time conceiving that we will be doing hysterectomy and other operations that were not mentioned by the panel such as myomectomies through the laparoscope. A myomectomy that is done through a laparoscope probably need not be done.

Often I have seen videos of these so-called myomectomies leaving an enormous crater in the uterus, and these craters are left to heal by themselves. I shudder to think what happens in the subsequent pregnancy. I think there were about a dozen papers in the early 1970s when diagnostic laparoscopy came into use indicating that in patients with unexplained infertility who were subjected to laparoscopy somewhere between 30% and 50% had additional pathologic conditions that were not detected by usual diagnostic techniques. I think those data are the basis of the mention in a number of textbooks that a laparoscopy is mandatory in patients with unexplained infertility.

DR. GANT. In those articles they were limited to mild or minimal endometriosis where the operation either by laparoscopy or by laparotomy achieved the same results as no therapy.

DR. MOGHISSI. Many of these patients have endometriosis, but others have had other lesions such as peritubal adhesions that are not detected by any means except laparoscopy. I think we have to put these in the proper perspective.

One additional comment in support of what I think Paul mentioned: I have looked at the review of the literature comparing laparoscopy with electrocautery. I cannot find evidence that there is difference between cautery and laser with respect to suppression of endometriosis or improvement of fertility.

Now it is quite apparent that it costs about $70,000 to $80,000 to install a laser in any operating room. Cautering costs a few thousand dollars. I think that is another area that needs to be very critically reviewed.

DR. MCDONOUGH. The reason I stressed ophthalmology is that there are certain operations in ophthalmology that cannot be performed without a laser. If you want to traverse normal tissue and affect an area in the retina, you must use a laser. In gynecology laser therapy is easily interchangeable with electrosurgical and even radiosurgical techniques.

DR. GRIMES. I would like to respond to Dr. Moghissi as well. He is correct. There is at least one report in the *Journal of Gynecologic Surgery* describing laparoscopic myomectomy after treatment with gonadotropin-releasing hormone analogues to make the fibroids shrink.

With regard to Dr. DeCherney's earlier comments about sample size, I think that leads naturally into praise for groups such as the Gynecologic Oncology Group, who have mounted randomized clinical trials nationwide that have contributed so much to our information. I think this is clearly needed in the area of laparoscopy as well.

I do not want to be on record as opposing progress

in laparoscopy. What I do oppose, however, is fadcism in surgery. We all recall 15 years ago the epidemic of transsphenoidal hypophysectomy we created in this country that promptly went away once we took a critical look at the data.

Dr. Thomas Kirschbaum, Bronx, New York. You and I feel very much the same with regard to evolution of knowledge.

On the other hand, at the heart of some of Alan's comments is the natural history of the new idea. New ideas enter our field as a result of human ingenuity and the desire to academically advance and to do a better job; soon monetary influences raise their heads. The flood of enthusiasm for new procedures undergoes the bell-shaped curve with respect to time.

Those are strong forces. They are not bad forces, and it seems to me that they gradually play their way out. People make enough money, get tenure, become professors, and establish a position in the world; then their instinctive self-motivated ambition starts to fade.

People come along and make rational judgments 20 to 30 years after the inception of the idea unopposed by enthusiasts and entrepreneurs. The potion satisfies the entrepreneurs, it satisfies those who need academic advancement and in a way it satisfies our gripe about the lack of critical appraisal of new ideas.

Out of that process comes progress, I guess. I think that is Alan's point. Messy as it is, irrational as it is, that is the way we behave around the introduction of new ideas of possible merit to our field.

Dr. McDonough. Tom, you are relying on "natural" selection pressures operating over time to eliminate ineffective, harmless, and harmful treatments. Selection pressures may work over eons in biology so that only the best survive, but one of the principal problems in medicine is that many useless, ineffective, and occasionally harmful procedures are retained. As a patient I would not want to be innocently caught in the slow, gradual evolution of medical innovation.

Dr. Kirschbaum. No. Not all results are good.

Dr. Gant. One example of the result not being good is the Usher regime popularized to treat hyaline membrane disease by administering sodium bicarbonate. To make a baby or any fetus bleed into its head now, all you have to do is make it hyperosmolar. This was done in humans for a long period of time on the basis of an original study that "almost reached statistical significance," $p \leq 0.06$.

Dr. John L. Lewis, Jr., New York, New York. I have a brief comment that is both cynical and optimistic. I think we are going to get the studies that you want to prove efficacy, but they will not necessarily come as quickly from within our group as from outside. Third-party payers now fairly routinely refuse to pay for phase 1 and some phase 2 chemotherapy trials on the basis that they have no proven efficacy. The first time they say they will not pay for surgical procedures before the development of evidence of efficacy, we will begin to get the studies very quickly.

Dr. John Larsen. I have listened with some interest to the projections of regulation and the econometrics; however, I have not heard anyone talk about teaching. When the group puts forward its recommendations, teaching is a point over which this society of scholars, chairmen, and professors might be able to exert some control more readily than they could over expensive, ideally controlled studies or regulation of industry. As you go forward with this, would you consider describing what new techniques the prudent academic department should teach its trainees so they may go out in the community and earn a living?

Dr. Grimes. I think that is a very important point. One of our jobs as academicians is to help define what is worth teaching.

Dr. McDonough: I think we need to put more emphasis on clinical decision analysis and spend more time teaching quantitative techniques to our residents and fellows. This or any other professional society cannot do technologic assessment because it is too expensive. You have to figure out some way to join forces with industry or third-party payers who can support this type of activity. Other societies are adopting that strategy. The American College of Physicians, the American Urological Society, and the American Pediatric Society are becoming copartners with third-party payers for technology assessment. They are starting with well-focused projects that will expand to other broader projects because insurers are motivated to critically evaluate alternative forms of therapy, including the biomedical aspects, for economic reasons. If we do not get into the other nonbiomedical issues we are going to be standing on the sidelines. We cannot remain comatose on this topic; otherwise, technology assessment and this type of operations research will be done exclusively by third-party payers. From their perspective, assessment must be comparative to be relevant and address a broad range of issues, including efficacy, safety, cost, patient preference, liability, and psychologic issues. It is clinical decision-making elevated or reduced, depending on your perspective, to a multidisciplinary science. The fine art of clinical decision-making is in the process of being demystified by the health care analysts.

Dr. Gant. The surgeons are doing this with cholecystectomy, for God's sake. Why can we not do it? We taught them how to use the swords.

Dr. McDonough. But you need money to do technology assessment, and money is in short supply.

The effect of cesarean section on intraventricular hemorrhage in the preterm infant

Garland D. Anderson, MD, Henrietta S. Bada, MD, David C. Shaver, MD, Carol J. Harvey, RNC, MS, Sheldon B. Korones, MD, Seok P. Wong, PhD, Kristopher L. Arheart, MS, and Hubert L. Magill, MD

Memphis, Tennessee

OBJECTIVE: The null hypothesis is that active labor is a more important factor with regard to both timing and progression of periventricular-intraventricular hemorrhage than is route of delivery. Infants delivered by cesarean section after entering the active phase of labor will behave in a manner similar to that of previously studied infants delivered vaginally as to when periventricular-intraventricular hemorrhage occurs and frequency of progression.

STUDY DESIGN: The 106 infants of 85 women delivered by cesarean section were the subjects of this study. Forty-six infants were in the no-labor group, 33 in the latent-phase labor group, and 27 in the active-phase labor group. Head ultrasonographic examinations were performed at delivery, at 1, 6, 12, and 24 hours, and then daily for the first 7 days of life. Continuous variables were compared by one-way analysis of variance among those infants with no hemorrhage or with periventricular-intraventricular hemorrhage. Categoric variables were compared by χ^2 analysis and Fisher's exact test when appropriate. A p value of <0.05 was considered significant.

RESULTS: There was no difference in the frequency of early hemorrhage (≤1 hour of age), late hemorrhage (>1 hour of age), or overall periventricular-intraventricular hemorrhage in the infants not in labor, in latent-phase labor, or in active-phase labor at the time of cesarean section. However, the frequency of grade 3 or 4 hemorrhage and the progression of hemorrhage were significantly higher in the infants whose mothers had an active phase of labor compared with infants whose mothers had no labor or did not progress beyond the latent phase. Infants who had early periventricular-intraventricular hemorrhage (≤1 hour of age) also had a higher frequency of progression of hemorrhage.

CONCLUSIONS: Cesarean section before the active phase of labor does not change the overall frequency of hemorrhage but results in a lower frequency of progression to grade 3 or 4 hemorrhage. We do not feel that these data support performing more cesarean sections for preterm delivery as a method of preventing progression of periventricular-intraventricular hemorrhage in the preterm infant. (Am J Obstet Gynecol 1992;166:1091-101.)

Key words: Periventricular-intraventricular hemorrhage, active-phase labor, time of hemorrhage, cesarean section, progression

The relationship of route of delivery to the pathogenesis of periventricular-intraventricular hemorrhage in the neonate is much less controversial than before. The preponderance of recent studies has shown that the frequency is independent of the mode of delivery.[1-5] A recently published large multicenter study[6] involving 1765 infants with birth weights of ≤1500 gm confirmed these observations. It found that cesarean section did not lower the risk of mortality or periventricular-intraventricular hemorrhage.

However, the time when periventricular-intraventricular hemorrhage occurs may be affected by active labor. A preliminary report from our institution suggested that infants whose mothers experienced the active phase of labor, regardless of the route of delivery, had an increased frequency of periventricular-intraventricular hemorrhage in the first hour of life as compared with the infants of women delivered by cesarean section before active-phase labor.[7] We previously reported that in infants delivered by cesarean section before the active phase of labor periventricular-intraventricular hemorrhage developed in 7.7% at ≤1 hour after delivery compared with 42.9% of infants whose

mothers were in active-phase labor ($p = 0.006$). However, by day 7 of life, the frequency of periventricular-intraventricular hemorrhage in infants delivered by cesarean section before active-phase labor was 38.5%, which was not significantly different from the 52 4% found in the infants whose mothers experienced the active phase of labor.

Interestingly, of the infants who experienced the active phase of labor and had periventricular-intraventricular hemorrhage, 18 of 33 (54.5%) had progression of hemorrhage to grade 3 or 4 compared with 0 of 8 in the no-active-phase labor group. We were impressed with how similar the infants whose mothers had cesarean section after entering the active phase of labor were to the infants delivered vaginally, with regard to both the onset and the progression of hemorrhage. To further examine the role of active-phase labor rather than route of delivery, we decided to study the preterm infants delivered by cesarean section that were part of a continuing study at our institution. Our hypothesis was that infants with periventricular-intraventricular hemorrhage delivered by cesarean section after the active phase of labor would have the same findings with regard to timing and progression of hemorrhage as would previously studied infants that were delivered vaginally. We also expected a higher frequency of early hemorrhage (≤1 hour of age), a similar overall frequency of hemorrhage at 7 days of life, and a higher frequency of progression to grade 3 or 4 hemorrhage in the infants who have cesarean section after active-phase labor compared with infants delivered by cesarean section before active-phase labor. We report a prospective study that includes serial ultrasonographic head scans of the infants, with the initial scan performed in the first few minutes of life, to examine the role of active-phase labor and development of periventricular-intraventricular hemorrhage. This study reports on all the infants delivered by cesarean section in this study.

Material and methods

This study was carried out at the Regional Medical Center, Memphis, after review and approval by the Institutional Review Board of the University of Tennessee, Memphis. Informed consent was obtained from the mother before delivery of the infant. All women,

irrespective of age or parity, admitted to the labor and delivery area from January 1986 to June 1988 with an ultrasonographically estimated fetal weight ≤1750 gm were screened for entry into the study. Medical and obstetric risk factors were recorded. The length of labor, frequency of uterine contractions, length of the active phase of labor, and length of the second stage of labor were recorded. The active phase was arbitrarily considered to begin when the cervix dilated to 4 cm. For women in preterm labor or with the diagnosis of preterm rupture of the membranes, the active phase was considered to start at the last time the cervix was found to be 4 cm dilated before progression into the active phase of labor. When appropriate, women in preterm labor were treated with tocolytic agents.

Antenatal steroids were given at the discretion of the attending physician. Women were allowed to deliver vaginally unless there were obstetric or maternal indications for cesarean section. Outlet forceps were used during vaginal delivery at the discretion of the attending staff. Obstetric management was carried out under the supervision of the maternal-fetal medicine attending staff.

The pediatric team members were present at delivery and were responsible for neonatal resuscitation, stabilization, and assignment of the Apgar scores. As soon as the baby's respiration or ventilation was established, the initial head ultrasonographic scan of the neonate was performed. This procedure was done by experienced personnel assigned to the research project while the neonate's primary caretakers continued with the medical management of the neonate. After stabilization, the infants were transported to the neonatal intensive care unit for further assessment and treatment.

Findings of periventricular-intraventricular hemorrhage were graded according to the criteria of Papile et al.[8] Grade 1 refers to hemorrhage confined to the germinal layer, grade 2 is intraventricular hemorrhage, grade 3 is intraventricular hemorrhage with ventricular dilatation, and grade 4 includes associated parenchymal hemorrhage or extension. Ultrasonographic images were videotaped and later read blinded by one of the investigators (H.L.M.) without any clinical data.

Infants who weighed ≤1500 gm underwent ultrasonographic head scans at delivery and at 1, 6, 12, and 24 hours of age and then daily for the first 7 days of

life. Infants who weighed >1500 gm had ultrasonographic head scans at the same time interval for the first 24 hours of life and then had a head scan at 7 days of life. Babies who died in the first week also had a head scan procedure immediately post mortem.

Approximately 4000 maternal and neonatal variables were collected per mother-baby pair. These variables were recorded on precoded forms, reviewed, corrected, and entered into the mainframe computer, Vax 8800 (Digital Equipment, Inc, Maynard, Mass.). The Oracle Database Management System (Oracle Corporation, Belmont, Calif.) was used. Extensive edit checks were programmed and run after data entry, and errors were corrected accordingly.

The effect of labor in women who underwent cesarean section with regard to periventricular-intraventricular hemorrhage or progression to grade 3 or 4 periventricular-intraventricular hemorrhage in the neonate was examined. Hemorrhages detected within 1 hour of age were arbitrarily defined as early hemorrhage and those detected later than 1 hour of age were referred to as late hemorrhage.

Maternal obstetric and neonatal factors were then analyzed for their relationship to periventricular-intraventricular hemorrhage. Continuous variables were compared by one-way analysis of variance among those infants with no hemorrhage or periventricular-intraventricular hemorrhage. Categoric variables were compared by χ^2 analysis and Fisher's exact test when appropriate. A p value of <0.05 was considered significant.

Results

We studied 106 infants of 85 women who were delivered by cesarean section. There were 16 pairs of twins, with the first twin of one woman not enrolled in the study. There was no significant difference in the distribution of infants in any of the subgroups by weight among the three groups (Table I). Periventricular-intraventricular hemorrhage occurred in 45 of the 106 infants (42.4%) and in 39 of 86 infants (45.3%) with birth weights ≤1500 gm. Table II describes the entire group of mothers who had cesarean section and their infants. The mean birth weight was 1210 ± 351 gm and the mean gestational age was 29.5 ± 2.7 weeks.

Forty-one percent of the infants were exposed to antenatal steroids and 33% to tocolytic agents. Fifty percent of the infants left the delivery room intubated. Table III categorizes the infants as to whether periventricular-intraventricular hemorrhage developed. The infants with development of periventricular-intraventricular hemorrhage were lighter (1072 ± 336 vs

1313 ± 330 gm, $p = 0.000$) and were less advanced in gestation (28.4 ± 2.8 vs 30.3 ± 2.4 weeks, $p = 0.000$), when compared with the infants without development of hemorrhage. The frequency of periventricular-intraventricular hemorrhage was similar in infants whether they did or did not receive antenatal steroids or tocolytics. Cord blood hematocrits were also significantly lower in the infants with development of periventricular-intraventricular hemorrhage ($p = 0.007$). A lower frequency of hemorrhage occurred in female (33.3%) as compared with male (54.3%, $p = 0.049$) infants. Table IV lists the age at which the periventricular-intraventricular hemorrhage was first detected. Ninety percent of the entire group of infants had the initial head ultrasonographic examinations performed in the first 20 minutes of life. Only 3.9% had the initial examination performed >30 minutes from birth. Periventricular-intraventricular hemorrhage had already occurred at the time of the initial head ultrasonography in 20.0% of all the infants who had periventricular-intraventricular hemorrhage. By 12 hours of life, another 17.7% of the infants had had periventricular-intraventricular hemorrhage. However, in 24 (53.4%) of the 45 infants with hemorrhage, it occurred at ≥48 hours of life. The hemorrhage occurred after 72 hours of life in only 6.6% of these infants. Table V shows the timing of onset of the hemorrhage in the groups of active-phase labor (cervical dilatation ≥4 cm), latent-phase labor (cervical dilatation <4 cm), and no labor. There were no significant differences in the time that the periventricular-intraventricular hemorrhage developed between the three groups.

Table VI reports the primary indication or diagnosis of the women who had cesarean section and the frequency of periventricular-intraventricular hemorrhage. The primary indication for cesarean section was breech presentation in 36 of 106 infants (34.0%). Another 28 (32.1%) mothers had pregnancy-induced hypertension, and 17 infants (16.0%) were delivered by cesarean section because of fetal distress. There were no significant differences in the frequency of periventricular-intraventricular hemorrhage with regard to maternal diagnosis.

The frequency of periventricular-intraventricular hemorrhage is compared between twins in Table VII. The frequency of periventricular-intraventricular hemorrhage and progression to grade 3 or 4 hemorrhage was not significantly different between the first and second twins.

The effect of when during labor the mother had cesarean section is shown in Tables VIIIA and VIIIB. The overall frequency of hemorrhage, the frequency of early or late hemorrhage, and the initial frequency of grade 3 or 4 hemorrhage were similar among the three groups. However, progression of hemorrhage, progression to grade 3 or 4 hemorrhage, and total fre-

quency of grade 3 or 4 hemorrhage were significantly higher in the active-phase labor group as compared with the latent-phase and no-labor groups.

Table IX gives the initial and final grades of periventricular-intraventricular hemorrhage of the two groups. Excluding infants whose initial hemorrhage was grade 3 or 4, only 2 of 27 infants (7.7%) in the no-active-phase labor group had progression to grade 3 or 4 hemorrhage compared with 8 of 12 (66.7%) in the active-phase labor group ($p = 0.000$).

Table X examines the mean birth weight of the groups compared with early or late hemorrhage and progression of hemorrhage. The infants who did not have periventricular-intraventricular hemorrhage had significantly higher birth weights than did the infants who had periventricular-intraventricular hemorrhage. The infants who had progression of hemorrhage were more likely to have lower weights.

Of additional interest is the effect of early hemorrhage on the progression of periventricular-intraventricular hemorrhage. Six of the 12 infants (50%) who had development of periventricular-intraventricular hemorrhage ≤1 hour of age had hemorrhage that progressed one or more grades, as compared with 6 of 33 infants (18.2%) who developed periventricular-intraventricular hemorrhage >1 hour of age ($p = 0.043$).

Comment

As expected, the infants with development of periventricular-intraventricular hemorrhage weighed less and were less advanced in gestation as compared with the infants in whom periventricular-intraventricular hemorrhage did not develop. In addition, fewer female infants experienced periventricular-intraventricular hemorrhage. There were no differences in frequency by maternal diagnosis, breech presentation, twins, tocolytic therapy, or antenatal steroids. A similar percentage of infants received antenatal steroids in the active-labor and in the no-labor groups. As expected, the number of infants who received tocolytic therapy was less for those whose mothers were not in active labor (18 of 78 infants, 23.1%) than for those whose mothers were in the active phase of labor (17 of 27 infants, 62.9%, $p < 0.001$). Cord blood gas values were similar in the hemorrhage and no-hemorrhage groups. Cord blood hematocrit values were significantly lower in the infants with periventricular-intraventricular hemorrhage. In infants with early periventricular-in-

traventricular hemorrhage the low cord blood hematocrit may be due to the hemorrhage itself. However, cerebral blood flow increases with a decreasing hematocrit[9] so that a low cord hematocrit may be a predisposing factor to the development of periventricular-intraventricular hemorrhage.[10] We concur with others[2, 5] and remain surprised at the small role obstetric factors appear to have with regard to the development of periventricular-intraventricular hemorrhage. In this article we focused on when it occurred and the progression and overall frequency of grade 3 or 4 hemorrhage. The time when periventricular-intraventricular hemorrhage occurs is most important with regard to the development of therapeutic interventions. If a large percentage of hemorrhages are present at delivery, the intervention, such as drug administration to the mother, would need to start before delivery. On the other hand, if only a small percentage of hemorrhages are present at birth, then intervention directed at the neonate would be appropriate. Additionally, we need to study the relationship of the time when hemorrhage occurs with regard to progression of hemorrhage.

Severe hemorrhage (grade 3 or 4) has a much higher mortality and a much higher frequency of neurologic deficit associated with it. Previous reports of infants who survived with grade 3 or 4 hemorrhage indicated a 50% to 75% frequency of neurologic deficits[8, 11] compared with a 15% frequency in the infants who survived grade 1 or 2 hemorrhage.[12] Although some recent reports are more optimistic, grade 3 or 4 hemorrhages are still associated with a high percentage of neurologic deficits in the infants.[13, 14]

The frequency of early hemorrhage and overall frequency of periventricular-intraventricular hemorrhage was not different in the infants whose mothers were in active-phase labor as compared with infants whose mothers were not in labor. We were surprised to find that there were no significant differences in the time that the three groups developed periventricular-intraventricular hemorrhage. From our previous report,[7] we expected that the infants whose mothers were in active labor at the time of cesarean section would have a higher percentage of early hemorrhage, less late hemorrhage, and the overall frequency of hemorrhage the same when compared with the other two groups. However, the frequency of early hemorrhage varied from three of 46 infants (6.5%) in the no-labor group to five of 27 infants (18.5%) in the active-phase labor group. Additionally, among all infants with ultimate development of periventricular-intraventricular hemorrhage, it developed in the first hour of life in 15.8% of the no-labor group as compared with 35.7% in the active-phase labor group. We contrasted these findings to those of our previous report of 53 infants who were delivered by the vaginal route with a mean birth weight of 1298 gm; periventricular-intraventricular hemorrhage developed in 21 of 53 infants (39.6%) in the first hour of life. Additionally, of all the infants with periventricular-intraventricular hemorrhage, 75% had their hemorrhage within the first hour of life. Although

not specifically investigated in this study, these findings suggest our previous conclusions that cesarean section before the onset of active-phase labor is protective for early periventricular-intraventricular hemorrhage but not for overall frequency of hemorrhage. Additionally, vaginal delivery accelerates the time when hemorrhage occurs but does not affect the overall frequency of hemorrhage. Active-phase labor may well fit between these two points on a continuum with some effect on the frequency of early hemorrhage but certainly not to the same degree as vaginal delivery.

In 17 of the 45 infants (37.7%) the final grade of hemorrhage was 3 or 4. The initial hemorrhage in 7 of the 17 infants was grade 3 or 4, and 10 other infants had progression of hemorrhage to grade 3 or 4. Seven (22.5%) of the 31 infants who were delivered before the active phase of labor (latent-phase and no-labor groups) had periventricular-intraventricular hemorrhage grade 3 or 4 hemorrhage. The initial hemorrhage in five of the seven infants was grade 3 or 4. Only two of 26 infants (excluding the five infants whose initial hemorrhage was grade 3 or 4) had progression of hemorrhages to grade 3 or 4. In contrast, 10 of the 14 infants (71.4%) who experienced active-phase labor had grade 3 or 4 hemorrhage (p = 0.006). Two infants had initial hemorrhages that were grade 3 or 4, whereas eight other infants had progression of hemorrhage to grade 3 or 4 (p = 0.022). A recent study was reported on 49 infants who had a head ultrasonographic scan done immediately after birth or after admission to the neonatal intensive care unit.[15] Twenty of the 49 infants were delivered by cesarean section. Of the 20 infants with periventricular-intraventricular hemorrhage, 6 (30%) had hemorrhage detected at the initial head ultrasonographic scan. Thirteen of the 20 (65%) had progression of hemorrhage. In four large studies (Table XI), 42% of the infants with periventricular-intraventricular hemorrhage had grade 3 or 4 hemorrhage.[2, 16-18] Our frequency of 37.5% of grade 3 or 4 hemorrhage is similar to the incidence in these studies. However, the frequency of severe hemorrhage of 22.5% in the infants who were not in active-phase labor was half of that reported in these large series. We feel that absence of the active phase of labor is protective against progression to severe hemorrhage. It is of great interest that 6 of 12 infants (50%) with periventricular-intraventricular hemorrhage that developed at ≤1 hour of life had progression of hemorrhage compared with only 6 of 33 infants in whom it developed at >1 hour of age (p = 0.043). If this holds true, then any factor or factors that cause periventricular-intraventricular hemorrhage during labor, at the time of delivery, or in the first hour of life would also cause an increased frequency of progression of hemorrhage.

If cesarean section before the active phase of labor prevents progression to severe periventricular-intraventricular hemorrhage, should more cesarean sections be performed in the preterm infants to prevent progression to severe hemorrhage? The answer is no. Table XII gives the indication for delivery of 321 liveborn infants with birth weights <1000 gm unrelated to this study. We examined these indicators for the practicality of cesarean section at ≤4 cm. In women who undergo cesarean section because of incompetent cervix, the cervix is usually dilated to ≥4 cm at the time of admission. Most women with preeclampsia or eclampsia ≤1500 gm are delivered by cesarean section. Essentially, all immature infants whose mothers have placenta previa or abruptio placentae are delivered by

cesarean section. No one would advocate cesarean section in women with preterm labor before a cervical dilatation of 4 cm in an attempt to decrease the progression of periventricular-intraventricular hemorrhage after delivery.

Premature rupture of members is the only diagnosis that would lend itself to changes. However, to plan preterm delivery and expose the neonate to serious problems of prematurity in the hope of preventing a single serious problem would seem unwarranted.

We do not feel that our study supports any change in the route of delivery of the preterm infant.

Discussion

DR. JAMES A. LOW, Kingston, Ontario, Canada (Fellow). Recent progress in our knowledge of perinatal brain damage and its underlying pathogenic mechanisms has been due, in part, to the increasing use of imaging techniques to monitor the development and evolution of pathologic lesions of the brain in surviving newborn infants. This report was designed to demonstrate that active labor in preterm pregnancy with a fetus <1750 gm will increase the frequency, timing, and severity of periventricular-intraventricular hemorrhage in the newborn. Analysis of the data derived from 106 preterm newborns delivered by cesarean section has demonstrated no significant difference in either the frequency or the timing of periventricular-intraventricular hemorrhage in the active-labor group in relation to the no-active-labor group. Therefore the authors have focused their attention on the severity of the periventricular-intraventricular hemorrhage as expressed by the final grade during the week after delivery. Analysis indicates that the incidence of grades 3 and 4 periventricular-intraventricular hemorrhage in the active-labor group is significantly greater than in the no-active-labor group (Table IX). However, three issues should be considered before this interpretation is accepted.

Active labor is the central question in this study. The discrimination between the no-labor group ($n = 46$) and the active-labor group ($n = 27$) is clear. However, the latent-labor group ($n = 33$) could represent a confounding factor. Active labor was defined as beginning when the cervix dilated to 4 cms. If we assume there are multiple observers, have these observations been consistent throughout the study? Do the authors have data with regard to the duration of uterine activity or the total amount of uterine work in the patients of the latent-labor and active-labor groups? For example, in respect to the stress to the fetus, is there a difference between a patient with 8 hours of latent labor resulting in cervical dilatation of 3 cm and a patient with 3 hours of active labor resulting in cervical dilatation of 5 cm? Would the interpretation of the association of grades 3 and 4 lesions change if the latent-labor group was either excluded or transferred to the active-labor group?

The possibility of confounding clinical variables must be considered. The authors state that approximately 4000 maternal and neonatal variables were collected per mother and baby pair. Maternal obstetric and neonatal variables were then analyzed for their relationship to periventricular-intraventricular hemorrhage. The association of birth weight, newborn sex, and cord he-

matocrit with periventricular-intraventricular hemorrhage is noted in Table III. Should it be assumed these represent the only significant clinical variables associated with periventricular-intraventricular hemorrhage? Newborn complications in particular are important because the final grade of periventricular-intraventricular hemorrhage occurred during the week after delivery. Associations with periventricular-intraventricular hemorrhage have been demonstrated for newborn respiratory complications[1] and newborn hypotension.[2,3] Thus the possible associations of newborn respiratory distress syndrome, pneumothorax, newborn hypoxemia, and newborn hypotension, and hypertension should be examined. A logistic regression analysis to determine the association of active labor, birth weight, and any relevant newborn complications to periventricular-intraventricular hemorrhage would help to justify the conclusion that there is a significant association between active labor and the final grade of the periventricular-intraventricular hemorrhage.

The authors are to be commended for the carefully scheduled series of head ultrasonographic scans beginning during the hour after delivery. This protocol has provided documentation of the time of the first ultrasonographic evidence of periventricular-intraventricular hemorrhage in each child, within the limits of the sensitivity of cranial ultrasonographic examinations.

The final grade of the periventricular-intraventricular hemorrhage was defined according to the criteria of Papile et al. The significant observation identified by the authors was an increased incidence of grades 3 and 4 periventricular-intraventricular hemorrhage in the active-labor group. However, examination of the data in Table IX indicates that the frequency of grade 4 is of the same order in the active-labor and no-active-labor groups. The contiguous hyperechoic lesion in the parenchyma of the brain identified by ultrasonographic examination (classified as grade 4) represents in most cases hemorrhagic periventricular leukomalacia rather than a direct extension of a germinal matrix hemorrhage.[4] Were there other ultrasonographically demonstrated parenchymal lesions in these newborns? If so, these parenchymal lesions should be considered as a separate group. Thus the association between active labor and the severity of periventricular-intraventricular hemorrhage is based on an increased number of grade 3 in relation to grade 2 lesions in the active-labor group compared with the no-active-labor group. Is the degree of ventriculomegaly that discriminates the grade 3 from the grade 2 lesions substantive?

The significance of a positive finding would be an increase in elective cesarean sections in the delivery of preterm pregnancies. The authors concluded that more cesarean sections should not be performed to prevent periventricular-intraventricular hemorrhage because the current indications in these patients would not justify such intervention. In view of the data presented in this study, would it not be more appropriate to conclude that the evidence for severe hemorrhage because of active labor is not sufficiently compelling to justify such aggressive intervention?

Dr. Thomas H. Kirschbaum, Bronx, New York. Dr. Anderson, it seems to me you presented a series of women in preterm labor, some of them anticipating vaginal delivery, who had complications of labor sufficiently compelling to result in cesarean section. How do you separate the effect of the indications for cesarean section from the impact of the procedure itself in terms of the differences you noted?

Dr. Valerie Parisi, Houston, Texas. Dr. Anderson, on the neonatal side of the coin, if you eliminate the babies who had hemorrhage diagnosed within the first hour of life and look at the rest of the babies, was there any effect of maximum ventilator settings or time on the ventilator in the incidence or progression of hemorrhage in those babies?

Dr. Mortimer Rosen, New York, New York. I have one question. There is a suggestion that the lowest-birth-weight babies were in the vaginal delivery group. If one looks at individual birth weights, not at 1700 gm but going down to 500 and 600 gm, in clinical practice it is more common for that baby to be delivered vaginally, one, because it comes out more quickly, and two, because the obstetrician doesn't want to do a cesarean. Could that have confounded your results?

Dr. Paul G. McDonough, Augusta, Georgia. A statistical estimation of the difference between normal and abnormal afforded by the test system would facilitate data interpretation. Do you have some measure of ultrasonographic intraobserver and interobserver variability in attempting to distinguish between normal and the various grades of hemorrhage?

Dr. Steven G. Gabbe, Columbus, Ohio. Dr. Anderson, did you screen mothers for a history of anticoagulant use? Particularly, did you find out if these mothers had used aspirin?

Dr. Anderson (Closing). With regard first to the questions that Dr. Low asked, and I guess the most important one concerns the indications we now consider with regard to cesarean section, that we shouldn't do more cesarean sections or whether there is sufficient evidence that active-phase labor leads to severe hemorrhage.

I think that there is reasonable evidence, although

the numbers are small, that in either vaginal delivery or cesarean section, if the infants have experienced active labor, there is a higher incidence of grade 3 or 4 hemorrhage.

Although not mentioned in this presentation with regard to neonatal complications, if one group of infants was sicker than the other, it was the infants who were not subjected to active labor. In the infants who did not undergo active labor, 14 of the 79 infants died. In the active-labor group there was one death. This didn't quite reach clinical significance, but if there was any skewing of the two groups, the infants not subjected to active labor were the sicker of the two groups.

With regard to latent labor and what would happen if we lumped the groups on either side, certainly, if we take out the latent-phase group, there is still a significant difference comparing just the active-phase and the no-labor groups. If we put the latent-phase group in with the active-phase labor group, it is also still significant. I think that the latent-phase group is interesting, but they certainly are much more like the women who have not had labor as compared with the active-phase labor group. With regard to the results of severe hemorrhage in our study, there were more in the grade 3 than the grade 4 category and what does this mean? I think in most of the studies, when the criteria of Papile et al. are used and the number of survivors is examined, there are likely to be more in the grade 3 than the grade 4 category.

Dr. Kirschbaum asked whether the indication for cesarean section had an impact on the study. Was the severity of the condition the reason for cesarean section? Again, because the less-sick infants were the active-phase group, this should not have affected the outcomes that we found.

Dr. Parisi asked if we looked at what happened in the neonatal course among the three groups. Among the first 150 infants studied, delivered both vaginally and by cesarean section, if the infants who had hemorrhage within the first hour of life are taken out, certainly there is no difference in major neonatal complications among the infants who did or did not have intraventricular hemorrhage.

A question was asked about all the other variables. We have now looked at all 230 infants we studied and evaluated obstetric variables with regard to frequency of hemorrhage; basically we have found that only cord blood hematocrit, male gender, and active-phase labor were the only variables that are associated with early hemorrhage.

Dr. Rosen asked about the birth weights within the three groups. At least in this study, by 250 gm increments, there were no significant differences among the three groups with regard to birth weights. In the previous study there also were significant differences by 250 gm increments. So there was not a significantly higher incidence of very-low-birth-weight infants in the group delivered vaginally.

I'm not sure I exactly understand the question about ultrasonography other than to say the clinicians taking care of the patient looked at the results and used them for clinical management. All the ultrasonographic scans were read in a blinded manner by one of the participants in the study with absolutely no clinical data about the infants.

In regard to Dr. Gabbe's question about aspirin, yes, we did screen for aspirin in this study and got a lower instance than we would suspect. I've forgotten the exact number, but there were no substantial differences among the three groups with regard to mothers ingesting aspirin.

Leadership qualities of obstetrics and gynecology department chairmen of United States medical schools

G. William Bates, MD, and Dawn W. Blackhurst, MS
Greenville, South Carolina

OBJECTIVE: The purpose of this study is to examine leadership qualities, preparation for leadership, and perceptions of skills needed for academic leaders in obstetrics and gynecology.
STUDY DESIGN: Chairmen and acting chairmen of the 122 United States medical schools with residency training programs in obstetrics and gynecology were surveyed about the stated objectives of the study. Differences in proportions were analyzed by means of the χ^2 test; the Student *t* test was used to compare mean ranks.
RESULTS: Information was obtained from 98 (80.3%) of those surveyed. Interpersonal skills and knowledge of the specialty were identified as most important qualities leading to appointment; financial management skills were identified as most frequently lacking. Having a mentor prior to appointment was found to be associated with several characteristics. Those chairmen who had mentors were more likely to have these characteristics: (1) to have completed a subspecialty fellowship, (2) to command a larger departmental budget (>$4 million), (3) to have been a board examiner before appointment, and (4) to have received support in obtaining their appointment from recognized leaders in the specialty.
CONCLUSION: Current academic leaders in obstetrics and gynecology must identify and prepare protégés (protégées) for future leadership roles. (Am J Obstet Gynecol 1992;166:1102-16.)

Key words: Leadership skills, mentor

Development and selection of corporate leaders is a frequent topic in the management literature.[1-4] However, few studies are published on the development and selection of leaders in medical academia.[5-8] Prentice wrote, "Attempts to analyze leadership tend to fail because the would-be analyst misconceives the task. Leadership is usually not studied at all. Popularity, power, showmanship, and wisdom in long-range planning are studied instead. Some leaders have these things, but they are not of the essence of leadership. The leader's *unique* achievement is a human and social one which stems from understanding fellow workers and the relationship of their individual goals to the group that must be carried out."[9]

The tasks that confront chairmen* of clinical departments of medical schools are continually increasing and changing.[10] Chairmen are expected to direct undergraduate, residency, and subspecialty fellowship educational programs, lead basic and clinical research programs supported by extramural funding, preside over a large clinical practice that generates funds for faculty support and institutional survival, serve on institutional committees, maintain a national presence and reputation, and manage the personnel and fiscal affairs of the department. Moreover, clinical departmental chairmen must stay abreast of federal and state health care reimbursement schemes, accreditation requirements for educational programs and research laboratories, and patient admission policies of hospitals and ambulatory settings.

No one can be fully prepared for such a multifaceted position. Yet most men and women who are selected as chairmen of medical school departments of obstetrics and gynecology thrive in the position and serve for >5 years. The purpose of this study is to examine leadership qualities, preparation for leadership, and perceptions of skills needed for academic leaders in obstetrics and gynecology.

Material and methods

Information was gathered by survey (see appendix) of current and acting chairmen of departments of obstetrics and gynecology of United States medical schools with residency training programs. Chairmen were identified as those listed in the *AAMC Directory of American Medical Education, 1990-91*.[11] Surveys were mailed to each current and acting department chairman (N = 122) with a cover letter explaining the purpose of the survey and requesting that the questionnaire be returned within 21 days of receipt.

Items that were scaled according to rank were assigned a value of 1 to the most important item and a value that constituted the number of items to be ranked as the least important (i.e., seven items to be ranked so a value of 7 indicates least importance). When a rank was not assigned at all, the value of least importance was inserted for calculation of mean ranks.

Differences in proportions were analyzed with the χ^2 test.[14] The Student t test was used to compare mean ranks.[15] A value of $p \leq 0.05$ was considered to be statistically significant. All data analysis was performed with SAS statistical software (SAS Institute Inc., Cary, N.C.).

Results

Surveys were returned from 98 of the 122 chairmen who were identified for the study, resulting in an overall response rate of 80.3%. The mean ± SD age of respondents at the time of survey was 54.9 ± 6.8 years (range 37 to 71 years). More than half of the respondents (57%) were between 50 and 59 years old (Table I).

Twenty percent of the respondents had held more than one position as chairman, and most (63%) were working in a public medical school setting. The majority of respondents (66%) reported that they were acting as a mentor for a junior faculty member. Sixty-three percent considered themselves to be recognized leaders in their field (Table I).

Sixty-two percent of the chairmen were subspecialty certified compared with only 4.8% of all physicians certified in obstetrics and gynecology. Of the 61 chairmen holding subspecialty certification, 43% were certified in maternal-fetal medicine, 26% in reproductive endocrinology, and 31% in gynecologic oncology (Table II). This distribution is similar to the distribution of all subspecialists certified in the three subspecialties.

Training characteristics of the respondents before appointment are presented in Table III. Fifty-one percent had completed a subspecialty fellowship, 58% had been division directors, and 58% had been externally appointed. The majority of respondents (49%) were 40 to 49 years old when appointed (mean ± SD 46.3 ± 6.8, range 34 to 68). Most (76%) had achieved the highest academic rank (professor) before appointment.

Sixty-one percent reported that they had a mentor during their training, and 42 (43%) reported that they had received support from nationally recognized leaders in obtaining their appointment (Table III). Support consisted of letters of recommendation (86%), nominations for chairmanships (64%), and appointments to committees and organizations (36%).

Several statistically significant associations were found between training characteristics and age at the time of survey (Fig. 1). Younger chairmen (<50 years) were more likely than older chairmen (≥50 years) to be subspecialty certified (86% vs 56%, $p = 0.01$); younger chairmen were more likely to have completed a subspecialty fellowship (76% vs 44%, $p = 0.009$) and were *less* likely to be serving as mentors for junior faculty (38% vs 75%, $p = 0.001$).

Age was also found to be significantly associated with area of subspecialty certification (Fig. 2). Younger chairmen were more likely to be certified in maternal-fetal medicine (61% vs 35%) and reproductive endocrinology (33% vs 23%), whereas older chairmen were

more likely to be certified in gynecologic oncology (42% vs 6%, $p = 0.02$).

In ranking the importance of leadership qualities and skills leading to appointment, respondents felt that interpersonal skills and knowledge of specialty were most important (Table IV). However, in the role of advising others, respondents ranked administrative skills as the most important skill requiring emphasis, followed by interpersonal skills. Two statistically significant differences were found between the mean rank of qualities leading to appointment and qualities stressed when advising others. Teaching skills were ranked significantly lower in importance when advising others ($p = 0.01$), and financial management skills were ranked significantly higher ($p = 0.001$).

Respondents were also asked to identify qualities that were lacking in themselves but that they thought were needed in the role of chairman. Financial management skills, political awareness, administrative skills, and research experience were identified as the four most lacking skills (67%, 39%, 32%, and 18%, respectively) (Table V).

The importance of support and experiences encouraged by mentors is presented in Table VI. For those chairman who had a mentor before appointment, providing administrative duties and gaining introductions to specialty leaders were ranked as the two most important areas stressed by their mentors. In serving as mentors to others, these same chairmen reported the two most important areas to be assumption of administrative duties and encouragement of research productivity.

Mentorship was found to be significantly associated with several training characteristics (Fig. 3). Those chairmen who had a mentor before their appointment were more likely to control a larger departmental budget (>$4 million) ($p = 0.002$), to have completed a subspecialty fellowship ($p = 0.008$), to have received support in obtaining their appointment from recognized leaders in the field ($p = 0.03$), and to have been an examiner for the American Board of Obstetrics and Gynecology, Inc., before their appointment ($p = 0.03$).

Several associations were found between size of department budget and training characteristics (Fig. 4). Those chairmen who were in charge of budgets in excess of $4 million were more likely to be subspecialty certified ($p = 0.03$), to have completed a subspecialty fellowship ($p = 0.001$), and to have been division director before appointment ($p = 0.03$).

Importance of leadership qualities and skills by

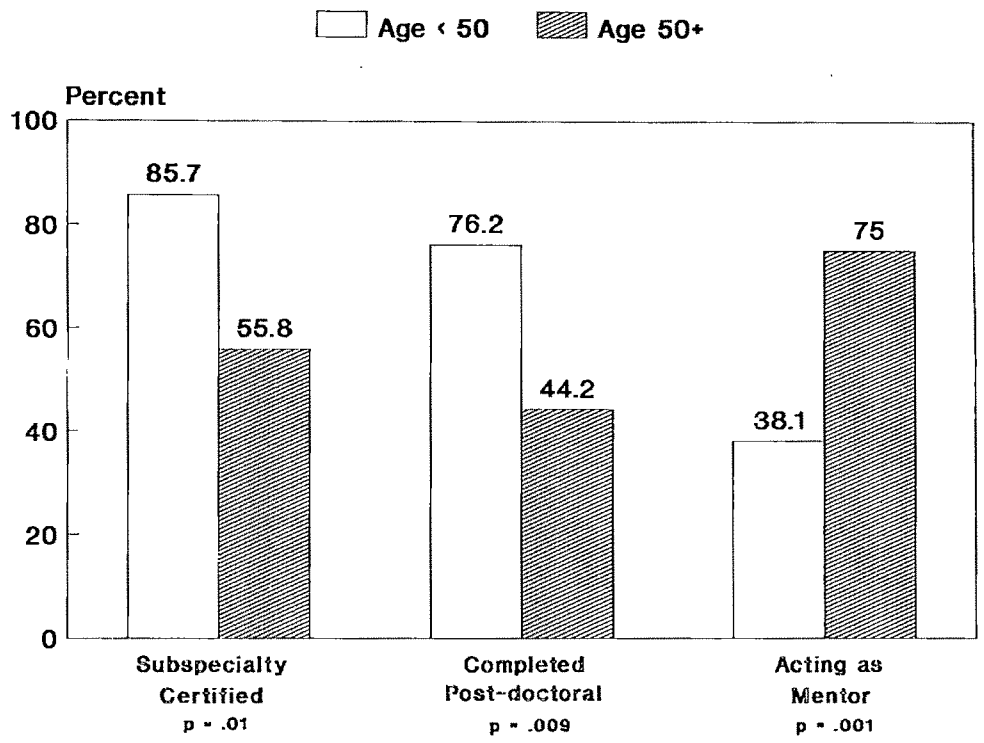

Fig. 1. Characteristics of chairmen by age at time of survey. p Value from χ^2 test for difference in proportions.

length of tenure in the chair is presented in Table VII. Chairmen holding office ≤2 years believed that respect within the specialty was the most important quality leading to their appointment. Those holding office 3 to 9 years thought that knowledge of the specialty was the most important quality, whereas those holding office ≥10 years ranked interpersonal skills as the most important of skills leading to appointment. In helping to develop skills in others, those holding office >10 years ranked knowledge of the specialty as the most important quality. However, those serving for <10 years thought that administrative skills were most important. The skill found to be most frequently lacking among all chairmen, regardless of length of tenure, was skill in financial management. In ranking skills that were encouraged by their mentors, all chairmen ranked administrative skills as most important.

Before appointment, all 98 (100%) of the respondents belonged to the American College of Obstetricians and Gynecologists. After appointment to chairman, 25 respondents (26%) became members of The American Gynecological and Obstetrical Society; 16 respondents become members of the Association of Professors of Gynecology and Obstetrics. The distribution of total membership within each society is presented in Table VIII.

The dean of the medical school was the most sought after individual for advice pertaining to the respondent's chairmanship (35% ranked as No. 1) (Table IX). Other persons often asked for advice were chairmen of other departments or other senior faculty members in obstetrics and gynecology. Very few respondents sought advice from outside of the medical school.

Only 49 (50%) of the respondents reported that they had been provided with opportunities by their medical school to learn management principles after their appointment. Of these 49, 59% had taken management short courses, 47% had attended Association of American Medical Colleges leadership seminars, and 39% had attended teaching workshops. (Totals exceed 100% because of multiple responses.)

Eighty-seven percent recommended that newly appointed chairs take a short course (2 to 16 weeks) in administration and financial management. However, only 28% of those recommending a short course had actually taken such a course. The majority of chairmen (83%) felt that national organizations in obstetrics and gynecology should develop leadership workshops. Most (77%) responded that the Associations of Professors of Gynecology and Obstetrics would best serve this need.

The majority of respondents (65%) believe that the traditional academic search committee is an effective method for selecting academic leaders. However, several criticisms of the traditional search committee were addressed by the respondents. Most criticisms were directed at the following issues: (1) There is a lack of

representation from members of the specialty of obstetrics and gynecology; (2) the search process is too slow; (3) the search committee may not be aware of the special needs of a department of obstetrics and gynecology; (4) there may be conflicting interests of search committee members.

Comment

"Successful corporations don't wait for leaders to come along. They actively seek out people with leadership potential and expose them to career experiences designed to develop that potential. Corporations that do a better-than-average job of developing leaders put an emphasis on creating challenging opportunities for relatively young employees."[16]

Leaders in academic medicine emerge from those who distinguish themselves in research and—to some extent—in teaching and clinical skills.[17] However, unlike in corporations, where careers begin in a person's mid-20s, in academic medicine one's career does not begin until age 30 or beyond. Therefore the preparation of future leaders in academic medicine begins relatively late.

In our opinion the most important finding from this study was the role of the mentor in developing the qualities and skills needed to become chairman of a department of obstetrics and gynecology. When Ulysses, King of Ithaca, picked his friend Mentor to advise his son Telemachus, the role of the mentor was established.[18] According to Levinson,[19] the mentor is teacher,

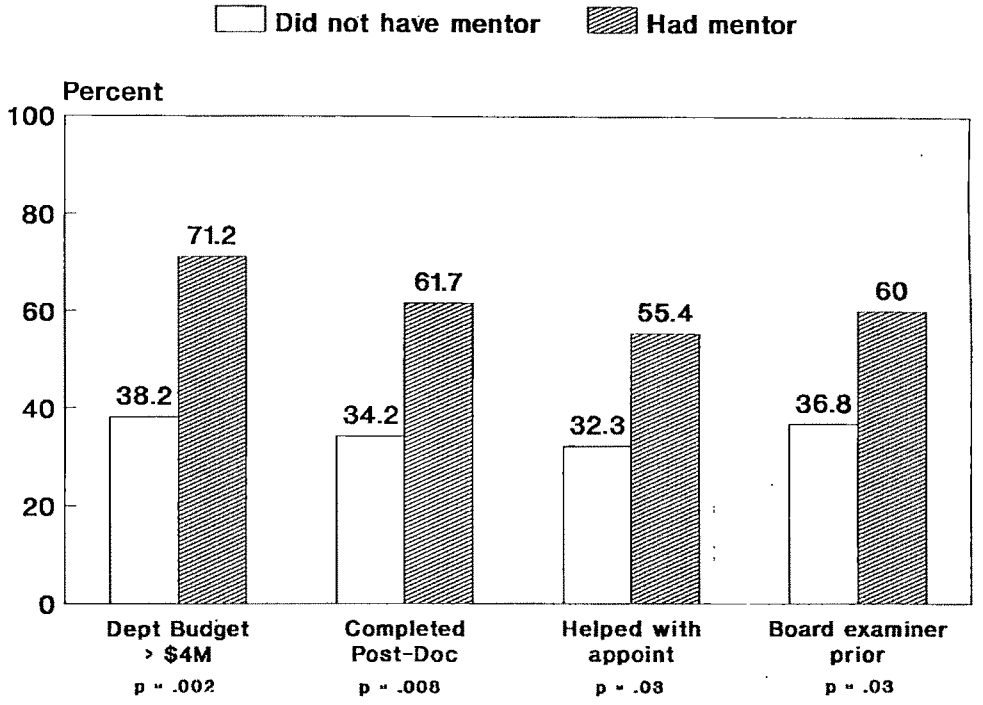

Fig. 3. Chairmen characteristics by mentorship. p Value from χ^2 test for difference in proportions.

counselor, sponsor, developer of skills, guide, and exemplar.

Departmental chairmen who had mentors before appointment were more likely to command department budgets in excess of $4 million, were more likely to have completed a subspecialty fellowship, and were more likely to have received support from recognized leaders in the specialty in obtaining their appointment.

The most important skill that chairmen reported their mentors had stressed to them was assumption of administrative duties, followed in importance by introductions to leaders in the specialty. However, when *serving* as mentors, department chairmen thought that encouragement of research productivity was the second most important experience to enhance in their protégés (protégées), followed by introductions to leaders in the specialty.

Department chairmen who had mentors were also more likely to be examiners for The American Board of Obstetrics and Gynecology, Inc., before their appointment as chairman. This finding may reflect the influence of the mentor and the support of leaders in the specialty in promoting emerging academic leaders to become board examiners.

The importance of mentors in developing future leaders of corporate enterprises is stressed in the management literature[20] and is now becoming stressed more frequently in the development of academic leaders.[21, 22] The classic mentor-protégé relationship in academic medicine is the relationship between William Osler and Harvey Cushing.[23] Academic leaders who have an enduring reputation are often remembered for their development of other academic leaders. Some medical schools and individual departments are noted for the production of academic leaders to fill leadership positions in other institutions.[24]

In this study 66% of chairmen reported that they were serving as mentors for future academic leaders. However, only 38% of chairmen under age 50 were serving as mentors, while 75% of those chairmen older than age 50 were serving as mentors for future aca-

demic leaders. It is not surprising that younger chairmen are less likely to serve as mentors because they may need several years on the job as chairmen to establish credibility with faculty, to gain self-confidence, and to identify potential leaders. However, a newly appointed chairman should not wait too long to assume the mentor role.

We could not discern from this study when or how in a person's academic career the mentor-protégé (protégée) relationship was established. For the protégé (protégée) the relationship coulde begin as early as medical student days, during residency training, during the subspecialty fellowship, or on becoming a faculty member. We suspect that an early relationship fosters thoughtful career development. The mentor can serve as a role model in many academic areas such as teaching, basic and clinical research, and clinical practice. The mentor can open the door for the protégé (protégée) to meet leaders in the specialty and to participate in the activities of academic societies. The mentor can make the protégé (protégée) aware of career opportunities that will lead to career advancement.

Although it is the common belief that a mentor (or mentors) has a positive effect on an individual's career development, there are possible negative effects as well. If the mentor is not held in high esteem within the specialty, he or she may not be able to provide an entrée for the protégé (protégée). If the protégé (protégée) becomes a threat to the mentor, an adversarial relationship may develop, which may tarnish the mentor and/or the protégé (protégée). The mentor may provide poor career guidance with resultant negative consequences for the protégé (protégée).

We have no indication from this study as to how women chairmen and emerging women leaders in academic obstetrics and gynecology find mentors to guide career development. Kronik[20] emphasizes the importance of men serving as mentors for women faculty members until large numbers of women reach top academic administrative positions. He also advocates women serving as mentors for men.

Speroff[25] reported a decade ago on the tasks of chairmen of obstetrics and gynecology departments of medical schools and on the leadership qualities of chairmen. He emphasized the changing demands away from the chairman's role as teacher, clinician, and investigator and the increasing demands to provide financial resources. There have been increasing administrative demands placed on chairmen since Speroff's report. Of the chairmen responding to Speroff's questionnaire, 29% held subspecialty board certification, compared with 62% in the current study. Of the chairmen <50 years old in the current study, 86% held subspecialty board certification. This finding suggests that 10 years from now nearly all chairmen of departments of obstetrics and gynecology will hold subspecialty board certification. Moreover, younger chairmen were more likely to be certified in maternal-fetal medicine and less

likely to be certified in gynecologic oncology. The number of reproductive endocrinologists has increased slightly among the younger chairmen.

The continuing increase in subspecialists who become departmental chairmen stands in stark contrast to the proportion of all certified obstetrician-gynecologists who hold subspecialty certification (4.5%). We assume that subspecialists, as a result of a subspecialty fellowship, have formal training in basic and clinical research, which gives them an added dimension as investigators and as leaders of research teams. Moreover, subspecialty fellowship training may give added experiences in teaching resident physicians and medical students. Our study does not provide data that allow us to compare the research and teaching experiences of physicians who completed subspecialty fellowships and became chairman with those of physicians who did not complete a subspecialty fellowship.

Does this trend toward selecting as department chairmen those who have acquired subspecialty certification foreclose the chair for those who are not subspecialty certified? We hope not! Subspecialty fellowship training and subspecialty certification do not impart special leadership qualities and should not be prerequisite to the chair. Many outstanding department chairmen, present and past, have distinguished themselves in general obstetrics and gynecology as teachers, investigators, and national leaders in the specialty. Our specialty will continue to need the broad vision of the generalists to maintain the integrity of obstetrics and gynecology. Most who complete residency training in obstetrics and gynecology enter general practice of the specialty (95.5%); therefore a broad view of the specialty must be maintained in academic centers. This does not imply that subspecialists have too narrow a focus to lead a broad discipline but does mean that subspecialists who become departmental chairmen must broaden the scope of their linking as they move up the administrative ladder.

In the current study chairmen ranked interpersonal skills as the most important quality leading to their chair appointment. This was followed in importance by

Table VIII. Membership in professional organizations

Organization	Member before appointment		Became member since appointment		Total now members

Nonphysician friend	4	4.1

*Percentages are based on 98 respondents. Percentages do not sum to 100 because many respondents ranked several persons as 1.

knowledge of the specialty, administrative skills, respect in the specialty, and vision. When advising others as mentors, chairmen ranked the same five qualities as most important; however, the order of importance was changed. Administrative skills were ranked first, followed by interpersonal skills, knowledge of specialty, vision, and respect in the specialty. The qualities selected as most important are consistent with those needed to achieve the leader's role in developing an understanding of fellow workers and the relationship of individual goals to departmental goals.

The qualities identified as lacking were financial management skills, political awareness, administrative skills, and research experience. Financial management skills, political awareness, and administrative skills can be developed more fully once a person has been selected as department chairman. These skills are not essential for selection to a leadership role but are essential to success in the leadership role.[26] When asked how these deficiencies were overcome, most chairmen responded with comments such as "on-the-job training," "course work," "hard work," and "still working on it." It is clear that chairmen are striving to attain the management skills necessary to lead their departments successfully. Those who listed lack of research experience as a deficiency are unlikely to overcome this deficiency once they become chairmen.

With the increasing managerial role of department chairmen to do things other than teach, provide clinical care, and perform research, medical schools have the responsibility to provide managerial education and support for newly appointed department chairmen. Speroff wrote: "Chairs need the assistance of qualified, able business people. It is unrealistic to expect experienced performance from untrained people. Surely it is the responsibility of the medical school and hospital to see that chairs are properly instructed and assisted, and never is this need greater than with a brand-new chair."[27] Only 50% of the respondents reported that they had been provided with opportunities by their medical schools to learn management principles. Those who had opportunities to study management principles took short courses in management or attended leadership workshops sponsored by the Association of American Medical Colleges.

Eighty-three percent of the respondents answered

that national organizations of obstetricians and gynecologists should develop leadership workshops and seminars for department chairmen and potential leaders in obstetrics and gynecology. Seventy-six percent of those who advocated leadership workshops for newly appointed department chairmen reported that the Association of Professors of Gynecology and Obstetrics would best be able to serve this need. Indeed, that organization has taken the initiative to survey needs of departmental chairmen and to develop workshops for acquiring managerial skills.

From this study we see the trend moving in the direction that chairmen of departments of obstetrics and gynecology of the future will more likely have completed a subspecialty fellowship and will more likely be subspecialty board certified than those appointed a decade earlier. Moreover, with the increasing managerial responsibilities of department chairmen, it is likely that future department chairmen will have gained some administrative experience before assuming the chair. Chairmen must recognize the importance of serving as mentors for future academic leaders. Medical school deans must recognize the necessity for providing newly appointed department chairmen with opportunities for management courses and administrative support.

We are concerned that research experience and teaching skills received relatively low ranking as leadership qualities and skills that led to appointment as department chairman. Emphasis on teaching skills was not being stressed in others who are being groomed for leadership positions, but the importance of research experience was acknowledged and is being emphasized. In our opinion the specialty will be advanced by the creation of new knowledge and by the ability to impart the knowledge of the discipline to medical students and young physicians who choose obstetrics and gynecology as a career specialty. As the onerous burden of administration increases, department chairmen cannot lose sight of the academic core of obstetrics and gynecology.

"Chairman" is a troublesome term because of the potentially sexist connotations. Houle[10] reported that three fourths of two panels of women community leaders, diversified by age and race, who were consulted in 1985 and 1987 revealed a preference for the term "chairman" as the term they would most like to have applied to themselves. An equal proportion expressed strong aversion to "chairperson." Consequently, chairman is used throughout this manuscript without prejudice to refer to women and men who occupy the office of chair of a department of obstetrics and gynecology. (Adapted from Green et al.[11])

Discussion

DR. PRESTON V. DILTS, Ann Arbor, Michigan (Fellow). This is an area in which I have had some interest. I distinctly remember receiving and completing the survey and wondering about the results. It is especially interesting to be singled out in that I am one of the three who has been a chairman in three departments. I will not identify the others although I suspect they are easily recognizable.

Dr. Bates has analyzed our discipline well. There really is a wealth of data provided. Most of the data are not surprising.

The most consistent deficits in training for aspiring or new chairmen are in financial and management skills. Many chairmen and Dr. Bates recommend that such training be provided. Given the time required to attend courses sponsored by the Association of American Medical Colleges or others, perhaps Association of Professors of Gynecology and Obstetrics, The American Gynecological and Obstetrical Society, Inc., and/or the American College of Obstetricians and Gynecologists should develop programs designed for us. Association of Professors of Gynecology and Obstetrics is currently working on this.

The significant unimportant characteristic noted in the survey is teaching skill. I am puzzled because I had thought teaching to be the name of the game. I am further confused by having The American Board of Obstetrics and Gynecology, Inc., examiner status listed as highly important. Dr. Charles Hunter would be upset—one cannot examine unless one can teach.

Dr. Bates concludes that two factors seem to be most helpful in becoming a department chairman. One is being an examiner for the oral examinations of The American Board of Obstetrics and Gynecology, Inc., and the second is having a mentor. I believe these two are interrelated in that examiners are generally nominated to the board, usually by a mentor. Therefore Dr. Bates has one conclusion that states that the best way to become a department chairman is to have a good mentor or mentors. I think Dr. Bates is correct. I can name several people who have been very helpful in my own career and I answered the question yes, that I had mentors who had helped me.

The one thing Dr. Bates has not looked at, which I find a little distressing, is the issue of gender and diversity. I was able to locate my copy of the survey and find it did not ask for sex, race, or ethnic background. I suspect it would be difficult to identify ethnic background by names or return addresses. It might be possible to identify gender and race. Having said that, I am not sure what purpose it would serve because most of us can readily identify that there are very few women serving as chairmen, as well as very few minorities.

Since I feel strongly that we should represent our discipline, we must have more chairmen who are women and/or minorities. Dr. Bates acknowledges that gender is a problem. My question, and also my problem, then is how do we provide adequate mentoring for these young people so that they can become chairmen?

Clearly, in the short run, there will not be sufficient numbers of women or minorities who can be mentors for young faculty. This means that The American Gynecological and Obstetrical Society, Inc., and others must seriously look to advancing the careers of women and minorities in obstetrics and gynecology. We must have the goal of fostering, developing, and mentoring for women and minorities so they may become leaders in the discipline in the twenty-first century.

I look forward to any comments Dr. Bates may have. I very much appreciate the opportunity to discuss this interesting article. I think his conclusions are correct and represent a major area for concentration for the membership of The American Gynecological and Obstetrical Society, Inc.

Dr. Frederick P. Zuspan, Columbus, Ohio. This is a very gutsy topic for a group such as this, and I commend you for that. One thing I did learn is that 34% of the chairmen in this country probably don't do things correctly because they use the dean as their ancillary guide.

In my experience that would be the last person I would use as a confidant. I've always thought that the chairmen were the hard-core fiber of a medical school because deans sort of come and go.

The other thing I wondered if you had included in your survey, or had considered, is that most of the people in this room have probably served on the "search-and-seize" committees, and it's been my impression that people sort of weigh the volume and the content of the curriculum vitae and they look very critically at the number of publications. In other words, what type of a scientist is the individual for the appointment? None of them really ask whether the characteristics identified are present. In other words, is the candidate a good human being? Does he/she have good communication skills? Does he know how to get along with other chairmen and is he a financial genius with a master's degree in business?

I guess the question is how can we be prepared to become chairmen? That's one of the issues. Most chairmen are probably as unprepared as I was when I became chairman, and the issue is how that can be altered. Perhaps a mentor might be a solution but probably not a good one because of the perpetuation of evil or the perpetuation of error. It depends on who the mentor is.

Dr. Ronald Gibbs, Denver, Colorado. I have two brief questions. The first is did you look at current or previous research support, especially peer review in the background of the chairs? Second, you listed the rank order in leadership skills as perceived by the chairs with interpersonal skills being number one. As each chair is different, I wonder whether you could give us the information on the number of respondents listing other leadership skills as their number one choice.

Dr. Raymond H. Kaufman, Houston, Texas. One point that was not addressed, which does have some impact on the selection of the chairman, is input from the deans of the medical schools as to what they consider to be the necessary qualities for a departmental chairman. I find that some deans suffer from what I call "the dean's fantasy." They have the idea that out there is the ideal person with great administrative skills, significant research expertise, and lots of funds to bring into the department. The deans are the ones who direct the search committee as to the type of individual they want, and it would be of some interest to have an idea of exactly what our deans are looking for.

Dr. Frederick Naftolin, New Haven, Connecticut. I think you've done us a tremendous service because you've focused something that has been kind of un-

resolved, as it were, looking at what we're becoming. There is an ascendancy of the fellowship in academic medicine, and the mandatory nature of the fellowship adds 50% to each person's clinical training. There is a decline of the role of research in the discipline. When I put these two together, that is, the apparent inclusion of a fellowship as a requirement for becoming a faculty leader and chairman and the decline of research, it seems to me that this puts the burden of the maintenance of research on the subspecialty boards.

If the subspecialty boards do not do this, then the decline of research is almost assured because the addition of the 2 years of clinical training and the tremendous emphasis on the fiscal and service side of medical school departments stand to reduce us to the craftsmen that we were known to be when obstetrics was the lower third of the class.

I think the message that Dr. Bates has given us is very important, and that message is that we must incorporate research into what we consider an adequate subspecialty training.

Dr. Robert Vinchman, Fort Worth, Texas. I'm a great believer in the mentor system. I think it has a tremendous influence. However, in the British system the mentor is very specifically allied to one person. If by any chance your mentor dies, you are finished. I hope that this will not be anything that our mentors here go through.

Dr. Kamran Moghissi, Detroit, Michigan. Can you tell us whether your data indicate what happens—what is the impact of chairmanship on the chairman and what happens to career development after the chair is taken?

Dr. Martin Stone, Stony Brook, New York. I guess the discussants proved you were right in your conclusions. This is also an indictment of deans, mentors, and our organization because I haven't heard the word teaching brought up again since you said nobody was interested in it.

Dr. Bates (Closing). Thank you all for your critical and affirming questions and responses. Dr. Dilts, I appreciate your critical review of the manuscript and the comments that you have made.

I would like to make a disclaimer. I do not believe that being an examiner for The American Board of Obstetrics and Gynecology, Inc., is important to being a chairman. It's just one of the things that fell out of the data, and I think it points to the role of the mentor in the relationship with the people who become examiners and the role of the mentor in helping promote careers.

I do think though that it is important for the examiner to be an expert clinician and an expert teacher, and those should be the criteria for that selection.

The issue of gender and diversity is an extremely important one. This was an anonymous survey, and because there are and were so few women and minorities serving as chairmen, it would be easy to identify them. When I submitted the survey, I pledged to each respondent that I would not know who was responding. I do not have that information.

However, I think the important question and perhaps the most important issue to be discussed today is the fact that we need to serve as mentors for women. Today, to my knowledge, there are only five women serving in chairs, and this has been a growing number. More than 20% of the practitioners in obstetrics and gynecology are women, and approximately 50% of the residents are women. I think it's just a matter of time before women will occupy the same proportionate number of leadership positions as residency positions.

Kronik, in a very powerful article written for academicians in comprehensive universities, stated that men must mentor women now. We cannot wait for women to reach leadership roles so that younger women can have mentors, but men in positions of responsibility must begin developing women for leadership positions. I would like to emphasize that.

Dr. Zuspan, I agree with you on the folly of going to the dean as the most frequent source of advice, although I think the dean is in a position to have an overview of the entire medical school and probably is a good source of information and advice in looking at the total picture of the clinical departments, the basic science departments, and where resources can be allocated. I'm not sure deans always understand the unique needs of departments.

You asked the question, how can a person be prepared to become a department chairman except for a mentor? I think the mentor is probably the best way to get a start, but organizations such as this one and others must recognize the need to develop leadership skills in individuals so that they're not overwhelmed when they assume a chair. The Association of Professors of Gynecology and Obstetrics is now working to develop short courses for young physicians who will be moving into chairs and chairmen who are already in the position.

Dr. Naftolin raised the question about the importance of the fellowship and the fellowship programs and the board ensuring that people completing fellowships have adequate research experience. The burden of research is falling on the fellowship programs.

Dr. Gibbs asked if we inquired how much research support a chairman had before assuming the chair and while serving in the chair. I do not have those data. He also asked a question about what percentage of department chairmen ranked interpersonal skills as number one. It was >60%, and about 35% ranked all the others as most important.

Interestingly, we did find some stratification. The chairmen who had served from 3 to 9 years and >10 years were more likely to rank interpersonal skills as number one, and those who had served ≤2 years tended to rank knowledge of the specialty and respect within the specialty as number one.

Dr. Vinchman made the point that under the British system, if a person loses a mentor, he is doomed. I hope that's not the case in our system. I don't think there is

a single mentor in a person's career, but there's an evolution of mentors as people move along the line.

Dr. Moghissi asked, what is the impact of being a chairman on the chairman's career? I don't know the answer to that question, but I was impressed with the length of tenure of the respondents. More than 38 chairmen had served ≥10 years in the position. The mean age at appointment was 46 years. So, if you assume that chairmen will serve until about age 63, that's a long term for success. By comparison, the tenure of a dean is about 3.2 years today. So the chairman has much greater staying power in the position. I think that the chairman tends to develop his own skills as a chairman.

Finally, Dr. Stone, thank you for your comments. I agree we must focus on teaching. After all, we are medical schools.

Appendix

A survey of leadership qualities of chairmen of United States medical school departments of obstetrics and gynecology

1. Your age ____
2. Your age at time of appointment to first chair ____
3. No. of chairs held ____
4. Type of medical school
   Public ____ Private ____
5. Approximate current departmental budget from all sources
   <$1 Million ____
   $1-≤2 Million ____
   >$2-≤4 Million ____
   >$4-≤6 Million ____
   >$6-≤8 Million ____
   >$8-≤10 Million ____
   >$10 Million ____
6. Do you hold subspecialty certification from The American Board of Obstetrics and Gynecology, Inc.?
   Yes ____ No ____
   If yes, which subspecialty?
   Maternal-Fetal Medicine ____
   Reproductive Endocrinology ____
   Gynecologic Oncology ____
7. Do you have other subspecialty interests (urogynecology, genetics, infectious diseases, etc.)?
   Yes ____ No ____
8. Did you complete a postdoctoral fellowship?
   Yes ____ No ____
9. What was your academic rank of the time of your appointment to department chairman?
   Assistant Professor ____
   Associate Professor ____
   Professor ____
10. Were you a division director before becoming department chairman?
    Yes ____ No ____
11. Did you practice obstetrics and gynecology or general medicine in a nonuniversity or military setting before becoming chairman?
    Yes ____ No ____
    Obstetrics and gynecology ____ General medicine ____ How many years? ____
12. Was your appointment to department chairman internal (you became chairman of the department in which you were a faculty member) or external (you were recruited as chairman to another medical school)?
    Internal ____ External ____
13. Which qualities, skills, and experiences did you have before becoming chairman that led to your appointment as chairman? Please rank in order of importance and give an indication of the relative importance (essential, important, or less important).
    Rank
    ____ Vision
    ____ Knowledge of specialty
    ____ Respect within specialty
    ____ Teaching skills
    ____ Research experience
    ____ Communication skills (language fluency)
    ____ Interpersonal skills
    ____ Political awareness
    ____ Social skills
    ____ Administrative skills
    ____ Budget and financial management skills
    ____ Other (specify)
14. Did you have a mentor before becoming department chairman?
    Yes ____ No ____

continued

Appendix cont'd

15. How did your mentor help you develop skills to become a department chairman? Rank in order of importance.
    ____ Encouraged research productivity
    ____ Encouraged development of teaching skills
    ____ Introduced me to leaders in the specialty
    ____ Nominated me for membership in societies
    ____ Nominated me as a candidate for chairs
    ____ Gave me administrative responsibilities
    ____ Gave me a budget to manage
    ____ Other
16. Did the national leadership network in obstetrics and gynecology participate in your appointment as chairman?
    Yes ____ No ____
    If yes, how?
    ____ Nominated me as a candidate for chairmanships
    ____ Wrote letters of recommendation and support
    ____ Appointed me to committees of organizations
    ____ Other
17. To which of the following organizations did you belong before becoming department chairman?
    ____ American College of Obstetricians and Gynecologists
    ____ South Atlantic Association of Obstetricians and Gynecologists
    ____ Central Association of Obstetricians and Gynecologists
    ____ Pacific Coast Obstetrical and Gynecological Society
    ____ Society for Gynecologic Investigation
    ____ Association of Professors of Gynecology and Obstetrics
    ____ American Fertility Society
    ____ Society of Perinatal Obstetricians
    ____ Society of Gynecologic Oncologists
    ____ American Gynecological and Obstetrical Society
    ____ Others you consider important (specify) ____
18. Before becoming department chairman, were you an examiner for The American Board of Obstetrics and Gynecology, Inc.?
    Yes ____ No ____
19. On becoming dependent chairman, which of the following qualities, skills, and experiences did you find lacking in yourself that were important for the job as chairman?
    ____ Vision
    ____ Knowledge of the specialty
    ____ Teaching skills
    ____ Research experience
    ____ Communication skills (language fluency)
    ____ Interpersonal skills
    ____ Political awareness
    ____ Social skills
    ____ Administrative skills
    ____ Budget and financial management skills
    ____ Other (specify)
20. How did you overcome these deficiencies? Describe briefly.
21. Do you recommend that a newly appointed department chairman have a short course (2 to 16 weeks) in administration and financial management?
    Yes ____ No ____
    If yes, did you take such a course?
    Yes ____ No ____
22. As department chairman, from whom do you seek advice? Rank in order of importance.
    ____ Former mentor
    ____ Former chairman of your department
    ____ Dean
    ____ Chairman of another department in same medical school
    ____ Another chairman of obstetrics and gynecology
    ____ Senior faculty member in obstetrics and gynecology
    ____ Junior faculty member in obstetrics and gynecology
    ____ Spouse
    ____ Nonphysician friend
    ____ Other
23. Since becoming department chairman, have you become more a part of the national leadership network in obstetrics and gynecology?
    Yes ____ No ____
24. To which of the following organizations have you become a member since becoming department chairman?
    ____ American College of Obstetricians and Gynecologists
    ____ South Atlantic Association of Obstetricians and Gynecologists
    ____ Central Association of Obstetricians and Gynecologists
    ____ Pacific Coast Obstetrical and Gynecological Society
    ____ Society for Gynecologic Investigation
    ____ Association of Professors of Gynecology and Obstetrics
    ____ American Fertility Society

___ Others you consider important (specify) ___

25. Since becoming department chairman, have you become an examiner for The American Board of Obstetrics and Gynecology, Inc.?
Yes ___ No ___

26. In advising a young faculty member to develop leadership qualities, skills, and experiences, which of the following would you emphasize? (Please rank and give order of relative importance: essential, important, or not important.)
Rank
___ Vision
___ Knowledge of specialty
___ Respect within specialty
___ Teaching skills
___ Research experience
___ Communication skills (language fluency)
___ Interpersonal skills
___ Political awareness
___ Social skills
___ Administrative skills
___ Budget and financial management skills
___ Other (specify)

27. Have you become a mentor for a potential leader in obstetrics and gynecology since becoming department chairman?
Yes ___ No ___
If yes, do you (rank in order of importance):
___ Encourage research productivity?
___ Encourage development of teaching skills?
___ Introduce to leaders of specialty?
___ Nominate protegé for membership in societies?
___ Nominate protegé as a candidate for chairs?
___ Give protegé administrative responsibilities?
___ Give protegé budget management responsibilities?
___ Other (specify)

28. Are you grooming a person to become your successor?
Yes ___ No ___
Do you think that person is likely to become a department chairman?
Yes ___ No ___

29. After becoming department chairman, did your medical school provide opportunities to develop leadership skills?
Yes ___ No ___
If yes, how?
___ Association of American Medical Colleges leadership seminars
___ Teaching workshops
___ Management short courses
___ Other (specify)

30. In your opinion, is the traditional academic search committee an effective method for selecting academic department chairmen?
Yes ___ No ___
Briefly explain answer.

Does your school use a search firm to acquire leaders?
Yes ___ No ___

31. Should national organizations of obstetricians and gynecologists develop leadership workshops and seminars for department chairmen and potential future leaders?
Yes ___ No ___
If yes, which of the following organizations could best serve this need?
___ American College of Obstetricians and Gynecologists
___ Association of Professors of Gynecology and Obstetrics
___ American Gynecological and Obstetrical Society
___ Other (specify)

Human ovarian 17-ketosteroid oxidoreductase: Unique characteristics of the granulosa-luteal cell and stromal enzyme

Robert L. Barbieri, MD
Stony Brook, New York

OBJECTIVES: We attempted to test the hypothesis that distinct forms of the 17-ketosteroid oxidoreductase exist in the human ovary and to compare its activity in stroma obtained from normally cycling women and from hyperandrogenic women.
STUDY DESIGN: Human ovarian granulosa-luteal cell and stromal 17-ketosteroid oxidoreductase were examined in cell incubations and subcellular homogenates.
RESULTS: In subcellular homogenates of granulosa-luteal cells 17-ketosteroid oxidoreductase activity was greater in the cytosol fraction than in the membrane fraction. In contrast, in homogenates of both ovarian stroma and Leydig cells its activity was greater in the membrane fraction than in the cytosol fraction. At the substrate concentrations used estrone was a better substrate than androstenedione for the granulosa-luteal cell 17-ketosteroid oxidoreductase. In contrast, androstenedione was a better substrate than estrone for that in ovarian stromal and Leydig cell membranes. In incubations of ovarian stroma from hyperandrogenic women, significantly more testosterone accumulated in the medium per milligram of tissue than in the medium of incubations of ovarian stroma from normally cycling women (142 ± 48 vs 7.9 ± 7.5 pg testosterone per milligram of tissue per 48 hours, mean ± SD, $p < 0.05$). The ratio of testosterone to androstenedione was significantly higher in the medium of incubations of ovarian stroma from hyperandrogenic women than in that from normally cycling women (0.61 vs 0.25, mean, $p < 0.05$). The ratio of serum testosterone to androstenedione was significantly greater in hyperandrogenic women than in normally cycling control women (0.31 ± 0.11 vs 0.20 ± 0.03, mean ± SD, $p < 0.05$).
CONCLUSION: The localization (cytosol fraction) and substrate specificity (estrone) of the granulosa-luteal cell 17-ketosteroid oxidoreductase enzyme resembles that seen in human placenta. The localization (membrane fraction) and substrate specificity (androstenedione) of the ovarian stromal 17-ketosteroid oxidoreductase enzyme resembles that seen in Leydig cells. It may be one enzyme that exists in multiple forms or it may be two (or more) enzymes. In some hyperandrogenic women the ovarian stromal 17-ketosteroid oxidoreductase may be more active than in normally cycling women, contributing to an abnormally increased testosterone production rate. (Am J Obstet Gynecol 1992;166:1117-26.)

Key words: 17-ketosteroid oxidoreductase, granulosa-luteal cell, stromal enzyme

The 17-ketosteroid oxidoreductase enzyme converts the weak androgen androstenedione to the potent androgen testosterone and converts the weak estrogen estrone to the potent estrogen estradiol. The characteristics of the human 17-ketosteroid oxidoreductase enzyme in granulosa-luteal cells, ovarian stroma, and Leydig cells have not been examined in detail. To test the hypothesis that distinct ovarian forms of the 17-ketosteroid oxidoreductase may exist, the substrate specificity and subcellular localization of the enzyme was examined in human granulosa-luteal cells and ovarian stroma. These results were compared with those from Leydig cells. In addition, the activity of ovarian stromal 17-ketosteroid oxidoreductase was compared in stroma obtained from normally cycling women and from hyperandrogenic women.

Material and methods

Granulosa-luteal cell incubations. Granulosa-luteal cells were obtained at the time of oocyte retrieval from women in a program of in vitro fertilization. The granulosa-luteal cells were prepared for incubation as previously described.[1] A 50% Percoll gradient was used to separate the granulosa cells from the red blood cells. Cells were incubated in replicates of four at a cell density of 10,000 cells per well with 1 ml Dulbecco's minimal essential medium without serum at 37° C with 5% carbon dioxide. The well diameter was 16 mm. At the end of a 24-hour incubation period the medium was collected and frozen at −20° C until the steroid assays were performed.

For steroid assay the medium was extracted twice

with 10 volumes of ether. The ether was evaporated under a stream of nitrogen, and the dried steroids were redissolved in isooctane and applied to Celite columns for chromatography. With isooctane and ethyl acetate as the mobile phase, progesterone, androstenedione, dihydrotestosterone, testosterone, estrone, and estradiol were sequentially eluted from the column.[2, 3] Steroids were then measured by radioimmunoassays with specific antibodies. The testosterone antibody had <2% cross reactivity for androstenedione. The androstenedione antibody had <4% cross reactivity for testosterone. The estradiol antibody had <2% cross reactivity for estrone. The estrone antibody had <5% cross reactivity for estradiol. The intraassay and interassay coefficients of variation were <10% and 15%, respectively, for all steroids assayed.

Granulosa-luteal cell fractionation. Granulosa-luteal cells were sonicated for three 10-second bursts at 4° C in 0.01 mol/L phosphate-buffered saline solution. The homogenate was centrifuged at 100,000*g* for 60 minutes. This supernatant was used as the cytosol. The pellet was suspended and homogenized in 0.01 mol/L phosphate-buffered saline solution with a Teflon pestle and glass vessel and used as the membrane fraction.

Measurement of 17-ketosteroid oxidoreductase activity in granulosa-luteal cell fractions. The assay for the 17-ketosteroid oxidoreductase used a reaction mixture containing 0.15 mol/L sodium chloride and 0.01 mol/L phosphate at pH 7.4 and 37° C, 2 mg/ml bovine serum albumin, 500 μmol/L reduced nicotinamide adenine dinucleotide phosphate, 50 mmol/L glucose-6-phosphate, 2 U of glucose-6-phosphate dehydrogenase, and appropriate concentrations of tritiated steroid and unlabeled steroid precursor (androstenedione or estrone) in a final volume of 0.4 ml.[2]

Three concentrations of substrate (estrone or androstenedione) were used: 25, 200, and 500 nmol/L. The protein concentration was 140 μg for the membrane fraction and 106 μg for the cytosol fraction per incubation. The incubation times were 3 and 12 minutes. Duplicate incubations were performed at each time point. To inhibit aromatase, 20 μmol/L aminoglutethimide was added to all incubations. The reaction was terminated by adding 0.4 ml methanol. The assay was linear with the time and protein content.[2] Steroids were extracted with ether and separated by Celite chromatography.

Incubations of human ovarian stroma. Ovarian tissue was obtained from seven hyperandrogenic and six nonhyperandrogenic women undergoing oophorectomy or ovarian cystectomy. All were in the follicular phase of the menstrual cycle. Stromal tissue was prepared from the ovarian specimens as previously described.[3] With a dissecting microscope the tunica albicans was stripped from the specimens, and all follicles >1.0 mm in diameter were dissected free of the stromal tissue. The stromal tissue was dissected into pieces <1.5 mm in maximum diameter. The minced stroma was washed twice in Dulbecco's minimal essential medium and randomly aliquoted to culture wells in a 24-well plate. Incubations were performed for 48 hours in quadruplicate in plastic culture wells with 1 ml Dulbecco's minimal essential medium with glutamine, penicillin, and streptomycin at 37° C in 5% carbon dioxide with air. At the termination of the 48-hour incubation the media were frozen at −20° C until steroid assays were performed.[2, 3] Differences in steroid accumulation in the incubation medium between hyperandrogenic and normal ovarian specimens were evaluated with both the *t* test and Wilcoxon rank sum test. Differences in the testosterone-to-androstenedione ratio were evaluated with the Wilcoxon rank sum test.

Measurement of 17-ketosteroid oxidoreductase activity in ovarian stroma fractions. Stroma was prepared from whole ovaries as noted above. The stroma was homogenized in a Brinkman system with 0.01 mol/L phosphate-buffered saline solution. The homogenate was sonicated with three 10-second pulses at 4° C. The sonicated homogenate was centrifuged for 10 minutes at 100*g* and the pellet was discarded. The supernatant was centrifuged at 100,000*g* for 60 minutes. This supernatant was used as the cytosol fraction. The pellet from the 100,000*g* centrifugation step was homogenized in 0.01 mol/L phosphate-buffered saline solution and used as the membrane fraction.

The assay for the 17-ketosteroid oxidoreductase was similar to that for the granulosa-luteal cells. Three concentrations of substrate were used: 200 nmol/L, 500 nmol/L, and 1 μmol/L.

Measurement of 17-ketosteroid oxidoreductase activity in Leydig cell fractions. Testes were obtained from orchiectomy specimens. Leydig cells were prepared as previously described.[2] The Leydig cells were disrupted by sonication with three 10-second pulses. The sonicate was centrifuged at 100,000*g* for 60 minutes. The supernatant was used as the cytosol fraction. The pellet was homogenized and used as the membrane fraction. The assay for the 17-ketosteroid oxidoreductase was similar to that for the granulosa-luteal cells. Two concentrations of substrate were used: 200 and 500 nmol/L.

Testosterone-to-androstenedione ratio in women. Serum testosterone, androstenedione, and progesterone were measured with ether extraction, Celite chromatography, and specific radioimmunoassays in 7 normally cycling women and 11 hyperandrogenic women.[2, 3] None of these women contributed ovarian specimens to the studies of ovarian stroma (see above). The normally cycling women were nonhirsute and had menstrual cycle lengths between 27 and 32 days. The

Androstenedione	Testosterone	Membrane	—	1.8	3.5

Each value represents the mean of two incubations (picomoles per minute per milligram of protein).

11 hyperandrogenic women were oligomenorrheic and hirsute and had at least one elevated total testosterone concentration before entry into this study. Serum was obtained between 8 and 9 AM. All women were studied in the follicular phase of the menstrual cycle, as determined by a progesterone concentration <2 ng/ml. Non–sex hormone–binding globulin–bound testosterone was determined with an ammonium sulfate precipitation technique at 4° C.[4] Differences in the serum androstenedione and testosterone concentration between the hyperandrogenic and normally cycling women were evaluated with the *t* test. Differences in the ratio of testosterone to androstenedione and non–sex hormone–binding globulin–bound testosterone to androstenedione in the hyperandrogenic and normally cycling women were evaluated with the Wilcoxon rank sum test.

For all studies protein concentrations were determined by the method of Bradford.[5] Tritium-labeled steroids were obtained from Dupont (Boston) and purified by high-performance liquid chromatography on a C-18 micro-Bondapak column (Millipore, Bedford, Mass.) before use. Collagenase was obtained from Worthington Biochemical Co. (Freehold, N.J.). All other reagents were obtained from Sigma Chemical Co. (St. Louis).

Results

Granulosa-luteal cell incubations. In serum- and lipid-free medium, progesterone accumulated (22,000 ± 4500 pg/ml, mean ± SD) in the medium, but androstenedione, testosterone, dihydrotestosterone, estrone, and estradiol were not detected (<10 pg/ml). The addition of androstenedione to the medium resulted in a concentration-dependent increase in estradiol release into the medium over a range of androstenedione from 5 to 1000 nmol/L. Addition of 10,000 pg/ml androstenedione at time 0 to 10,000 granulosa cells resulted in the appearance of 506 ± 60 pg/ml estradiol, <40 pg/ml estrone, and <40 pg/ml testosterone in the medium at 24 hours of culture.

Addition of 1 μCi of tritiated progesterone or tritiated estradiol to 10,000 granulosa cells for 24 hours resulted in the conversion of <10% of the progesterone and <5% of the estradiol to other metabolites, as determined by high-performance liquid chromatography (C18-Bondapek, methanol-water liquid phase).

Localization and substrate specificity of 17-ketosteroid oxidoreductase activity in homogenates of granulosa-luteal cells. As noted in Table I, both the cytosol and the membrane fraction contained measurable enzyme activity with both estrone and androstenedione as substrates. At the substrate concentrations used, the majority of enzyme activity was localized to the cytosol fraction. In the cytosolic and membrane fraction, product formation was greater when estrone was used as the substrate than when androstenedione was used. At the substrate concentrations used, a maximal velocity was not achieved.

Incubations of human ovarian stroma. At time zero, stromal tissue contained <5 pg/mg tissue of androstenedione, testosterone, and progesterone and <1 pg/mg tissue of dihydrotestosterone, estrone, and estradiol. For all ovarian specimens, after 48 hours of incubation, testosterone and androstenedione concentrations in the medium were greater than that present in tissue at time 0 (Table II). The ovarian stroma from the hyperandrogenic women released significantly more testosterone into the medium over 48 hours of incubation than stroma from the nonhyperandrogenic women. The amount of androstenedione released into the medium was not statistically different between the two groups, in part because of the large variance observed in androstenedione accumulation among specimens. In the incubations of stroma from the nonhyperandrogenic women, 4.0 molecules of androstenedione accumulated in the media for each molecule of testosterone. In contrast, in the incubations of stroma from the hyperandrogenic women, 1.6 molecules of androstenedione accumulated in the media for each molecule of testosterone. The ratio of testosterone to androstenedione released into the medium was significantly higher in the incubations of stroma from hyperandrogenic women ($p < 0.05$).

Localization and substrate specificity of 17-ketosteroid oxidoreductase activity in homogenates of

Table II. Accumulation of androstenedione and testosterone in the medium of incubations of ovarian stroma from normally cycling women and hyperandrogenic women

Table III. Distribution of 17-ketosteroid oxidoreductase in homogenates of ovarian stroma with estrone and androstenedione used as substrates

Substrate	*Product*	*Cell fraction*	*Substrate concentration*		
			200 nmol/L	*500 nmol/L*	*1 μmol/L*
Estrone	Estradiol	Cytosol	0.55	1.9	2.2
Androstenedione	Testosterone	Cytosol	0.54	1.3	3.3
Estrone	Estradiol	Membrane	1.8	8.1	5.3
Androstenedione	Testosterone	Membrane	3.3	9.1	15.8

Each value represents the mean of two incubations (picomoles per minute per milligram of protein).

ovarian stroma. Using stroma from a premenopausal ovary, 17-ketosteroid oxidoreductase activity was detected in both cytosolic and membrane fractions (Table III). At the substrate concentrations used, the majority of enzyme activity was in the membrane fraction when estrone or androstenedione was used as substrates. In the cytosolic fraction the amount of product formed was similar when estrone or androstenedione was used as substrate. In the membrane fraction, at substrate concentrations of 200 nmol/L and 1 μmol/L more product formation was observed when androstenedione was used as substrate than when estrone was used. In the data presented in Table III, 500 nmol/L estrone resulted in greater product formation than did 1 μmol/L estrone. This anomaly could be explained by experimental variability or a technical error. At the substrate concentrations used, a maximal velocity was not achieved. In an additional ovarian specimen from a premenopausal woman, when androstenedione was used as the substrate, 88% of the enzyme activity was in the membrane fraction and 12% of the activity was in the cytosol fraction. In an ovarian specimen from a menopausal woman, when androstenedione was used as the substrate, 100% of the enzyme activity was in the membrane fraction. No activity could be detected in the cytosolic fraction.

Localization and substrate specificity of 17-ketosteroid oxidoreductase activity in homogenates of Leydig cells. Enzyme activity was detected in the cytosol and membrane fractions of Leydig cells (Table IV). At the substrate concentrations used, the majority of activity was in the membrane fraction when estrone or androstenedione was used as substrate. In the membrane fraction at both substrate concentrations tested, more product was formed when androstenedione was used as substrate than when estrone was used.

Testosterone-to-androstenedione ratio in women. Serum androstenedione, total testosterone, and non–sex hormone–binding globulin–bound testosterone were significantly higher in the hyperandrogenic women than in the normally cycling control women (Table V). In comparing the two groups, androstenedione, testosterone, and non–sex hormone–binding globulin–bound testosterone were 104%, 217%, and 570% higher, respectively, in the hyperandrogenic women ($p < 0.05$) than in the control women. The testosterone-to-androstenedione ratio was 55% higher in the hyperandrogenic women than in the controls ($p < 0.05$). The non–sex hormone–binding globulin–bound testosterone-to-androstenedione ratio was 221% higher in the hyperandrogenic women than in the controls ($p < 0.05$).

Comment

Since the description by Ryan and Engel[6] of the interconversion of estrone and estradiol by human tissue slices, many investigators have proposed that human 17-ketosteroid oxidoreductase activity (also referred to as 17β-hydroxysteroid dehydrogenase, EC 1.1.1. 62) is composed of one enzyme that exists in multiple forms or is actually two or more enzymes.[7, 8] For example, Tseng et al.[7] reported that an antiserum

raised against human placental estradiol lehydroge-nase could inhibit placental 17-ketostero oxidored-uctase activity but could not inhibit end netrial 17-ketosteroid activity. They concluded that cental and endometrial forms of 17-ketosteroid ox oreductase were immunologically distinct proteins. omquist et al.[8] reported that human placenta may co in two distinct forms of 17-ketosteroid oxidoreducta One form recognized C_{18}-, C_{19}-, and C_{20}-steroids with omparable affinities, and this activity could be comple y inhibited by dihydrotestosterone. The second form f 17-keto-steroid oxidoreductase was highly specific estradiol, and this activity could only be partially hibited by dihydrotestosterone.

Evidence that the protein(s) responsibl for 17-ketosteroid oxidoreductase activity exists multiple physicochemical forms is provided by the bservation that 17-ketosteroid oxidoreductase activity s predominantly in the cytosolic fraction of some ti ues and is predominantly in the membrane fraction other tissues. Tissues and cells where the 17-keto eroid oxidoreductase activity is predominatly in t cytosolic fraction of homogenized tissue or cells inc de human placenta,[9] whole human ovary,[10] ovine ova ,[11] and rat granulosa cells.[2] In contrast, tissues and cel where the 17-ketosteroid oxidoreductase activity is predominantly in the membrane fraction of homogenized tissues and cells include the human endometrium,[7] rat testis,[12] canine testis,[13] porcine testis,[14] hamster testis,[15] and rat Leydig cells.[2] It is likely that the 17-ketosteroid oxidoreductase protein present in the cytosol of ovary and placenta is more hydrophilic than that present in the membrane fraction of testis and endometrium.

In the current study the majority of 17-ketosteroid oxidoreductase activity was present in the cytosolic fraction of granulosa-luteal cell homogenates regardless of whether estrone or androstenedione was used as the substrate. In homogenates of granulosa-luteal cells, 84% of the 17-ketosteroid oxidoreductase activity was in the cytosolic fraction at an estrone concentration of 500 nmol/L. In contrast, in homogenates of Leydig cells, the majority of the 17-ketosteroid oxidoreductase activity was in the membrane fraction whether estrone or androstenedione was used as the substrate. In homogenates of Leydig cells 99% of the 17-ketosteroid oxidoreductase activity was in the membrane fraction at androstenedione concentrations of 500 nmol/L. The ovarian stroma resembled the Leydig cell in that the majority of the 17-ketosteroid oxidoreductase activity was in the membrane fraction of the homogenate whether estrone or androstenedione was used as the substrate. In the human ovarian stroma 83% of the 17-

ketosteroid oxidoreductase activity was in the membrane fraction at the androstenedione concentration of 1 μmol/L. An important caveat is that the ovarian stroma is a complex tissue with blood vessels, lymphatics, nerves, small follicles containing granulosa cells and theca, and ovarian mesenchymal cells. The contribution of each of these cell types to the stromal 17-ketosteroid oxidoreductase activity is unknown. In one study of a postmenopausal ovary (no follicles), the 17-ketosteroid oxidoreductase activity was localized to the membrane fraction, suggesting that the small follicles present in the premenopausal ovarian stroma do not contain all of the stromal 17-ketosteroid oxidoreductase activity. At the substrate concentrations used, a maximal velocity was not achieved. Future studies will be required to determine the Michaelis-Menten constants and the maximal velocities for these enzymes.

Additional evidence that the protein(s) responsible for 17-ketosteroid oxidoreductase activity exists in multiple forms is provided by the observation that the rat granulosa cell and Leydig cell 17-ketosteroid oxidoreductase have different substrate specificities.[2] In the intact rat granulosa cell and in rat granulosa cell cytosol, estrone is a preferred substrate to androstenedione.[2] In contrast, in the intact rat Leydig cell and in rat Leydig cell microsomes, androstenedione is a preferred substrate to estrone.[2] In the current study in granulosa-luteal cell cytosol product formation was greater when estrone was used as a substrate than when androstenedione was used. In the ovarian stroma membrane preparation, at two substrate concentrations (200 nmol/L, 1 μmol/L), more product formation was observed when androstenedione was used as a substrate than when estrone was used. At a third substrate concentration, (500 nmol/L), product formation was similar with both substrates. Further information will be necessary to clarify the substrate specificities of the 17-ketosteroid oxidoreductase in human granulosa-luteal cells and ovarian stroma.

Recently, two genes for human 17-ketosteroid oxidoreductase have been cloned and sequenced and assigned to chromosome 17q12.[16-18] These two genes are in tandem and contain 89% homology in the overlapping exons and introns. The gene h17-β-hydroxysteroid dehydrogenase II encodes a protein of approximately 327 amino acids with a predicted molecular weight of 34,853.[17] The gene h17-β-hydroxysteroid dehydrogenase I may encode for a protein of approximately 214 amino acids, or it may be a pseudogene.[18] Of particular interest, the human placenta contains two messenger ribonucleic acid species for the 17-ketosteroid, a major species migrating at 1.3 kb and a minor species migrating at 2.2 kb.[17] The 1.3 kb species is also predominant in some human ovarian specimens.[18] The 2.2 kb species is predominat in endometrium, myometrium, uterus, breast, prostate, and fat tissue.[18]

Incubation of the granulosa-luteal cells in serum-free medium resulted in the accumulation of progesterone in the range of 2 pg per cell per 24 hours. Androstenedione, testosterone, estrone, and estradiol could not be detected in the medium. Addition of androstenedione to the medium resulted in the dose-dependent accumulation of estradiol, with minimal accumulation of estrone or testosterone. This finding of a low testosterone-to-androstenedione ratio but high estradiol-to-estrone ratio has also been reported by McNatty et al.[19] in human follicular fluid. In follicular fluid from healthy follicles, the steroid concentrations were androstenedione 930 ng/ml, testosterone 63 ng/ml, estrone 62 ng/ml, and estradiol 465 ng/ml.[19] This results in a testosterone-to-androstenedione ratio of 0.07 and an estradiol-to-estrone ratio of 7.5. The differences in the ratios of the 17-hydroxy to 17-keto forms of these two steroid pairs remains to be fully explained. The biologic effect is to allow for the accumulation of large amounts of the potent estrogen estradiol and minimal amounts of the potent androgen testosterone.

The incubations of ovarian stroma from normally cycling women resulted in the accumulation of testosterone and androstenedione in a ratio of 0.25 (testosterone to androstenedione). This is similar to the testosterone-to-androstenedione ratio observed by McNatty et al.[20,21] in incubations of human ovarian theca (0.04 to 0.13) and stroma (0.26 to 0.42) from normally cycling women. In the incubations of ovarian stroma from the hyperandrogenic women, significantly more testosterone accumulated and the testosterone-to-androstenedione ratio was significantly greater than that observed in the normally cycling women (0.61 vs 0.25, $p < 0.05$). These results suggest that one mechanism subserving the development of ovarian hyperandrogenism is an increase in stromal 17-ketosteroid oxidoreductase, resulting in an abnormally elevated testosterone-to-androstenedione ratio. McNatty et al.[21] studied the ovarian tissue of a woman with the syndrome of hyperandrogenism-insulin resistance and acanthosis nigricans.[22] This woman had a point mutation in both alleles of the insulin receptor gene, resulting in a nonfunctional insulin receptor because of the replacement of a valine for a phenylalanine at amino acid 382.[23] In incubations of ovarian stroma from this woman the testosterone-to-androstenedione ratio ranged from 3.94 to 20.5. This markedly abnormal ratio in the presence of a severely hyperinsulinemic state suggests that hyperinsulinemia may contribute to the stimulation of stromal 17-ketosteroid oxidoreductase activity.

If one mechanism subserving the development of ovarian hyperandrogenism is an increase in ovarian stromal 17-ketosteroid oxidoreductase, then women with hyperandrogenism may have an abnormal ratio of testosterone to androstenedione in the circulation.

The normally cycling women in this study had a serum testosterone-to-androstenedione ratio of 0.20. This is similar to that observed in normally cycling women by Aiman et al.[24] (0.19) and Chang et al.[25] (0.20). In this study the ratio of serum testosterone to androstenedione was significantly elevated in hyperandrogenic women compared with normally cycling controls (0.31 ± 0.11 vs 0.20 ± 0.03, $p < 0.05$). In future studies the measurement of the serum testosterone-to-androstenedione ratio in normal and hyperandrogenic women after adrenal suppression is planned to evaluate the ovarian and adrenal contributions to this finding.

In this study evidence has been presented that human ovarian stroma and granulosa-luteal cells may contain different forms of the 17-ketosteroid oxidoreductase enzyme. The ovarian stromal 17-ketosteroid oxidoreductase resembles the enzyme present in Leydig cells, and the granulosa-luteal cell 17-ketosteroid oxidoreductase resembles the enzyme present in the placenta. In some hyperandrogenic women, the ovarian stromal 17-ketosteroid oxidoreductase may be overexpressed, contributing to an abnormally increased testosterone production rate.

Editors' note: This manuscript was revised after these discussions were presented.

Discussion

Dr. Howard C. Judd, (Fellow) Los Angeles, California. This study represents a comprehensive attempt to define the 17-ketosteroid oxidoreductase enzyme with both in vitro and in vivo methods. It falls into four basic studies. First, enzyme activity was localized to specific subcellular sites and was quantitated in granulosa-luteal cells obatined from patients undergoing ovarian hyperstimulation for in vitro fertilization. Second, similar experiments were performed with cells from the ovarian stroma obtained at surgery from normal and hyperandrogenized women. Third, the same experiments were performed on Leydig cells obtained after

orchiectomy. And, finally, enzyme activity was assessed indirectly by measurement of serum levels of androstenedione, testosterone, and non–sex hormone–binding globulin–bound testosterone obtained from normal and hyperandrogenized women.

In general, the methods used in this study were reasonably sophisticated, the statistical approach to the analyses of data was appropriate, the presentation of the results was clear, and the interpretation of the results was restrained and cautious. Thus Dr. Barbieri should be commended for his efforts. It should also be pointed out that Dr. Barbieri is a sophisticated reproductive endocrinologist and as such knows that studies of this nature are always open to criticism and concern. Thus his judicious and careful interpretation of his finding is to be complimented.

In critiquing Dr. Barbieri's study, I would like to address three issues. My task in being the official reviewer is to offer some criticisms. This critique should not be taken by anyone to indicate I disapprove of it, which I do not. The first is the possible error that could occur with metabolism of either substrate or product hormone. Dr. Barbieri quantitated enzymatic activity by exposing whole cells or cell fractions to substrate hormone and measuring product hormone by radioimmunoassay. As long as the metabolism of the substrate hormones androstenedione and estrone or the product hormones testosterone and estradiol was the same, then this type of comparison was reasonable. If it was not, then problems could exist. For example, 5α-reduction of androstenedione and testosterone is known to occur but can't with estrone and estradiol. Could 5α-reduction of these androgens influence the current findings? It would appear that, with the exception of granulosa-luteal cell studies, no assessment of metabolism of androgens other than 17-ketosteroid oxidoreductase was made. How much does Dr. Barbieri think other metabolism of these androgens influenced his results?

Second, Dr. Barbieri is careful to point out that the maximum velocity of this enzyme was not assessed in any of these experiments. This is too bad because maximum velocity is a constant for any enzyme that allows for comparisons between tissue or cell fragments. If maximum velocity is not measured, then interpretation of data is problematic. Incubation conditions can influence findings leading to potential errors of interpretation. We look forward to Dr. Barbieri's future studies of maximum velocity, which hopefully will confirm the present results.

Last, Dr. Barbieri has estimated 17-ketosteroid oxidoreductase activity indirectly by measuring the ratios of testosterone to androstenedione and non–sex hormone–binding globulin–bound testosterone to androstenedione in the circulation of normal and hyperandrogenized women. This type of comparison would be reasonable if the metabolic clearance rates of androstenedione and testosterone were similar in normal and hyperandrogenized women.[1] For androstenedione this is the case, but for testosterone there is usually a twofold increase of its metabolic clearance rate in hyperandrogenized women as compared with normal women. Dr. Barbieri did not measure the metabolic clearance rate of testosterone or use historic data to control for this potential artifact. This deficit is partially accounted for by measuring non–sex hormone–binding globulin–bound testosterone levels but not completely. Thus the difference in the ratios of circulating testosterone or non–sex hormone–binding globulin–bound testosterone to androstenedione probably underestimates the actual activity of this enzyme to form testosterone in vivo.

Although as yet it is not definitive, this article represents a considerable amount of work. The methods used show an admirable degree of sophistication and the restraint exercised in interpreting the results demonstrate a clear understanding of the limits of this study.

Dr. Robert B. Jaffe, San Francisco, California. As always, Dr. Barbieri has given an extremely lucid and thoughtful presentation of a large amount of data. I would suggest that to localize the enzyme, when the probes for either of the two forms that he listed on the board become available to him or when the expressed protein from these genes becomes available, he consider using either in situ hybridization with the former or immunocytochemical localization with the latter as a much better way to determine precisely where the enzymes are located.

This is particularly true for his luteinizing granulosa cells because these represent a very diverse group of cells. I suspect it might be better if you were to use intact ovarian tissue with in situ hybridization or immunocytochemical localization as a better way to get at the site of production of these enzymes.

Dr. Edward E. Wallach, Baltimore, Maryland. Since the ovarian stroma merges with the theca cells surrounding the follicle and the theca cells are responsible for production of androstenedione as a precursor or substrate for estradiol specifically in the preovulatory phase of the cycle, I wonder if you would comment on whether the ratio described may be dependent, in either the hyperandrogenic women or the nonhyperandrogenic women, on the phase of the cycle in which the stromal tissue was obtained.

Dr. Georgeanna S. Jones, Norfolk, Virginia. I was particularly interested in the location of the androgenic and the estrogenic enzyme. It seems to me that in the normal situation of these enzymes may allow us to understand how under abnormal conditions we see an apparent incongruous elevation of luteinizing hormone.

Dr. M. Yusoff Dawood, Houston, Texas. Dr. Barbieri, could you tell us how you calculated your non–

sex hormone–binding globulin–binding globulin? What method did you use? Have you had a chance to examine this enzyme in either corpus luteum or ovarian tissues in women treated with gonadotropin-releasing hormone agonists or oral contraceptives?

Dr. James M. Roberts, San Francisco, California. I have two questions. One is related to the affinity of the enzyme. A linear increase in production of hormone going from 200 mol/L to 500 mol/L in the animal would imply the Michaelis-Menten coefficient is probably 10 times higher. Is that a reasonable value for this enzyme?

Second, as an extension of Dr. Jaffe's comment and perhaps a way you can get more information out of the data you've generated, I'm concerned about expressing enzyme activities per milligram protein in cytosol and membrane when you have different size cells, and I wonder, if you looked at total activity per cell, by coming up with some estimate on how many total milligrams of protein are in the membranes from cells and how many total milligrams of protein are in cytosol, whether the differences would still maintain.

Dr. W. Leroy Heinrichs, Stanford, California. It's an important study; this ubiquitous enzyme seems, however, at least in the endometrium to be regulated by progesterone. You've chosen as your two patient groups normally cycling women and hyperandrogenic women, the latter unlikely to be ovulating and therefore with lesser concentrations of progesterone in the circulation.

My questions are, have you evaluated your enzyme in terms of the progesterone environment in the preovulatory-postovulatory portions of the cycles of normal women and what are the progesterone concentrations in the tissue or plasma of women who are hyperandrogenic?

Dr. Donald Pittaway, Winston-Salem, North Carolina. One difficulty I see is when one looks at the ovarian venous data in such women. In general, the testosterone-to-androstenedione ratios are actually decreased in the androgenic women. Certainly there are exceptions to this. The majority of women actually have a reduced ratio in the ovarian veins, indicating a less efficient glandular conversion of androstenedione to testosterone. I wonder if you would comment on this.

Dr. Norman F. Gant, Dallas, Texas. I believe that Roberts asked one of the key questions and that was what was the specific activity per cell? If we're talking about hyperandrogenism, are we talking about more cells, bigger cells or both? How long have these cells been "banged away at" by luteinizing hormone? The key issue is whether the specific activity of this enzyme is increased or whether there are more or larger cells.

Dr. Frederick Naftolin, New Haven, Connecticut. In support of Dr. Barbieri's work, we've used such a probe as Dr. Jaffe suggests. We have an antiserum grown from Lou Engle's oxidoreductase 20 years ago. In fact, what we find is that there is a scattered patchiness in the stroma that registers immunopositive for this enzyme. There are, in fact, two enzymes, and our antiserum only recognizes the one that's in the placenta and not the one, for example, in the uterus.

I would say that it would be very helpful for you to use such an antiserum as a control on the dissections you use to get the stroma, because I believe many of the questions that we're asking relate to the differences within the stroma in the ability of this enzyme to be expressed.

Dr. Barbieri (Closing). I would like to thank Dr. Judd for his thorough review of my manuscript. Because of time constraints, I was unable to mention that the work of Dr. Judd played an important role in the development of my ideas concerning 17-ketosteroid oxidoreductase.

In menopausal women the ovary consists mainly of ovarian stroma. Dr. Judd has demonstrated that the main steroid secreted by the menopausal ovary is testosterone. I believe that in the menopause high luteinizing hormone levels activate stromal 17-ketosteroid oxidoreductase, causing an increased conversion of androstenedione to testosterone. As in the menopausal women, the high luteinizing hormone concentration present in hyperandrogenic women may cause an activation of ovarian stromal 17-ketosteroid oxidoreductase.

I would like to also say that this article in no way represents the final data concerning this subject. I see science as a cumulative process, and my goal with this article was to stimulate other researchers to try to describe in greater detail the microheterogeneity that might exist with regard to ovarian 17-ketosteroid oxidoreductase.

Dr. Judd raises an important point concerning the alternative pathways for metabolism of androstenedione, testosterone, estrone, and estradiol in our laboratory studies. In the granulosa cells we incubated radioactive estradiol and radioactive progesterone with the cells for 24 hours and then evaluated the radioactive metabolites with high-performance liquid chromatography. In the human granulosa-luteal cells, very little of the added estradiol or progesterone was metabolized to other identifiable metabolites. In the ovarian stroma, our analysis of possible routes of metabolism for androstenedione and testosterone was more limited. We did analyze tissue for the presence of androsterone and androstanediol and were unable to detect significant amounts of these metabolites in the medium of incubation of ovarian stroma. Small amounts of dihydrotestosterone, <5 pg/mg wet weight of tissue per 48 hours, did accumulate in the media. So this is an important concern that would need further analysis.

Another question by Dr. Judd concerns the determination of the maximum velocity and Michaelis-Menten coefficient. It's very difficult to obtain enough human tissues for 17-ketosteroid oxidoreductase to perform these studies. In the laboratory I prefer to work with rat tissues rather than human tissues because of tissue availability. Previous work in our laboratory, in conjunction with Dr. Ryan, has demonstrated that there appears to be preferential affinity of the rat gran-

ulosa cell 17-ketosteroid oxidoreductase for estrone and preferential affinity of the rat Leydig cell 17-ketosteroid oxidoreductase for androstenedione; and in those articles we did publish detailed maximum velocity and Michaelis-Menten coefficient values.

The third point by Dr. Judd was that in hyperandrogenic women there is an increased metabolic clearance rate of testosterone, and I agree with him that this would tend to produce an error of underestimation of the ratio of serum testosterone to androstenedione. Our data suggest that the ratio of serum testosterone to androstenedione is increased in our population of hyperandrogenic women compared with controls. Dr. Jaffe mentioned using immunocytochemical techniques to look at the localization of the 17-ketosteroid oxidoreductase enzyme, and I agree that needs to be performed at a future date.

Dr. Wallach questioned the effects of cycle phase on 17-ketosteroid oxidoreductase, and we have no data concerning the effects of progesterone, or cycle phase, on either granulosa cell or stromal 17-ketosteroid oxidoreductase. Of interest, as he mentioned, the theca provides a substantial amount of androstenedione for aromatization by the granulosa cells to estrone. A characteristic feature of follicular fluid is that there is a very high ratio of estradiol to estrone, but the ratio of testosterone to androstenedione is very, very low. So the androstenedione is present in high concentrations, and estradiol is present in high concentrations but not testosterone.

Dr. Jones mentioned the possibility that activation of 17-ketosteroid oxidoreductase may play a role in the control of luteinizing hormone levels in women with hyperandrogenism, and I think this deserves further exploration.

A question was raised concerning our ammonium sulfate precipitation technique for determining non–sex hormone–binding globulin–bound testosterone levels. Sex hormone–binding globulin affinity for testosterone is temperature dependent. The typical ammonium sulfate assays are performed at 4° C, which produces an incorrect assessment of the true non–sex hormone–binding globulin–bound testosterone that actually occurs at 37° C. However, the ammonium sulfate technique is easy to perform and has a low intraassay and interassay coefficient of variation. We calculated the amount of radioactive testosterone bound to the globulin fraction of the ammonium sulfate fractionation and the amount that was in the nonglobulin fraction. These percentages were then multiplied by the total testosterone concentration to arrive at a non–sex hormone–binding globulin–bound testosterone and sex hormone–binding globulin–bound testosterone concentrations.

In the corpus luteum 17-ketosteroid oxidoreductase is probably in the cytosol. I believe Dr. Pittaway has published previous reports on the occurrence of corpus luteum 17-ketosteroid oxidoreductase in the cytosol.

Dr. Roberts raises the question of the Michaelis-Menten coefficient. I believe that the Michaelis-Menten coefficient for the 17-ketosteroid oxidoreductase with estrone used as a substrate and the enzyme derived from the granulosa cell or placenta is in the range of approximately 1 to 4 μmol/L. We chose subtrate concentrations slightly below this because we believe this is the concentration of substrate that exists in the ovary in the in vivo state.

Dr. Roberts and Dr. Gant raised the issue of activity per whole cell. I think in some way the hyperthyroidism situation is analogous to the situation of hyperandrogenism. In hyperthyroidism the thyroid overproduces thyroxine and triiodothyronine, but the degree of overproduction of triiodothyronine is much greater than the degree of overproduction of thyroxine. So the thyroid becomes more efficient in producing the biologically potent thyroid hormone. In a like manner, in the hyperandrogenic ovary there is a dramatic increase in both androstenedione and testosterone production, but, especially in women with ovarian stromal hyperthecosis, the increase in testosterone production is disproportionately greater than the increase in androstenedione production.

Dr. Heinrichs raised the issue of endometrial 17-ketosteroid oxidoreductase being regulated by progesterone. I think this nice example of regulation of an enzyme by progesterone suggests that the upstream region from 17-ketosteroid oxidoreductase should be cloned, and the regulation of this gene should be looked at in greater detail. A progesterone hormone response element is probably present upstream of the 17-ketosteroid oxidoreductase gene.

The serum concentration of testosterone and androstenedione were measured in the follicular phase. The progesterone concentrations in hyperandrogenic and control women were <3 ng/ml.

A PILL WITH A PROGRAM

Only TRI-NORINYL starts your OC patients with The TRI-NORINYL Total Health Program.™

When you start your OC patient with The TRI-NORINYL Total Health Program sample package, you provide the benefits of oral contraception *plus* an exciting new patient-support program.

The TRI-NORINYL Total Health Program sample package contains one cycle of TRI-NORINYL; the attractive Wallette® Pill Dispenser; and a patient Q&A booklet—*plus* the video and instruction guide, *The ACOG Balanced Fitness Workout;* and program membership. The TRI-NORINYL Total Health Program provides a variety of fitness and health information to help women achieve healthier lifestyles.

As part of that goal, Syntex Laboratories is proud to be a sponsor of the American Medical Association's Women's Health Campaign.

For details about The TRI-NORINYL Total Health Program, please contact your Syntex Representative.

Serious as well as minor side effects have been reported following the use of oral contraceptives. These include thrombo-embolic disease.

Please see adjacent page for brief summary of prescribing information.

TRI-NORINYL TABLETS

(NORETHINDRONE AND ETHINYL ESTRADIOL)

ORAL CONTRACEPTIVE AGENTS: BRIEF SUMMARY

DESCRIPTION

TRI-NORINYL 21-DAY Tablets provide an oral contraceptive regimen of 7 blue tablets followed by 9 yellow-green tablets and 5 more blue tablets. Each blue tablet contains norethindrone 0.5 mg and ethinyl estradiol 0.035 mg and each yellow-green tablet contains norethindrone 1 mg and ethinyl estradiol 0.035 mg.

TRI-NORINYL 28-DAY Tablets provide a continuous oral contraceptive regimen of 7 blue tablets, 9 yellow-green tablets, 5 more blue tablets, and then 7 orange tablets. Each blue tablet contains norethindrone 0.5 mg and ethinyl estradiol 0.035 mg, each yellow-green tablet contains norethindrone 1 mg and ethinyl estradiol 0.035 mg, and each orange tablet contains inert ingredients.

INDICATIONS AND USAGE

Oral contraceptives are indicated for the prevention of pregnancy in women who elect to use these products as a method of contraception.

CONTRAINDICATIONS

Oral contraceptives should not be used in women who have the following conditions: Thrombophlebitis or thromboembolic disorders • A past history of deep vein thrombophlebitis or thromboembolic disorders • Cerebral vascular or coronary artery disease • Known or suspected carcinoma of the breast • Carcinoma of the endometrium, and known or suspected estrogen-dependent neoplasia • Undiagnosed abnormal genital bleeding • Cholestatic jaundice of pregnancy or jaundice with prior pill use • Hepatic adenomas, carcinomas or benign liver tumors • Known or suspected pregnancy

WARNINGS

Cigarette smoking increases the risk of serious cardiovascular side effects from oral contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia and gallbladder disease, although the risk of serious morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemias, hypercholesterolemia, obesity and diabetes.

Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks.

The information contained in this package insert is principally based on studies carried out in patients who used oral contraceptives with formulations containing 0.05 mg or higher of estrogen. The effects of long-term use with lower dose formulations of both estrogens and progestogens remain to be determined.

Throughout this labeling, epidemiological studies reported are of two types: retrospective or case control studies and prospective or cohort studies. Case control studies provide a measure of the relative risk of a disease. Relative risk, the *ratio* of the incidence of a disease among oral contraceptive users to that among non-users, cannot be assessed directly from case control studies, but the odds ratio obtained is a measure of relative risk. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide not only a measure of the relative risk but a measure of attributable risk, which is the *difference* in the incidence of disease between oral contraceptive users and non-users. The attributable risk does provide information about the actual occurrence of a disease in the population.

1. THROMBOEMBOLIC DISORDERS AND OTHER VASCULAR PROBLEMS

a. Myocardial infarction

An increased risk of myocardial infarction has been attributed to oral contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary artery disease such as hypertension, hypercholesterolemia, morbid obesity and diabetes. The relative risk of heart attack for current oral contraceptive users has been estimated to be 2 to 6. The risk is very low under the age of 30. However, there is the possibility of a risk of cardiovascular disease even in very young women who take oral contraceptives.

Smoking in combination with oral contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women 35 or older, with smoking accounting for the majority of excess cases.

Mortality rates associated with circulatory disease have been shown to increase substantially in smokers over the age of 35 and non-smokers over the age of 40 among women who use oral contraceptives.

Oral contraceptives may compound the effects of well-known risk factors for coronary artery disease, such as hypertension, diabetes, hyperlipidemias, hypercholesterolemia, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and impair oral glucose tolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see **WARNINGS,** section 9). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors.

b. Thromboembolism

An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to non-users to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. One cohort study has shown the relative risk to be somewhat lower, about 3 for new cases (subjects with no past history of venous thrombosis or varicose veins) and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease due to oral contraceptives is not related to length of use and disappears after pill use is stopped.

A 2- to 6-fold increase in relative risk of post-operative thromboembolic complications has been reported with the use of oral contraceptives. If feasible, oral contraceptives should be discontinued at least 4 weeks prior to and for 2 weeks after elective surgery and during and following prolonged immobilization. Since the immediate postpartum period also is associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than 4 to 6 weeks after delivery in women who elect not to breast feed.

c. Cerebrovascular diseases

An increase in both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes) has been shown in users of oral contraceptives. In general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and non-users for both types of strokes while smoking interacted to increase the risk for hemorrhagic strokes.

In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for non-smokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 7.6 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk also is greater in women 35 or older and among smokers.

d. Dose-related risk of vascular disease from oral contraceptives

A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high density lipoproteins (HDL) has been reported with some progestational agents. A decline in serum high density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the nature and absolute amount of progestogens used in the contraceptives. The amount of both hormones should be considered in the choice of an oral contraceptive.

Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral contraceptive agents should be started on preparations containing the lowest estrogen content that produces satisfactory results for the individual.

e. Persistence of risk of vascular disease

There are three studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40–49 years who had used oral contraceptives for 5 or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. Subarachnoid hemorrhage also has a significantly increased relative risk after termination of use of oral contraceptives. However, these studies were performed with oral contraceptive formulations containing 0.05 mg or higher of estrogen.

2. ESTIMATES OF MORTALITY FROM CONTRACEPTIVE USE

One study gathered data from a variety of sources which have estimated the mortality rates associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is low and below that associated with childbirth. The observation of a possible increase in risk of mortality with age for oral contraceptive users is based on data gathered in the 1970s—but not reported in the U.S. until 1983. However, current clinical practice involves the use of lower estrogen dose formulations combined with careful restriction of oral contraceptive use to women who do not have the various risk factors listed in this labeling.

Because of these changes in practice and, also, because of some limited new data which suggest that the risk of cardiovascular disease with the use of oral contraceptives may now be less than previously observed, the Fertility and Maternal Health Drugs Advisory Committee was asked to review the topic in 1989. The Committee concluded that although cardiovascular disease risks may be increased with oral contraceptive use after age 40 in healthy non-smoking women (even with the newer low-dose formulations), there are greater potential health risks associated with pregnancy in older women and with the alternative surgical and medical procedures which may be necessary if such women do not have access to effective and acceptable means of contraception.

Therefore, the Committee recommended that the benefits of oral contraceptive use by healthy non-smoking women over 40 may outweigh the possible risks. Of course, older women, as all women who take oral contraceptives, should take the lowest possible dose formulation that is effective.

3. CARCINOMA OF THE BREAST AND REPRODUCTIVE ORGANS

Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. The evidence in the literature suggests that use of oral contraceptives is not associated with an increase in the risk of developing breast cancer, regardless of the age and parity of first use or with most of the marketed brands and doses. The Cancer and Steroid Hormone study also showed no latent effect on the risk of breast cancer for at least a decade following long-term use. A few studies have shown a slightly increased relative risk of developing breast cancer, although the methodology of these studies, which included differences in examination of users and non-users and differences in age at start of use, has been questioned. Some studies have reported an increased relative risk of developing breast cancer, particularly at a younger age. This increased relative risk appears to be related to duration of use.

Some studies suggest that oral contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors.

In spite of many studies of the relationship between oral contraceptive use and breast or cervical cancers, a cause and effect relationship has not been established.

4. HEPATIC NEOPLASIA

Benign hepatic adenomas are associated with oral contraceptive use although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases per 100,000 for users, a risk that increases after 4 or more years of use. Rupture of rare, benign, hepatic adenomas may cause death through intra-abdominal hemorrhage.

Studies in the United States and Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral contraceptive users. However, these cancers are extremely rare in the United States and the attributable risk (the excess incidence) of liver cancers in oral contraceptive users is less than 1 per 1,000,000 users.

5. OCULAR LESIONS

There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia; papilledema; or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately.

6. ORAL CONTRACEPTIVE USE BEFORE OR DURING EARLY PREGNANCY

Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. More recent studies do not suggest a teratogenic effect, particularly insofar as cardiac anomalies and limb reduction defects are concerned, when taken inadvertently during early pregnancy.

The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion.

It is recommended that for any patient who has missed 2 consecutive periods, pregnancy should be ruled out before continuing oral contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral contraceptive use should be discontinued if pregnancy is confirmed.

7. GALLBLADDER DISEASE

Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral contraceptive users may be minimal. The recent findings of minimal risk may be related to the use of oral contraceptive formulations containing lower hormonal doses of estrogens and progestogens.

8. CARBOHYDRATE AND LIPID METABOLIC EFFECTS

Oral contraceptives have been shown to impair oral glucose tolerance. Oral contraceptives containing greater than 0.075 mg of estrogen cause glucose intolerance with impaired insulin secretion, while lower doses of estrogen may produce less glucose intolerance. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the non-diabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects, prediabetic and diabetic women should be carefully observed while taking oral contraceptives.

Some women may develop persistent hypertriglyceridemia while on the pill. As discussed earlier (see **WARNINGS**, sections 1a. and 1d.), changes in serum triglycerides and lipoprotein levels have been reported in oral contraceptive users.

9. ELEVATED BLOOD PRESSURE

An increase in blood pressure has been reported in women taking oral contraceptives. The incidence of risk also was reported to increase with continued use and among older women. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing concentrations of progestogens.

Women with a history of hypertension or hypertension-related diseases or renal disease should be encouraged to use another method of contraception. If women elect to use oral contraceptives, they should be monitored closely and if significant elevation of blood pressure occurs oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives and there is no difference in the occurrence of hypertension among ever- and never-users.

10. HEADACHE

The onset or exacerbation of migraine or development of headache with a new pattern which is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause.

11. BLEEDING IRREGULARITIES

Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first 3 months of use. Non-hormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding, as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out.

Some women may encounter post-pill amenorrhea or oligomenorrhea, especially when such a condition was pre-existent.

PRECAUTIONS

1. PHYSICAL EXAMINATION AND FOLLOW-UP

A complete medical history and physical examination should be taken prior to the initiation or reinstitution of oral contraceptives and at least annually during use of oral contraceptives. These physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, including cervical cytology and relevant laboratory tests. In case of undiagnosed, persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be conducted to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care.

2. LIPID DISORDERS

Women who are being treated for hyperlipidemias should be followed closely if they elect to use oral contraceptives. Some progestogens may elevate LDL levels and may render the control of hyperlipidemias more difficult.

3. LIVER FUNCTION

If jaundice develops in any woman receiving oral contraceptives the medication should be discontinued. Steroid hormones may be poorly metabolized in patients with impaired liver function.

4. FLUID RETENTION

Oral contraceptives may cause some degree of fluid retention. They should be prescribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention.

5. EMOTIONAL DISORDERS

Women with a history of depression should be carefully observed and the drug discontinued if depression recurs to a serious degree.

6. CONTACT LENSES

Contact lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist.

7. DRUG INTERACTIONS

Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar association though less marked, has been suggested with barbiturates, phenylbutazone, phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines.

8. INTERACTIONS WITH LABORATORY TESTS

Certain endocrine and liver function tests and blood components may be affected by oral contraceptives:

a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3; increased norepinephrine-induced platelet aggregability.

b. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radioimmunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG. Free T4 concentration is unaltered.

c. Other binding proteins may be elevated in serum.

d. Sex steroid binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged.

e. Triglycerides may be increased.

f. Glucose tolerance may be decreased.

g. Serum folate levels may be depressed by oral contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives.

9. CARCINOGENESIS

See **WARNINGS** section.

10. PREGNANCY

Pregnancy Category X. See **CONTRAINDICATIONS** and **WARNINGS** sections.

11. NURSING MOTHERS

Small amounts of oral contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child.

INFORMATION FOR THE PATIENT

See **PATIENT LABELING.**

ADVERSE REACTIONS

An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see **WARNINGS** section): Thrombophlebitis • Arterial thromboembolism • Pulmonary embolism • Myocardial infarction • Cerebral hemorrhage • Cerebral thrombosis • Hypertension • Gallbladder disease • Hepatic adenomas, carcinomas or benign liver tumors

There is evidence of an association between the following conditions and the use of oral contraceptives, although additional confirmatory studies are needed: Mesenteric thrombosis • Retinal thrombosis

The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug-related: Nausea • Vomiting • Gastrointestinal symptoms (such as abdominal cramps and bloating) • Breakthrough bleeding • Spotting • Change in menstrual flow • Amenorrhea • Temporary infertility after discontinuation of treatment • Edema • Melasma which may persist • Breast changes: tenderness, enlargement, secretion • Change in weight (increase or decrease) • Change in cervical erosion and secretion • Diminution in lactation when given immediately postpartum • Cholestatic jaundice • Migraine • Rash (allergic) • Mental depression • Reduced tolerance to carbohydrates • Vaginal candidiasis • Change in corneal curvature (steepening) • Intolerance to contact lenses

The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted: Pre-menstrual syndrome • Cataracts • Changes in appetite • Cystitis-like syndrome • Headache • Nervousness • Dizziness • Hirsutism • Loss of scalp hair • Erythema multiforme • Erythema nodosum • Hemorrhagic eruption • Vaginitis • Porphyria • Impaired renal function • Hemolytic uremic syndrome • Budd-Chiari syndrome • Acne • Changes in libido • Colitis

OVERDOSAGE

Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea, and withdrawal bleeding may occur in females.

NON-CONTRACEPTIVE HEALTH BENEFITS

The following non-contraceptive health benefits related to the use of oral contraceptives are supported by epidemiological studies which largely utilized oral contraceptive formulations containing estrogen doses exceeding 0.035 mg of ethinyl estradiol or 0.05 mg of mestranol.

Effects on menses: • Increased menstrual cycle regularity • Decreased blood loss and decreased incidence of iron deficiency anemia • Decreased incidence of dysmenorrhea

Effects related to inhibition of ovulation: • Decreased incidence of functional ovarian cysts • Decreased incidence of ectopic pregnancies

Effects from long-term use: • Decreased incidence of fibroadenomas and fibrocystic disease of the breast • Decreased incidence of acute pelvic inflammatory disease • Decreased incidence of endometrial cancer • Decreased incidence of ovarian cancer

CURRENT PROBLEMS IN OBSTETRICS, GYNECOLOGY AND FERTILITY

Editor-in-Chief: Robert L. Barbieri, MD
State University of
New York at Stony Brook

Current Problems in Obstetrics, Gynecology and Fertility brings you the authoritative, practical information you need to stay current in your specialty and to provide the best possible care to patients.

- Each bimonthly issue provides in-depth, monograph-length coverage (40-60 pages) of a clinical topic of vital interest to practitioners today.
- Topics are selected for relevance to your daily practice: preconceptual counseling, infertility, endocrine problems, high-risk obstetrics, diagnosis and treatment of primary and secondary amenorrhea, pediatric and adolescent gynecology, and more.
- Authors are selected for their expertise; you'll benefit from their balanced perspective on the topic and their wealth of clinical experience.
- Each article is extensively referenced, saving you hours of library research.

Stay at the forefront of your specialty! Subscribe today by returning the order form or by calling our toll-free number.

Yes! Please begin my subscription to ***Current Problems in Obstetrics, Gynecology and Fertility*** (6 issues per year).

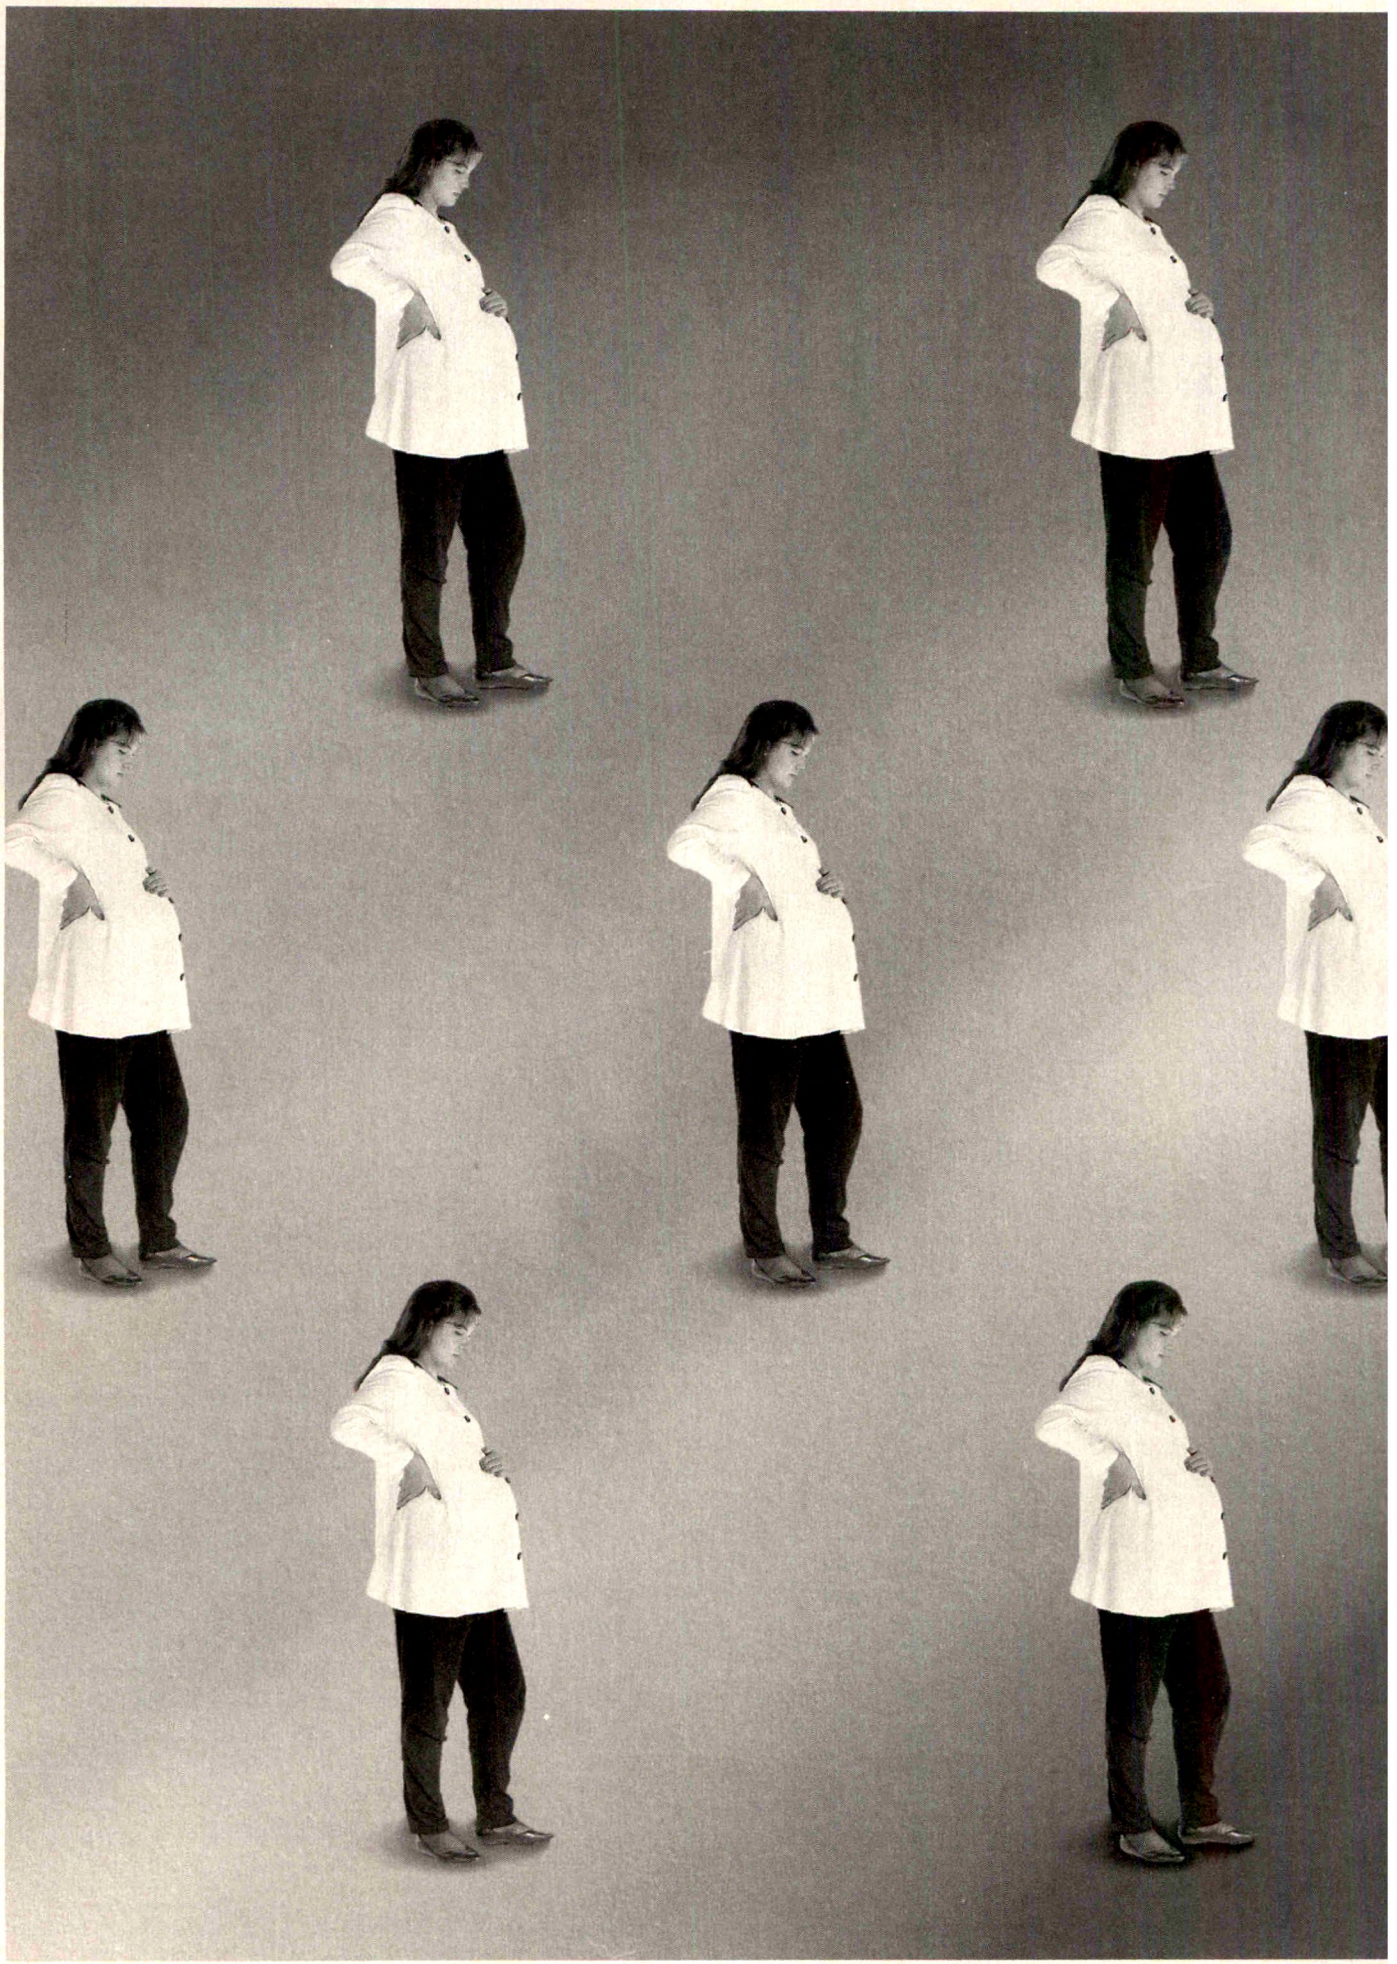
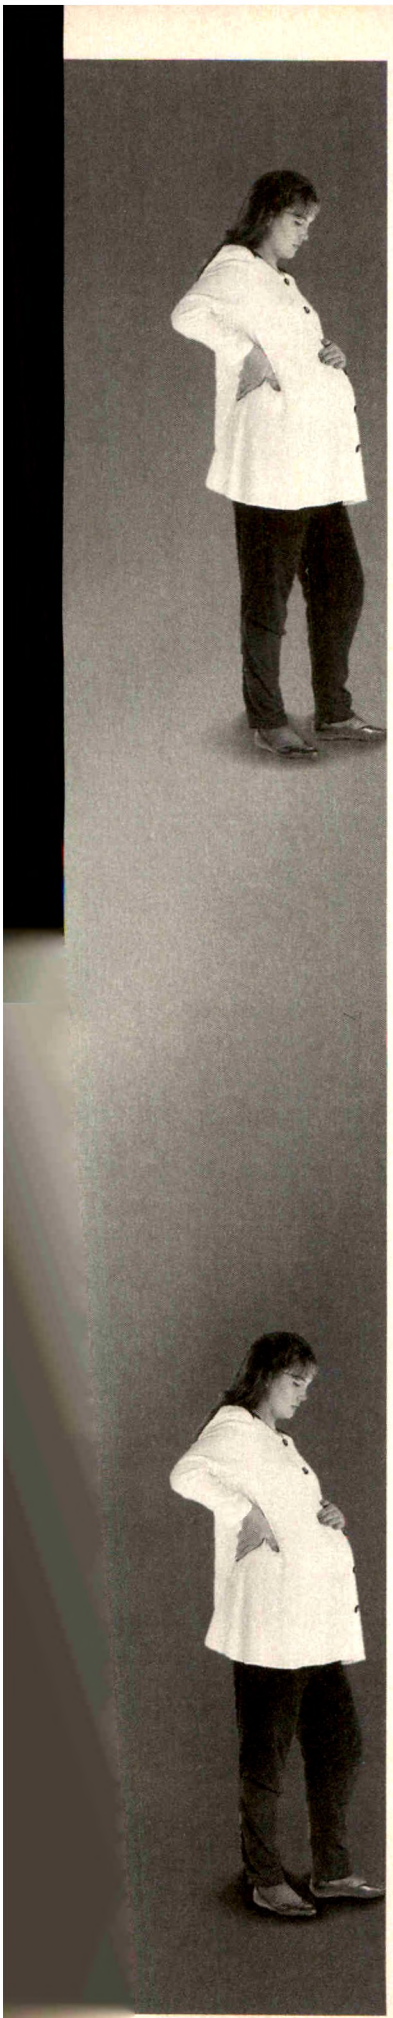
Important subject. Important hands-on methodology.



Exceptional skills are born of exceptional training. And there are none better than skills gained on a live, pregnant patient. For the last decade, we've emphasized not only the *how* of the science of ultrasound, but also the *why* behind each technique.



We offer comprehensive training seminars in abdominal, vascular, obstetric/pelvic, and cardiac ultrasound. And, for your convenience, our seminars are held in major cities across the United States as well as at our modern new facility in the Dallas area. We offer a variety of two-, three-, and five-day programs at reasonable fees. Classes are roughly half theory and half intensive hands-on training. Class size is strictly limited, and postconference support is free to our guests--*forever.*

All of our seminars are SDMS-approved for CEUs. Call KMA 24 hours a day for a free information kit that tells you about us and any of the twenty different seminars we conduct regularly. For exceptional abdominal/obstetric/pelvic imaging, put your hand in our hands. Just call (214) 402-8250.

If Every Delivery Were The Same...

...We'd Only Make One IUP Catheter

EVERY DOCTOR, EVERY HOSPITAL, EVERY SITUATION IS DIFFERENT. WE UNDERSTAND. THAT'S WHY WE MANUFACTURE A COMPLETE LINE OF 5 DIFFERENT IUP CATHETERS. AND WE'RE THE ONLY ONE COMPANY TO DO THAT.

INTRAN, OUR SENSOR-AT-THE-TIP CATHETER WAS THE FIRST TO MEASURE PRESSURE AT THE SOURCE WITH OUR PATENTED MICRO-CHIP TECHNOLOGY. NOW WE'VE ADDED A NEW MODEL, INTRAN-III, FOR 3 COMPLETELY DISTINCT INTRAN CATHETERS. AND OUR 2 "FLUID FILLED" MODELS OFFER YOU THE CHOICE OF A PRE-ASSEMBLED KIT, OR A SINGLE CATHETER TO USE WITH YOUR EXISTING TRANSDUCER. TOGETHER THESE CATHETERS PROVIDE EVEN MORE OF THE PERFORMANCE AND CONVENIENCE YOU'VE COME TO TRUST FROM UTAH MEDICAL PRODUCTS.

A choice of INTRAN sensor-at-the-tip, or "fluid filled" catheters. Only from Utah Medical Products.

GO AHEAD AND GROW...WE'LL BE READY FOR YOU. THE CATHETER YOU'RE USING TODAY MAY NOT BE THE ONE YOU NEED TOMORROW. WHEN YOU'RE READY TO CHANGE, UTAH MEDICAL PRODUCTS IS THE ONLY COMPANY THAT OFFERS YOU THIS FLEXIBILITY IN IUPC PRODUCTS. YOU CAN BE SURE THAT AS YOUR NEEDS GROW, UTAH MEDICAL WILL BE THERE WITH THE TECHNOLOGY TO HELP MAKE IT HAPPEN.

SO, WHILE THE COMPETITION CONTINUES TO TREAT YOU LIKE EVERYONE ELSE, REMEMBER UTAH MEDICAL PRODUCTS. THE LEADER IN IUP CATHETER TECHNOLOGY. WE KNOW YOUR NEEDS ARE UNIQUE.

For more information on our complete line of IUP catheters, contact our Customer Service Department. 1-800-533-4984

Healthline

HEALTHLINE is a monthly, 16-page publication offering up-to-date information on a wide variety of health issues of concern to your patients.

Presented in an attractive, two-color format, HEALTHLINE features a concise, easy-to-read style that's ideal for patient education. HEALTHLINE makes excellent waiting room literature.

- Provides the latest news on disease prevention, nutrition, exercise, mental health, aging, child health, and other topics of interest.
- Alerts your patients to warning signs and symptoms requiring professional attention.
- Presents reliable, *readable* articles written by a national network of doctors, nurses, psychologists, and other health professionals. Edited by Paul M. Insel, PhD, and Walton T. Roth, MD, of the Stanford University School of Medicine.

Mosby–Year Book offers a **special subscription rate** on multiple-copy orders of HEALTHLINE, for waiting room use or for handouts (see chart). Use the attached coupon to place an order or to request a sample issue.

Or call toll-free to order: 1-800-325-4177, ext. 4351. Outside the U.S., call (314) 453-4351.

Anticonvulsant effects of magnesium sulfate on hippocampal seizures: Therapeutic implications in preeclampsia-eclampsia

David B. Cotton, MD, Cynthia A. Janusz, BS, and Robert F. Berman, PhD
Detroit, Michigan

OBJECTIVE: The objective of this study was to determine whether magnesium sulfate has central anticonvulsant effects.
STUDY DESIGN: In three experiments we investigated the anticonvulsant properties of magnesium sulfate on the hippocampus because of its high density of *N*-methyl-D-aspartate receptors and link to clinical epilepsy. Seizure activity was elicited in the hippocampus of rats or in in vitro hippocampal brain slices. The effects of magnesium on seizure activity were determined.
RESULTS: (1) Intraperitoneal magnesium sulfate (270 or 360 mg/kg) failed to block hippocampal seizures but reduced electroencephalographic amplitude and seizure duration. (2) Injection of magnesium sulfate directly into a seizure focus blocked seizures and elevated seizure thresholds. (3) Low magnesium levels produced epileptiform activity in an in vitro hippocampal brain slice preparation; the epileptiform activity was reversed by increasing the magnesium concentration.
CONCLUSIONS: Magnesium sulfate has central anticonvulsant activity on hippocampal seizures, implicating the *N*-methyl-D-aspartate receptor in eclamptic seizures and in the therapeutic efficacy of magnesium sulfate. (AM J OBSTET GYNECOL 1992;166:1127-36.)

Key words: Magnesium sulfate, hippocampus, seizures, eclampsia

Magnesium sulfate has been used for >60 years to prevent and treat eclamptic seizures.[1-3] In spite of magnesium sulfate's empiric success in obstetrics, the literature of other medical disciplines has decried its use on the grounds that it does not have any central inhibitory action and merely masks seizures via peripheral neuromuscular blockade.[4-7] However, on the basis of the well-documented clinical response of eclamptic seizures to magnesium sulfate in the absence of any neuromuscular blockade, Pritchard[8] has proposed that magnesium sulfate does have central effects.

Experimental work in dogs, cats, and subhuman primates also provides support for a central mechanism of action. Borges and Gücer[9] showed that intravenous magnesium sulfate infusion suppressed neuronal burst firing and decreased interictal spike frequency in a penicillin-induced epilepsy model. Suppression occurred at serum magnesium levels well below those required for complete neuromuscular blockade; Borges and Gücer concluded that magnesium sulfate does have a central effect.

In a similar model of penicillin-induced epileptic foci in cats Koontz and Reid[10] were unable to duplicate Borges and Gücer's[9] findings. In Koontz and Reid's model a saline-infused group had the same rapid decrement in seizure activity as the group receiving magnesium sulfate. Koontz and Reid[11] later performed an experiment with the same seizure model to determine the effect of pretreatment with magnesium sulfate; again, they could not document any anticonvulsant effect of magnesium sulfate. They concluded that parenteral magnesium sulfate had no demonstrable anticonvulsant effect in the penicillin-induced seizure focus model in cats.

In another experiment, Hilmy and Somjen[12] demonstrated a fourfold to sevenfold greater deposition of magnesium in peripheral tissues as opposed to brain tissues after intravenous magnesium administration. These investigators concluded that magnesium acts primarily through neuromuscular blockade and that a barrier mechanism protects the central nervous system from high levels of magnesium.

Others have suggested that in eclampsia any apparent central effects of magnesium sulfate must be the result of disruption of the blood-brain barrier and leakage of magnesium into the brain.[4, 10] Donaldson[4] expanded on these observations and concluded that magnesium sulfate does not treat eclamptic convulsions and adds substantial risks to mother and baby.

Because of these disparate conclusions regarding magnesium sulfate's mechanism of action, we examined in rats the effects of magnesium sulfate on seizures initiated in the hippocampus, a brain region with a low seizure threshold and a high density of *N*-methyl-D-

6/6/35626

aspartate receptors. A study of hippocampal seizures should provide a sensitive index of the possible central nervous system effects of magnesium sulfate. The high density of *N*-methyl-D-aspartate receptors is also of interest because these receptors have been linked to various models of epilepsy and are blocked by magnesium.[13]

Material and methods

Surgical preparation. Male Long-Evans rats (Harlan Sprague-Dawley Inc., Indianapolis) were individually housed in stainless steel cages in an environmentally controlled vivarium under 12-hour light-dark cycles. Animals had free access to food throughout the experiments. Twelve animals (275 to 300 gm) were surgically anesthetized (60 mg/kg sodium pentobarbital intraperitoneally) and stereotaxically implanted with chronically indwelling bipolar electrodes (MS-303/2, Plastics One Inc., Roanoke, Va.) aimed for the dorsal hippocampus. The stereotaxic coordinates were 4.0 mm posterior bregma, 2.0 mm lateral from midline, and 4.0 mm ventral to the superior surface of the level skull. The electrode assembly was chronically attached to the skull with three stainless steel jeweler's screws and acrylic cement. Animals were allowed 1 week of postsurgical recovery before further treatments were begun. An additional group of 5 male Long-Evans rats (275 to 300 gm) were surgically implanted with chemitrodes into the dorsal hippocampus as described above. The chemitrode, which permitted electric stimulation and intracranial drug injection at the same brain site, consisted of a bipolar electrode (MS303/3, Plastics One Inc.) cemented to a 23-gauge stainless steel cannula. A 30-gauge obturator plugged the cannula until the time of injection. The ends of the electrode extended 0.5 mm past the end of the cannula. The coordinates for implantation were the same as those described above. A 1-week postsurgical recovery period was again used. A final group of 10 male Long-Evans rats (200 to 260 gm) were used for the in vitro hippocampal brain slice experiments as described below.

Experimental design and protocol

Experiment 1. In this experiment the effects of intraperitoneal injections of magnesium sulfate at 270 and 360 mg/kg on hippocampal epileptiform afterdischarges were determined. Rats implanted with bipolar electrodes in the dorsal hippocampus were placed into a Plexiglas acrylic plastic recording chamber and leads from a polygraph (model 7, Grass Instruments Co., Quincy, Mass.) were attached to the implanted electrodes. Baseline electroencephalographic activity was recorded from the hippocampus via the implanted electrodes. One-second trains (100 Hz, 1-millisecond pulse duration, biphasic, square waves) of low-intensity electric stimulation were delivered through the implanted electrodes beginning at a current intensity of 10 μA. Stimulation intensity was increased in steps of 10 μA until a brief, 5- 10-second epileptiform afterdischarge was recorded from the hippocampus immediately after stimulation. The level of stimulation that evoked an afterdischarge was defined as the afterdischarge threshold; this threshold was used for all drug studies. Electric stimulation was delivered by a stimulator (model S88, Grass Instruments) equipped with two constant-current units (Photoelectric Stimulus Isolation Unit, constant current output, Grass Instruments). An oscilloscope (502A, Tektronix, Inc., Portland, Ore.) was used to monitor the amplitude of the electrical stimulation. Twenty-four hours after afterdischarge threshold determination, the animals were returned to the recording chamber. Three to 5 minutes of baseline electroencephalogram was first recorded, with recording continuing throughout the session. Animals were then injected intraperitoneally with either 270 or 360 mg/kg magnesium sulfate or a volume of saline solution equal to that used for the 360 mg/kg dose on one of three test days. The magnesium sulfate doses were chosen on the basis of an earlier study that reported the anticonvulsant effects of magnesium sulfate in rats.[14] The order of drug administration was randomized across days. Ten minutes after injection animals were stimulated through the implanted electrodes at the afterdischarge threshold current. Epileptiform afterdischarge duration, frequency and electroencephalographic amplitude before and after the seizure were recorded. Finally the duration of postictal electroencephalographic depression was determined. All drug injections were separated by a minimum of 48 hours. Magnesium sulfate was made up in sterile saline solution at a concentration of 90 mg/ml.

Serum magnesium levels were measured immediately before and at timed intervals after intraperitoneal injection of magnesium sulfate in 10 animals. Each rat was surgically anesthetized and implanted with a chronic, indwelling jugular catheter. The catheters were constructed of polyethylene tubing, filled with heparinized saline solution to reduce obstruction of the cannula, and sealed with a metal pin. Catheters were flushed twice daily with heparinized saline solution, and blood samples were taken 3 days after surgery. In brief, rats were injected intraperitoneally with either 180, 270, or 360 mg/kg of magnesium sulfate. At 0, 5, 15, 30, or 60 minutes after injection the pin was removed from the catheter and an 18-gauge needle and syringe inserted into the end of the catheter. Then 0.5 ml samples of blood were collected in 1 ml Microtainer vials (Becton-Dickinson, Rutherford, N.J.). Magnesium levels in 0.7 μl serum samples were analyzed colorimetrically (Eastman Kodak Co., Rochester, N.Y.).

Experiment 2. Direct intracranial injections of magnesium sulfate were made into the dorsal hippocampus through the chronically implanted chemitrodes to determine the effects of magnesium sulfate on seizure activity directly at the seizure focus. In brief, the afterdischarge threshold was determined for these animals as described for experiment 1. Again, an electroencephalographic recording was taken continuously throughout this experiment. Animals were then injected with 1 μl of saline solution or 1 μl of saline solution containing an empirically chosen dose of 50 μg of magnesium sulfate.[15] Five minutes after chemitrode injection animals were stimulated at the afterdischarge threshold, and the afterdischarge duration and spike frequency were determined. Chemitrode injections were made with a 10 μl microsyringe (Hamilton Co., Reno, Nev.) attached to a 30-gauge injection needle cut to fit the implanted chemitrode cannula.

Injections were made over a 60-second period; the injection needle was left in place an additional 60 seconds to ensure drug delivery to the hippocampus as previously described.[15] If drug injection blocked the afterdischarge, current levels were raised in steps of 10 μA until an afterdischarge was elicited.

Experiment 3. Ten rats (200 to 260 gm) were decapitated and their brains quickly removed. The brain was placed on its dorsal surface; the hippocampus was rapidly dissected on ice at 4° C as previously described.[16] The hippocampus was placed onto a tissue slicer (Stoelting Co., Wood Dale, Ill.), and 400 μm slices were cut at a 70 degree angle perpendicular to its septotemporal axis. Slices were immediately placed into cold, oxygenated (95% O_2/5% CO_2) artificial cerebrospinal fluid consisting of 2.4 mmol/L calcium chloride, 1.3 mmol/L magnesium sulfate, 5 mmol/L potassium chloride, 120 mmol/L sodium chloride, 1.24 mmol/L sodium biphosphate, 26 mmol/L sodium bicarbonate, and 10 mmol/L dextrose. The magnesium-free medium was prepared by omitting magnesium sulfate. All slices were transferred to artificial cerebrospinal fluid within 7 minutes from the time of death to ensure viability of the tissue. Slices were gently transferred to the recording chamber. The recording chamber was constructed of transparent Plexiglas acrylic plastic. The atmosphere within the chamber was humidified, oxygenated, and heated to 34° C. A brain slice well on which nylon netting was stretched was placed into the chamber and contained 2 ml of artificial cerebrospinal fluid. Hippocampal slices were placed on the netting. Under these condition stable electrophysiologic activity can be maintained in brain slices for 8 to 12 hours. Slices were allowed to equilibrate to the chamber for 1 hour before electrophysiologic recordings were begun. Extracellular recordings were made with glass micropipettes filled with 2 mol/L sodium chloride and with impedances between 1 to 4 megohms. The tip of the recording electrode was placed into the pyramidal cell layer of the CA3 subregion of the hippocampus at a depth of approximately 70 to 100 μm with a hydraulic micropositioner (model 650, David Kopf Instruments, Wood Dale, Ill.). A concentric bipolar, tungsten microstimulating electrode was used to antidromically stimulate the Schaffer collateral axons in the stratum radiatum of CA3. Extracellular field potentials recorded from pyramidal cells in CA3 were amplified 1000-fold (model DAM-50, World Precision Instruments, New Haven, Conn.), visualized on a digital storage oscilloscope (model 4094C, Nicolet, Madison, Wisc.) and stored on disk for later analysis. Electric stimulation (single 0.1-millisecond monophasic square-wave pulses, 5 to 30 V) was delivered by a stimulator (model S-48, Grass Intruments) and PSIU-6 stimulus isolation unit. Stimulation of the Schaffer collateral fibers was delivered every 60 seconds, and the intensity was adjusted until a stable extracellular field potential was obtained.

After 15 to 20 minutes of superfusion with normal artificial cerebrospinal fluid (i.e., magnesium-containing), magnesium-free artificial cerebrospinal fluid was introduced. Evoked field potentials continued to be recorded every 60 seconds. After 20 to 25 minutes in a magnesium-free artificial cerebrospinal fluid magnesium was added back to the superfusion solution at a concentration of 90 and then 180 μmol/L. The occurrence of epileptiform bursting under magnesium-free conditions was recorded, as were the effects of the readdition of magnesium sulfate.

Histology. At the end of experiments 1 and 2 animals were injected with an overdose of sodium pentobarbital (120 mg/kg intraperitoneally) and perfused transcardially with 0.9% saline solution followed by 10% formalin. The brains were then frozen-sectioned at 20 μm, mounted on microscope slides, and stained with cresyl violet. The precise locations of the implanted electrodes and chemitrodes were then verified microscopically under 40× magnification.

Data analysis. Data were analyzed by a one-way analysis of variance. Post hoc testing was performed when appropriate with the Newman-Keuls test. Values are expressed as mean ± SEM. The significance level was set at $p < 0.05$.

Results

Experiment 1. Intraperitoneal injections of magnesium sulfate produced moderate levels of ataxia, muscular weakness, and lethargy at 270 mg/kg, with severe effects seen at the 360 mg/kg dose. The onset of muscular weakness was within 2 minutes after injection, and animals typically showed complete recovery within 40 to 60 minutes.

The effects of intraperitoneal injections of magne-

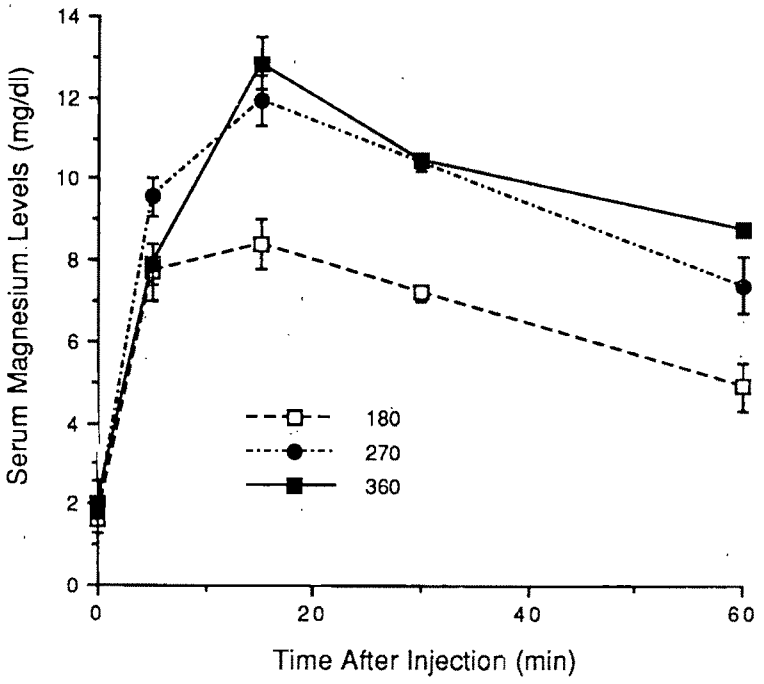

Fig. 1. Serum magnesium levels over a period of 1 hour after intraperitoneal injection of 180, 270, or 360 mg/kg of magnesium sulfate.

Table I. Summary of effects of intraperitoneal injections of magnesium sulfate on hippocampal electroencephalographic seizure threshold, seizure duration, and hippocampal electroencephalographic amplitude

Group	*After discharge threshold (μA)*	*After discharge duration (sec)*	*Electroencephalographic amplitude (% baseline)*
Saline solution (n = 11; mean ± SEM)	72 ± 27	34.6 ± 5.6	100
Magnesium sulfate 270 mg/kg (n = 11; mean ± SEM)	109 ± 40	24.7 ± 5.6	84.6 ± 3.6*
Magnesium sulfate 360 mg/kg (n = 11; mean ± SEM)	90 ± 27	19.0 ± 2.9*	69.1 ± 3.6*

*$p < 0.05$ versus saline-injected control.

sium sulfate on hippocampal afterdischarges are shown in Table I. As shown in the table, magnesium sulfate injections did not affect the afterdischarge threshold for producing hippocampal afterdischarges. All animals showed afterdischarges at or near their individual afterdischarge thresholds regardless of the presence of magnesium sulfate. However, the duration of the afterdischarge was significantly reduced after 360 mg/kg of magnesium sulfate compared with saline-injected controls. In addition, electroencephalographic amplitude was significantly reduced when measured 10 minutes after magnesium sulfate injection but before electric stimulation was administered.

The serum magnesium levels after intraperitoneal injection of either 180, 270, or 360 mg/kg of magnesium sulfate in 10 rats are illustrated in Fig. 1. Values are expressed as mean ± SEM. As shown, mean baseline serum magnesium levels were 1.76 mg/dl (0.72 mmol/L). After magnesium sulfate injection there was a rapid rise in serum magnesium levels, which peaked at approximately 15 minutes, followed by a gradual decrease thereafter. The peak elevation in serum magnesium was 12.8 mg/dl (5.28 mmol/L) for the 360 mg/kg dose measured 15 minutes after injection. These serum magnesium levels are similar to those previously reported in rats receiving the same dose of magnesium sulfate.[14]

Experiment 2. The effects of direct chemitrode injections of magnesium sufate into the hippocampus on hippocampal electrographic activity are demonstrated in Fig. 2, which shows a dramatic reduction in the electroencephalographic amplitude 5 minutes after injection of 50 μg of magnesium sulfate (Fig. 2, *B*) compared with a comparable saline injection (Fig. 2, *A*). These

Fig. 2. Representative electroencephalographic tracings recorded from hippocampus 5 minutes after 1 μl saline injection (**A**) or 50 μg injection of magnesium sulfate (**B**) into a hippocampal seizure focus, demonstrating the marked reduction in amplitude produced by magnesium sulfate.

effects were evident within 90 seconds of injection. Animals were still during most of the period of electroencephalographic quiescence but did not exhibit muscular weakness, ataxia, or any obvious signs of hypermagnesemia. The effects of direct injections of magnesium sulfate into a hippocampal seizure focus on the afterdischarge threshold are shown in Fig. 3. Injections of 50 μg significantly ($p < 0.05$) elevated the threshold for producing a hippocampal afterdischarge. Representative electroencephalography records from one set of injections are shown in Fig. 4. The afterdischarge threshold after a 1 μl saline injection was 26 μA, as shown in Fig. 4, *A*. No afterdischarge was elicited 5 minutes after a 50 μg injection of magnesium sulfate (Fig. 4, *B*) when stimulation was delivered at the 26 μA afterdischarge threshold. A stimulation current of 287 μA was required to produce an afterdischarge (Fig. 4, *C*).

Experiment 3. Epileptiform bursting of region CA3 pyramidal cells after Schaffer collateral stimulation was observed in all hippocampal brain slices beginning 10 to 15 minutes after the beginning of magnesium-free superfusion. A representative epileptiform burst is demonstrated in Fig. 5, *A*. The average burst duration was 64.5 ± 2.8 milliseconds. Suppression of bursting after the addition of magnesium sulfate to a level of

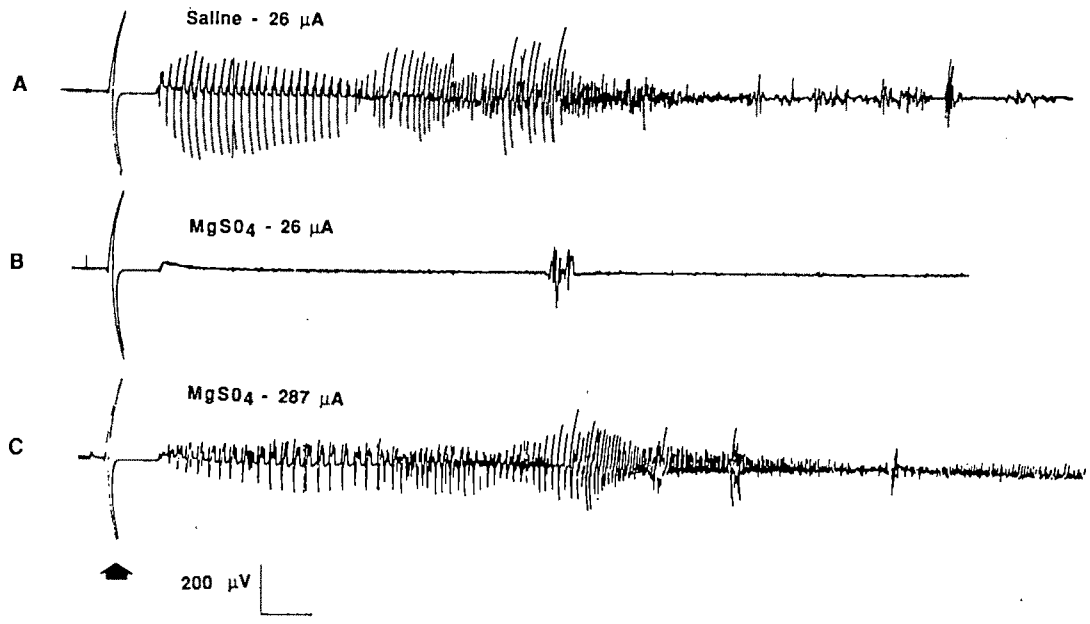

Fig. 4. Representative electroencephalographic records taken immediately after electric stimulation at 26 μA afterdischarge threshold following saline (**A**) or 50 μg magnesium sulfate ($MgSO_4$, **B**) chemitrode injections directly into a hippocampal seizure focus. Note in **B** the absence of afterdischarge at afterdischarge threshold after magnesium sulfate injection. It was necessary to increase stimulation intensity to 287 μA to evoke afterdischarge in this animal as shown in **C**. *Arrow*, Offset of 1-second pulse of electric stimulation.

1.3 mmol/L in the superfusion media is demonstrated in Fig. 5, *B*. In some instances bursting (Fig. 5, *C*) was not totally suppressed by magnesium sulfate (Fig. 5, *D*). Bursting could typically be reinstated by again perfusing the slice in magnesium-free artificial cerebrospinal fluid as shown in Fig. 5, *E*. In all cases the suppression of bursting was relatively rapid, occurring within 10 minutes of addition of magnesium sulfate to the superfusion.

Comment

Our results lead us to conclude that magnesium sulfate does have central inhibitory effects. This conclusion was supported by our experiment in which parenteral injections of magnesium sulfate reduced electroencephalographic amplitude and seizure duration after electric stimulation. Additionally, that a direct intracranial injection of magnesium sulfate could completely block activity of a hippocampal seizure focus also supports this conclusion.

Electroencephalographic studies in preeclamptic-eclamptic patients undergoing magnesium sulfate therapy have not identified any significant electrocortical changes attributable to magnesium sulfate.[17] A possible explanation for our differing results is that hippocampal activity may not be reflected in routine electroencephalographic recordings. Although the hippocampus has a low seizure threshold, changes in electrophysiologic activity produced by magnesium sulfate would be difficult to document without direct subcortical recordings from this structure.

Although we have demonstrated a central anticonvulsant effect of magnesium sulfate in this model, we have not addressed the question of whether magnesium sulfate crosses the blood-brain barrier. In our preparation the placement of electroencephalographic electrodes directly into the hippocampus could cause sufficient disruption of the vasculature to allow magnesium access to the brain interstitium. However, other investigators have carefully evaluated the relationship of serum to cerebrospinal fluid magnesium levels in both human beings and animal models. Thurnau et al.[18] demonstrated that patients with preeclampsia had approximately an 18% increase in cerebrospinal fluid levels after magnesium sulfate therapy. Thurnau et al. concluded that magnesium sulfate does cross the blood-brain barrier in significant amounts during magnesium sulfate therapy.

Oppelt et al.[19] evaluated magnesium levels in the plasma and cerebrospinal fluid of dogs treated with intravenous magnesium sulfate; they concluded that magnesium did cross the blood-brain barrier in small but significant amounts and suggested that an active transport mechanism might be involved. Additionally, Kato and Somjen[20] demonstrated that magnesium significantly depressed neuronal activity in both cortical and spinal cord postsynaptic membranes in cats. These investigators concluded that a rise in magnesium ion

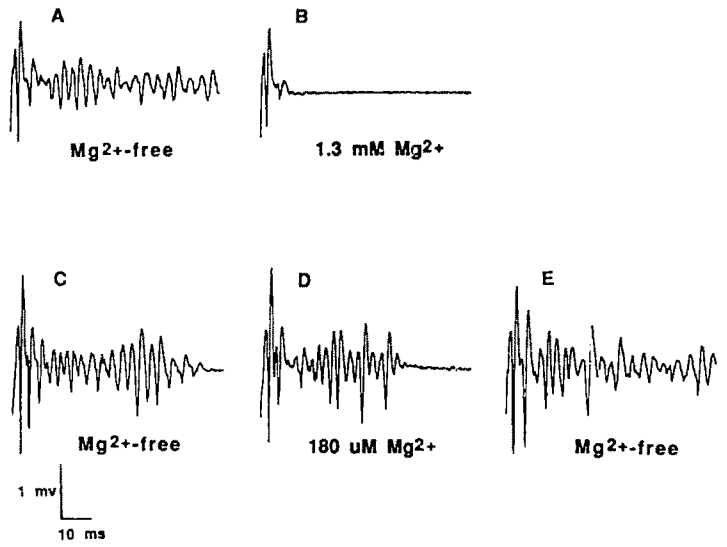

Fig. 5. Representative electrophysiologic field potentials recorded from hippocampal subfield CA3 under magnesium *(Mg)*-free conditions **(A, C)**. Tracings are from two representative hippocampal slices.

concentration in either cerebrospinal fluid or brain by a fraction of the normal levels was sufficient to suppress the activity of central neurons.

In 1974 Chutkow[21] performed a very sophisticated and extensive study of the relationship between cerebrospinal fluid magnesium and the distribution of magnesium in selected regions of the brain during the restoration of magnesium deficits. That study demonstrated that magnesium in cerebrospinal fluid is in equilibrium with an interstitial-cellular pool and suggested that the blood-brain barrier contains an active transport system for magnesium that exhibits regional variation within the brain. Of additional importance is that, although brain magnesium levels did not rise as rapidly as cerebrospinal fluid levels after magnesium replacement, the brain cellular deficits in all areas returned to the normal range within 6 hours of a magnesium injection. In view of those data it appears that even a small increase in the amount of magnesium available to the brain should exert a significant effect.

In spite of our results in this hippocampal model of seizure activity, several other models have failed to demonstrate a central effect of magnesium sulfate. Most of these models, however, have used methods that initiate massive insults to the central nervous system to obtain seizure activity. Choi et al.[22] evaluated the effects of acute changes in plasma magnesium concentration on the threshold for lidocaine-induced seizures in mechanically ventilated rats. Choi et al. hypothesized that magnesium sulfate might be associated with an increased tolerance of the central nervous system to lidocaine toxicity. In that study the lidocaine concentration associated with the onset of electroencephalographic seizures was unaffected by acute hypermagnesemia. This fact led Choi et al. to conclude that the magnesium ion had no anticonvulsant effect. In addition, brain parenchymal magnesium concentrations in that study were similar in the control group receiving saline solution when compared with the magnesium infusion group in spite of a fivefold increase in plasma magnesium levels.

Krauss et al.[23] examined the effects of magnesium sulfate on seizures produced in mice by either maximal electroshock or pentylenetetrazol injection. The electroshock threshold was unaltered by magnesium treatment. Although the magnesium-treated animals had less clonic activity than did the control animals after pentylenetetrazol, the electroencephalographic interictal and ictal seizure discharges were unaffected. The authors attributed the reduction in clonic activity to magnesium blocking the visible manifestations of seizure activity without influencing the neocortical electroencephalographic seizure activity.

In contradistinction to the previously noted studies, Katz et al.[14] recently reported that magnesium sulfate suppressed electroencephalographic seizures induced by hyperbaric oxygen in awake rats. Katz et al. concluded that magnesium sulfate did have a definitive protective action as judged by delaying the electroencephalographic endpoint and that this occurred with an intact blood-brain barrier. Katz et al. suggested that magnesium sulfate might work through calcium-regulated intraneuronal enzymatic processes that alter neuronal excitability and produce seizures. Calcium entry into neurons is regulated by, among other things, specific excitatory amino acid receptor-linked chan-

nels.[24, 25] One type of receptor-channel complex characterized by binding of the excitatory amino acid analog *N*-methyl-D-aspartate has its channel blocked by magnesium ion.[24, 25] Because other blockers of the *N*-methyl-D-aspartate receptor-channel have been shown to be very potent anticonvulsants in seizures induced by maximum electroshock and hyperbaric oxygen, it has been suggested that magnesium sulfate might also act through this mechanism.[13, 14, 26]

We and others have established that low concentrations of magnesium ion can result in epileptiform afterdischarges in hippocampal brain-slice preparations.[27, 28] We chose the hippocampal model of epilepsy because the hippocampus contains one of the highest concentrations of *N*-methyl-D-aspartate receptors of any region in the brain.[29, 30] One of the most likely mechanisms for this seizure activity is activation of the *N*-methyl-D-aspartate receptor. It is possible that in this hippocampal model magnesium sulfate exerted its seizure activity suppression via the *N*-methyl-D-aspartate receptor. On the basis of these data, we speculate that excitatory amino acid receptors such as the *N*-methyl-D-aspartate receptor may play a role in the genesis of eclamptic seizures and may explain, in part, the therapeutic efficacy of magnesium sulfate in this disorder.

We conclude that magnesium sulfate does exert central anticonvulsant effects on hippocampal seizure activity based on data derived from both in vivo and in vitro seizure models.

Discussion

DR. ALLAN B. WEINGOLD, Washington D.C. (Fellow). Although magnesium sulfate remains the drug of choice in this country for the treatment of preeclampsia, its mechanism of action remains unknown. As a result of long but uncontrolled experience, obstetricians are confident of its efficacy and safety. Alternatives to magnesium sulfate are thought to present added risks to mother, fetus, or both.

Yet the treatment of seizures by neurologists, neurosurgeons, and internists does not include the use of magnesium sulfate. The inability to establish a pharmacologic mechanism plays a major role in this dichotomy.

One anticonvulsant action is thought to be a result of peripheral paralysis with blockade of myoneural transmission. Yet the recurrence of seizures during magnesium therapy is rare even when plasma levels are well below those required for neural blockade.

Is there a central action? Several years ago Sibai demonstrated that patients with eclampsia had abnormal electroencephalograms: both paroxysmal spike activity and generalized diffuse slowing. These findings were frequent in spite of serum magnesium levels considered therapeutic (5 to 8 mg/dl).

Drs. Cotton and Berman examined in rats the effects of magnesium sulfate on seizures initiated in the hippocampus, a brain region with a low seizure threshold and a high density of *N*-methyl-D-aspartate receptors. The high density of *N*-methyl-D-aspartate receptors is of interest because these receptors have been linked to various models of epilepsy and are blocked by magnesium.

Stereotaxically implanted bipolar electrodes were placed in the dorsal hippocampus in 24 rats. In 12 animals the effect of low-intensity electric stimulation on the electroencephalogram was studied after intraperitoneal placement of magnesium sulfate 270 or 360 mg/kg—a dose that translates to 19 to 25 gm of magnesium sulfate in the 70 kg pregnant female. Severe effects of ataxia, muscular weakness, and lethargy were observed at the 360 mg/kg dose. In spite of this the injections did not raise the threshold for producing hippocampal discharges, although electroencephalographic amplitude was significantly reduced.

In the second experiment, with the same electrodes in place, direct injections of magnesium sulfate into the dorsal hippocampus were studied. There was a significant reduction in the electroencephalographic amplitude and the animals exhibited no peripheral signs of hypermagnesemia.

In 10 additional animals hippocampal slices were monitored by electrophysiologic recordings as magnesium sulfate was added to the superfusion solution. Suppression of bursting occurred with the addition of magnesium sulfate.

Recent evidence supports the concept that cerebral vasospasm is involved in the pathogenesis of eclampsia. Magnesium has been shown to enhance production of prostacyclin by vascular endothelium and to modify vasoactive substances in serum samples of patients with eclampsia by opposing calcium-dependent smooth-muscle constriction. Magnesium prevents cell death in cultured hippocampal neurons after exposure to ischemia, further suggesting a central mechanism.

Granting the importance of Dr. Cotton's data and these additional observations as to pharmacologic action, we must still address the fact that many centers in the United Kingdom, Scandinavia, New Zealand, and Australia treat preeclampsia-eclampsia with benzodiazepine and antihypertensives and have obtained maternal and perinatal mortality rates that are quite competitive with the gold standard set by Pritchard et al. in Dallas.

Questions for Dr. Cotton:

1. My colleagues in neurology tell me that the hippocampus is involved in focal epilepsy and is usually related to some direct trauma, either metabolic or vascular, to the area. As demonstrated by Sibai and others, seizure activity in eclampsia is generally associated with diffuse abnormalities in the electroencephalogram. Is the hippocampal site an appropriate model for demonstrating the effect of magnesium in the prevention of eclamptic seizures?

2. How can one translate the observation that there was inadequate seizure suppression in the rats given intraperitoneal magnesium sulfate at levels producing systemic toxicity to the use of this drug in the pregnant patient in safe, non-central nervous system–suppressing doses?

3. Dr. Cotton has established credentials as an intensivist in our specialty. Does he believe that the continued use of magnesium sulfate in the patient with eclampsia is justifiable in view of the controversy over its pharmacologic activity and the availability of alternative agents of proven efficacy and apparent equal safety?

I thank Dr. Cotton for submitting his article early and commend him for his study.

Dr. Norman F. Gant, Dallas, Texas. Dr. Cotton, I want to tell you how much I appreciated your presentation, and I will personally provide the sword for Dr. Donaldson to fall on.

With respect to Dr. Weingold's comment about comparable results for the treatment of eclampsia in the United Kingdom, in fact, that is not true. I served 3 years ago, as did Fred Zuspan and Leon Chesley, on a work-study section for the Royal College of Obstetricians and Gynecologists; in fact, maternal mortality, a point most of us can use for a definite end point, has not decreased in 25 years in the United Kingdom with respect to treatment for eclampsia.

Dr. Frederick Naftolin, New Haven, Connecticut. I have the same concerns about the model because in human beings epilepsy is apparently the result of a long-term insult that is usually vascular. Most people believe that it starts sometime at birth and results in abnormalities of somatostatin. I think one possibility in interpreting your results is that the magnesium sulfate may have an effect that goes through somatostatin, an excitatory amino acid that apparently is the cause of or is related to the loss of the cells that we see in patients with hippocampal epilepsy. Have you looked to see whether magnesium sulfate changes somatostatin production or secretion by neurons in the hippocampus?

Dr. Robert Goodlin, Placerville, California. This is an interesting study, Dr. Cotton, but I do not understand why magnesium sulfate works only with eclampsia and not other types of seizures.

Dr. Michael Ross, Los Angeles, California. Very nice work, Dr. Cotton. How repeatable is the threshold

determination in an individual animal? Was it tested several times?

Second, how comparable would the tissue levels of magnesium achieved by the direct intracerebral injection be to a systemic infusion of magnesium?

Finally, have you tested any other anticonvulsants that act by means other than *N*-methyl-D-aspartate receptors to see whether your speculation holds up?

Dr. Robert K. Creasy, Houston, Texas. Just one small methodologic question: Did you confirm at autopsy the placement of your stereotaxically placed needles?

Dr. Cotton (Closing): I thank Dr. Weingold for his thoughtful discussion. The answer to the first question regarding whether the hippocampus is an appropriate model for the study of magnesium sulfate's effect on eclamptic convulsions is, I believe, yes. The model we are studying is also used to initiate epilepsy and full tonic-clonic convulsions. The process by which epilepsy is established is called "kindling," in which the progressive development of seizures occurs with repeated, initially subconvulsive, electric stimulation of discrete areas of the brain. Key brain areas used for kindling include the amygdala, hippocampus, and extrapyramidal structures such as the substantia nigra or caudate nucleus. In the first phase of this study we were only trying to establish whether magnesium sulfate had a central effect. In future studies we plan to look specifically at magnesium sulfate's efficacy in preventing tonic-clonic convulsions. We also believe this model may prove to be useful in studying pregnancy's effect on seizure threshold and could be used to compare the relative efficacy of various anticonvulsants.

This study does not provide a clear answer to the question regarding the observation that intraperitoneal magnesium sulfate did not adequately suppress seizure activity and whether this could be translated to use in human beings. Further studies in our laboratory that address different routes of magnesium sulfate administration and whether longer duration of therapy results in enhanced magnesium transfer to the brain and more efficacious seizure suppression may clarify this question. This initial study only addressed whether magnesium sulfate had a central effect.

Finally, Dr. Weingold, I believe the use of magnesium sulfate is not only justified in the treatment of eclampsia, it is the gold standard against which other anticonvulsants must be measured. I believe this study provides additional information to support its use.

The answer to your question, Dr. Naftolin, is that we have not looked at somatostatin production or secretion in the hippocampus. However, your observation is fascinating, and we will certainly consider pursuing that question.

Dr. Goodlin, legend has it that when obstetricians consult in neurointensive care units, magnesium sulfate has been used with limited success. Perhaps the reason the magnesium sulfate has a less-than-stellar reputation outside of obstetrics is not from lack of efficacy but from lack of use.

Dr. Ross, the threshold determinations were repeated on several occasions; in general, we saw very little variation in the amount of electric stimulation required to establish seizure activity in a given animal. I cannot answer your question regarding the levels of magnesium achieved by intracerebral injection as opposed to systemic administration because we did not measure brain tissue magnesium levels, but I suspect that the levels would be much higher with direct injection. Finally, we have not tested any other anticonvulsants, but we certainly will.

Dr. Creasy, at the end of experiments 1 and 2 the animals were killed and perfused transcardially with 0.9% saline solution followed by 10% formalin. The brains were then frozen-sectioned at 20 μm, mounted on microscopic slides, and stained with cresyl violet. The precise locations of the implanted electrodes were then verified microscopically under 40× magnification.

Bound volumes available to subscribers

Bound volumes of the American Journal of Obstetrics and Gynecology are available to subscribers (only) for the 1992 issues from the Publisher, at a cost of $68.00 for domestic, $95.76 for Canada, and $91.00 for international for Vol. 166 (January-June) and Vol. 167 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the Journal name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, USA; phone (800) 325-4177, ext. 4351, or (314) 453-4351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular Journal subscription.

Comparison of the peritoneal cells elicited by oxidized regenerated cellulose (Interceed) and expanded polytetrafluoroethylene (Gore-Tex Surgical Membrane) in a murine model

A.F. Haney, MD, and Elissa Doty, BA
Durham, North Carolina

OBJECTIVE: The peritoneal fluid cell responses to the available barriers used to prevent postoperative adhesions, oxidized regenerated cellulose (Interceed) and expanded polytetrafluoroethylene (Gore-Tex Surgical Membrane), were compared.
STUDY DESIGN: Oxidized regenerated cellulose and expanded polytetrafluoroethylene were inserted into the peritoneal cavity of mice and the peritoneal fluid cell number, differential cell count, morphologic type, adherence to plastic, and phorbol-12,13-myristate acetate–stimulated hydrogen peroxide production evaluated. Peritoneal fluid cell attachment to oxidized regenerated cellulose and expanded polytetrafluoroethylene was evaluated by electron microscopy.
RESULTS: Oxidized regenerated cellulose promptly elicited increased numbers of large, morphologically activated peritoneal fluid macrophages that adhered more rapidly and produced more hydrogen peroxide than controls. Expanded polytetrafluoroethylene gradually increased the number of normal-appearing peritoneal fluid macrophages with increased hydrogen peroxide production but normal adherence. Macrophages rapidly attached to both materials in vivo, with oxidized regenerated cellulose being rapidly degraded.
CONCLUSION: Oxidized regenerated cellulose, to a greater extent than expanded polytetrafluoroethylene, elicits an acute peritoneal fluid inflammatory exudate in the mouse, which may contribute to the oxidized regenerated cellulose–induced peritoneal injury and de novo adhesions observed in this model. (Am J Obstet Gynecol 1992;166:1137-49.)

Key words: Oxidized regenerated cellulose, expanded polytetrafluoroethylene

The formation of postoperative adhesions, which occur in 50% to 95% of women undergoing gynecologic surgery, continues to plague the reproductive surgeon.[1] Two mechanical barriers have recently been introduced to interpose between surgically traumatized peritoneal surfaces lying in natural apposition; these barriers allow restitution of the mesothelial layer without the formation of adhesions.[2-9] In previous studies evaluating the impact of the materials used in these barriers, it was noted that oxidized regenerated cellulose (Interceed, Johnson & Johnson Medical, Inc., New Brunswick, N.J.) caused a significant injury to the peritoneum, resulting in the formation of de novo adhesions in a murine paradigm. By contrast, expanded polytetrafluoroethylene (Gore-Tex Surgical Membrane, W.L. Gore & Associates, Flagstaff, Ariz.), did not alter the morphologic features of the peritoneum or result in adhesion formation.[10]

These two barriers have distinctly different survival characteristics, with oxidized regenerated cellulose being rapidly degraded enzymatically and removed by tissue phagocytes (i.e., macrophages[11]) while expanded polytetrafluoroethylene remains intact indefinitely.[12] The extent to which biomaterials incite an inflammatory response in tissue has primarily been assessed by implanting the material in a solid organ, such as muscle, and noting the presence of leukocytes in the surrounding area.[13, 14] This is not comparable to the clinical use of these surgical barriers where the material is placed over surgically traumatized peritoneum in contact with the peritoneal fluid with its unique complement of immune cells. When used in an animal model more closely resembling clinical use, oxidized regenerated cellulose, but not expanded polytetrafluoroethylene, unexpectedly caused a localized peritoneal injury and de novo

adhesions,[10] illustrating the problem with the traditional approach to testing of biomaterials.

Although the mechanism of the tissue destruction caused by oxidized regenerated cellulose has not been established, we hypothesize that because of its biodegradability it represents a greater inflammatory stimulus than does expanded polytetrafluoroethylene. To test this hypothesis, we evaluated the effect of intraperitoneal oxidized regenerated cellulose and expanded polytetrafluoroethylene on the cellular constituents of the peritoneal fluid in a mouse paradigm used extensively to study peritoneal wound healing.[15, 16] In addition to determining the numbers of peritoneal fluid leukocytes elicited by each material, we assessed features associated with activation of the peritoneal fluid macrophages, including morphologic features,[17] the rate of adherence to plastic,[18] and stimulated hydrogen peroxide production.[19, 20] The results demonstrate that oxidized regenerated cellulose, to a greater extent than expanded polytetrafluoroethylene, elicits an acute peritoneal fluid inflammatory exudate composed of increased numbers of activated macrophages.

Material and methods

Animals, materials, and media. The animals used in these experiments were 6-week-old, virus-free, female mice weighing 22 to 24 gm. Unless otherwise specified, the animals were CD-1 outbred mice from Charles River Labs (Raleigh, N.C.). Some experiments required larger numbers of peritoneal fluid leukocytes because of losses inherent with Ficoll separation and other logistic considerations. In these situations, syngeneic mice, either CH3/HEJ (Jackson Labs, Bar Harbor, Me.) or C3H/HEN (National Cancer Institute, Bethesda, Md.) animals were used so that cells from several animals could be pooled with minimal risk that minor differences in histocompatibility antigens might activate the cells. The animal care and experiments were approved by the Duke University Institutional Animal Care and Use Committee.

Unless otherwise specified, the medium used in these experiments was Dulbecco's modified Eagle's medium (Hyclone Labs, Ogden, Ut.) buffered with HEPES (Sigma Chemical Co., St. Louis). All reagents were either screened endotoxin free as purchased or were heated to inactivate any residual endotoxin. The serum in the long-term incubations was heat-inactivated fetal bovine serum (Hyclone). Thioglycollate medium (Difco Laboratories, Detroit) was used to elicit peritoneal macrophages. The Ficoll–sodium diatrizoate (specific gravity 1.077, Hystopaque-1077) was obtained from Sigma. Endotoxin-screened, deionized, distilled water (GIBCO, Grand Island, N.Y.) was used for reagent preparation, and to minimize any effect on cell acherence, the phosphate-buffered saline solution used was calcium and magnesium free. The two commercially available surgical barriers, oxidized regenerated cellulose (Interceed) and expanded polytetrafluoroethylene (Gore-Tex Surgical Membrane), were kindly provided by their manufacturers.

Surgical technique. Anesthesia was induced by intraperitoneal injection of 0.2 ml of a 1:1 mixture of ketamine hydrochloride (Ketaset, Aveco Inc., Fort Dodge, Iowa), 5 mg/ml, and xylazine hydrochloride (Rompun, Haver, Mobay Corp., Shawnee, Kan.), 5 mg/ml. The skin was cleansed with 70% ethanol and the surgery was performed under clean but not sterile conditions. The suture used in all cases was 7-0 monofilament Prolene with a BV-1 taper needle (No. 8701, Ethicon, Somerville, N.J.). No animals appeared ill or died in the postoperative interval.

To minimize the effect of surgical trauma on the peritoneum, a midline dorsal skin incision was made in the lumbar area and the skin retracted laterally. A small flank incision was made into the peritoneal cavity and the barrier material inserted and positioned on the lateroventral surface of the peritoneal cavity. Sham-operated control animals simply had the surgical instruments inserted to mimic placement of a surgical barrier.

Peritoneal fluid and barrier collection. The animals were killed by decapitation to minimize traumatic bleeding into the abdominal cavity. Peritoneal fluid was collected by injecting 4 ml of Dulbecco's modified Eagle's medium with added heparin (10 U/ml) into the peritoneal cavity, and the abdomen was gently massaged to disperse the medium. The abdomen was then carefully entered through a ventral abdominal incision at the costal margin, taking care not to spill the peritoneal contents. The medium was aspirated through a pipette with a bulb tip. Another 3 ml of media was instilled, the aspiration process repeated, and the media from each animal were pooled and placed on ice.

Leukocyte differential counts and macrophage identification. Peritoneal fluid differential leukocyte counts were performed on samples prepared with a cytocentrifuge (Shandon Cytospin II, Shandon Southern Products, Ltd., Cheshire, England). The slides were air dried and stained with modified Wright's stain (Sigma Chemical Company). The peritoneal fluid leukocyte counts were determined by counting the cells in a standard clinical hemocytometer. There were five control animals, seven with oxidized regenerated cellulose and seven with expanded polytetrafluoroethylene inserted.

Flow cytometry. Animals had a circular disk (1.6 cm in diameter or approximately 2 cm^2) of either oxidized regenerated cellulose or expanded polytetrafluoroethylene inserted; they were killed 3 days later. The cells were harvested as described and centrifuged gently (50*g* for 20 minutes) at 4° C, the media were aspirated, and the cells were resuspended and washed

twice in phosphate-buffered saline solution. After resuspension in phosphate-buffered saline solution and viability determination by trypan blue exclusion, the suspension was adjusted to a final concentration of 1×10^6 viable cells per milliliter. Aliquots of cells were evaluated by flow cytometry (FACScan, Becton-Dickinson, Rutherford, N.J.). The data were plotted as contour maps for illustrative purposes. The vertical axis represents increasing granularity, whereas the horizontal axis represents increasing cell size of the peritoneal fluid cell population.

Cells from individual CD-1 animals for each of the treatment groups and pooled cells from syngeneic animals with samples from each treatment group were examined in the flow cytometer before and after Ficoll separation. Cells from syngeneic animals were collected and pooled from four control animals, three with oxidized regenerated cellulose and two with expanded polytetrafluoroethylene inserted. The results with the individual CD-1 mice and the syngeneic animals were similar.

Adherence assay. The cells for these studies were obtained in a similar fashion to those for flow cytometry. The cells were centrifuged gently (50*g* for 20 minutes) at 4° C, the media aspirated, the cells resuspended, and the centrifugation repeated. Medium was added to adjust the cell suspension to 3×10^6 viable cells per milliliter, and 0.1 ml of the cell suspension was plated over 0.1 ml of Dulbecco's modified Eagle's medium in the wells of 96-well microtiter plates (Falcon Plastics, Oxnard, Calif.). The plates were then placed in an incubator at 37° C in a humidified atmosphere of 5% carbon dioxide in air from 5 to 60 minutes. At the appropriate times, the wells were washed vigorously with Dulbecco's modified Eagle's medium twice, and 0.2 ml of fresh medium was placed over the remaining adherent cells and the plate returned to the incubator. After the last time point had been reached (60 minutes), a protein assay was performed by the method of Lowry et al. on each well. There were three separate experiments performed with individual mice used for each treatment; the assays were performed in triplicate. Thioglycollate, a known activator of macrophages, was used as a positive control.

To compensate for possible individual animal variation, the experiments were repeated twice with pooled cells from syngeneic animals. The pooled cells were subjected to Ficoll separation to eliminate any contamination with granulocytes. These experiments were performed with 15 control animals, nine with oxidized regenerated cellulose inserted, eight with expanded polytetrafluoroethylene inserted, and three with thioglycollate injected. The assay was again performed in triplicate and the results were similar to those performed with the outbred mice.

Hydrogen peroxide assay. Because of the need to separate granulocytes, which also produce hydrogen peroxide, a Ficoll separation was performed on pooled cells from syngeneic mice. The cells were washed twice with Dulbecco's modified Eagle's medium, resuspended, layered over Ficoll, and centrifuged for 30 minutes at 1200 to 1500 revolutions/min to separate the granulocytes. The interface was harvested and washed twice in Dulbecco's modified Eagle's medium, the viable cells were counted, and the final cell concentration was adjusted to 4×10^6 viable cells per milliliter. Aliquots of 0.1 ml were placed in wells of 96-well microtiter plates. The cells were allowed to adhere for 1 hour in an incubator at 37° C in humidified atmosphere of 5% carbon dioxide in air and washed twice vigorously with phosphate-buffered saline solution to remove nonadherent cells; the hydrogen peroxide assay was performed as previously reported.[21] The amount of hydrogen peroxide produced with and without stimulation by 200 nmol/L phorbol 12,13-myristate acetate was measured as a reflection of optical density in the horseradish peroxidase–phenol red assay. This dose of 12,13-myristate acetate was previously observed to maximally stimulate hydrogen peroxide production in human monocytes. Again, thioglycollate was used as a positive control. The experimental groups were run in triplicate. Three separate experiments were performed with a total of 22 control mice, 13 with oxidized regenerated cellulose inserted, 12 with expanded polytetrafluoroethylene inserted, and five in which thioglycollate was injected in the peritoneal cavity.

Scanning electron microscopy. The retrieved membrane specimens were briskly rinsed in 0.1 mol/L cacodylate and 5% sucrose buffer at pH 7.4 and fixed in 3% gluteraldehyde in this buffer at 4° C overnight. The specimens were then rinsed two times in the buffer for 5 minutes and dehydrated in a standard sequence, critical point dried, and sputter coated with gold-palladium. These preparations were examined and photographed in a scanning electron microscope (JEOL JSM 35C, JEOL, Tokyo). Three separate animals had each membrane inserted, and the scanning electron microscopic appearance was consistent within the two groups.

Statistical analysis. The descriptive statistics used in the figures are means and either standard deviations or standard errors of the mean as indicated. Analysis of variance was used to detect the presence of significant differences and treatment contrasts (least significant difference) used to detect differences at individual data points. For all the statistical analyses, the level of significance was considered to be $p < 0.05$.

Results

Peritoneal cell population. All the cells present in the peritoneal fluid were morphologically identifiable as leukocytes, and the differential counts are depicted in Fig. 1. The relative proportions of the various types

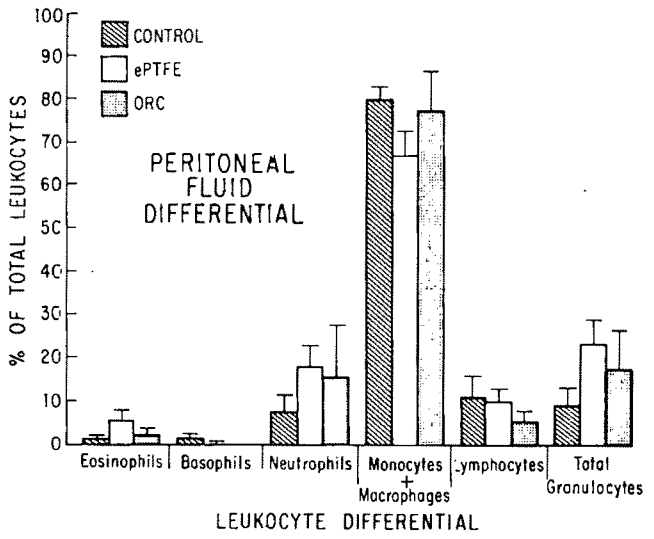

Fig. 1. Peritoneal fluid cell differential counts. Cytospin differential counts are presented. Note that they appear to be comparable regardless of material inserted except for suggestion of difference with slight increase in percentage of granulocytes when expanded polytetrafluoroethylene *(ePTFE)* was inserted. *ORC*, Oxidized regenerated cellulose.

of leukocytes were comparable to those of the control animals, except that there was a slightly greater number of granulocytes, primarily neutrophils, in the animals with expanded polytetrafluoroethylene inserted.

The mononuclear cells in the control and expanded polytetrafluoroethylene mice had the typical appearance of resident peritoneal fluid macrophages (Fig. 2, *A* and *B*). They are larger than lymphocytes with an irregularly shaped nucleus and a relatively small amount of cytoplasmic vacuolization. By contrast, when oxidized regenerated cellulose was inserted the macrophages were larger with very prominent vacuolization and marked ruffling of their plasma membranes, characteristic of activated phagocytes[17] (Fig. 2, *C*). Cytoplasmic debris consistent with ingested oxidized regenerated cellulose was frequently observed.

The total number of peritoneal fluid leukocytes in all the groups is depicted in Fig. 3 as a function of time from insertion of the material. In the control animals there was a gradual increase in the number of resident peritoneal leukocytes over the 4-week period of observation. The presence of oxidized regenerated cellulose was associated with a rapid and marked increase in the number of leukocytes, reaching maximal levels within the first 24 hours after the insertion of the material. This was followed by a gradual return to control levels over the next several days, being indistinguishable from the control animals by 5 days. The animals with expanded polytetrafluoroethylene also experienced an increase in cell number, but more slowly than with the oxidized regenerated cellulose, with a small increase in number of leukocytes on day 3 but a value comparable to controls thereafter.

Flow cytometry. The cytomorphometric patterns of the peritoneal fluid cell populations in the various groups are presented in the contour maps shown in (Fig. 4). In the control animals, the three distinct cell populations, lymphocytes, monocytes-macrophages, and granulocytes were observed. Ficoll separations were used to confirm the identity of granulocytes on the contour maps, as only mononuclear cells (monocytes-macrophages and lymphocytes) remain at the interface. Differential counts of the samples before and after Ficoll separation confirmed the reduction in granulocytes on the contour maps from 8% ± 2% to 2% ± 1%. The monocytes and macrophages were intermediate in granularity but are larger than lymphocytes. The newly recruited monocytes were not distinguishable from resident macrophages, although the former are typically smaller with activation causing macrophages to enlarge.

The insertion of expanded polytetrafluoroethylene resulted in an increase in the number of granulocytes present. The granulocytes were the most identifiably changed in this group, confirming the differential counts. The insertion of oxidized regenerated cellulose resulted in a dramatic shift toward larger macrophages with more granularity, consistent with their cytospin appearance. Oxidized regenerated cellulose produced no change in the granulocyte population from the controls. There was no apparent change in the lymphocyte populations in any of the experimental groups.

Hydrogen peroxide assay. The results of the hydrogen peroxide assays are shown in Fig. 5. Basal hydrogen peroxide production by peritoneal fluid macrophages was not detectable in any group except the

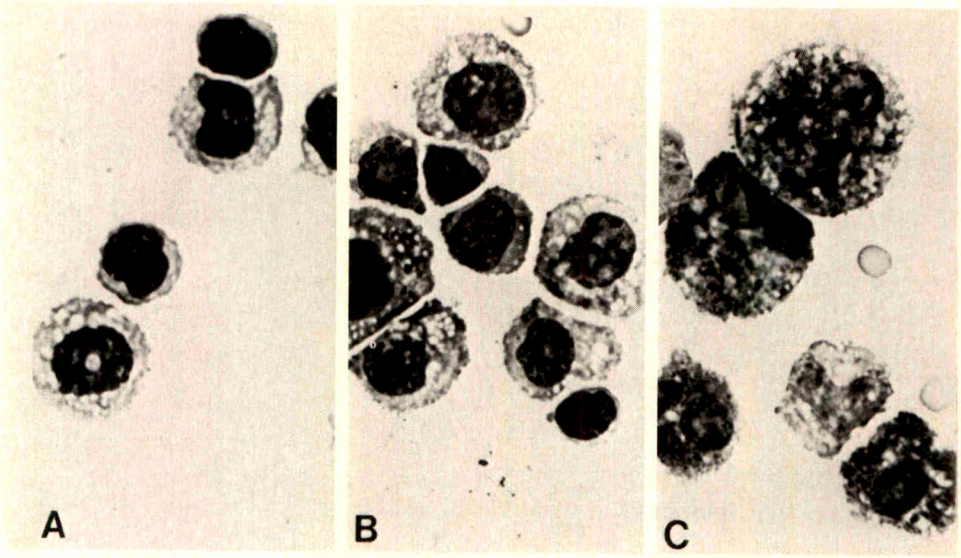

Fig. 2. Photomicrographs of peritoneal fluid macrophages. Peritoneal fluid macrophages from representative control mouse shown in **(A)** and those from animal with expanded polytetrafluoroethylene inserted **(B)** appear comparable. By contrast, macrophages from animal with oxidized regenerated cellulose inserted **(C)** were larger and had irregular plasma membranes and more granular cytoplasm. These photomicrographs were taken from cytospin preparations stained with Wright's stain. (Original magnification ×1000.)

positive thioglycolate control. 12,13-Myristate acetate–stimulated hydrogen peroxide production was noted in all the groups with the control animals' cells being significantly lower than the oxidized regenerated cellulose, expanded polytetrafluoroethylene, and thioglycollate groups. All the stimuli used increased peritoneal fluid leukocyte number and also increased the 12,13-myristate acetate–stimulated hydrogen peroxide production, with only the thioglycollate being sufficiently stimulatory to increase the basal hydrogen peroxide production.

Adherence assay. The rate of adherence for the various groups is presented in Fig. 6. The adherence was measured as cell protein remaining in the wells after vigorous washing and was plotted as a function of time. The rate of adherence was most rapid with the thioglycollate and oxidized regenerated cellulose groups and lower with the macrophages from the control and expanded polytetrafluoroethylene animals. As the cell protein might be influenced by the larger size of the macrophages in the one oxidized regenerated cellulose group, the data were also plotted as the percentage of the maximal adherence at 60 minutes. The data were essentially unchanged, indicating that the peritoneal fluid cells from oxidized regenerated cellulose animals clearly have an increased rate of adherence that is comparable with that of the positive control, thioglycollate.

Appearance of the surgical barriers

Gross findings. The expanded polytetrafluoroethylene remained intact, unchanged, and free-floating in all animals throughout the observation interval. By contrast, the oxidized regenerated cellulose was intact and relatively unchanged 6 hours after insertion but by 24 hours had become relatively gelatinous. By 3 days, the oxidized regenerated cellulose had been degraded to the point that, in most animals, it could not be found except for occasional fragments scattered throughout the peritoneal cavity. No mice in the expanded polytetrafluoroethylene group had adhesions, whereas mice in the oxidized regenerated cellulose group had adhesions with approximately the same frequency as that noted previously (58%).[10]

Scanning electron microscopy. The expanded polytetrafluoroethylene had two cell populations when present at 6 hours, rounded cells with microplicae characteristic of macrophages (confirmed by phagocytosis of polystyrene latex beads and transmission electron microscopy) and flat polygonal cells representing mesothelial cells (Fig. 7). Both cell populations were increased at 24 hours, but the cell density remained relatively light with little cell-cell contact. By 7 days the mesothelial cells virtually covered the expanded polytetrafluoroethylene with only occasional macrophages on the surface. The expanded polytetrafluoroethylene remained free-floating in the peritoneal cavity with the attached cells making no other significant cell contacts.

The oxidized regenerated cellulose had predominantly macrophages adherent at 6 hours, with the numbers of cells increasing rapidly by 24 hours when mesothelial cells first appeared in significant numbers (Fig. 7). In contrast to the expanded polytetrafluoroethylene, the oxidized regenerated cellulose was virtually

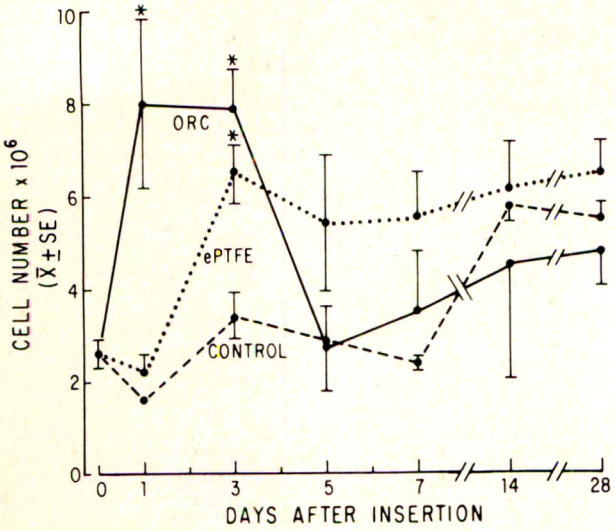

Fig. 3. Peritoneal fluid leukocyte number. Number of peritoneal fluid leukocytes for all three groups is depicted up to 28 days. Number of mice in each group varied as peritoneal fluid cells were used simultaneously in other experiments. Average number of animals for each data point was six. Peritoneal fluid cell numbers for oxidized regenerated cellulose are significantly different from those of controls on days 1 and 3 *(asterisks)*, whereas numbers for expanded polytetrafluoroethylene are different only on day 3. There is a gradual increase in peritoneal fluid leukocyte counts of control animals over interval of observation.

encased by macrophages and mesothelial cells at 24 hours, consistent with an attempt to isolate the degrading oxidized regenerated cellulose. The surface appearance of the cells on the oxidized regenerated cellulose is dramatically different from that of those on the expanded polytetrafluoroethylene, with the cells having very ruffled plasma membranes and extensive intercellular attachments, features suggesting activation. The fragments of oxidized regenerated cellulose remaining at 3 days had an appearance comparable to that of the 24-hour samples.

Comment

Oxidized regenerated cellulose has been viewed as relatively nonreactive, on the basis of traditional biomaterials testing methods, yet it clearly has a destructive effect on normal murine peritoneum.[10] Several factors may contribute to the inability of the solid tissue model to predict the impact of oxidized regenerated cellulose on the peritoneum. First, using histologic examination to determine the extent of the inflammatory exudate surrounding an implant in solid tissue is not an accurate method to assess the number, character, and state of activation of adjacent leukocytes. Second, features other than the chemical composition of the material,

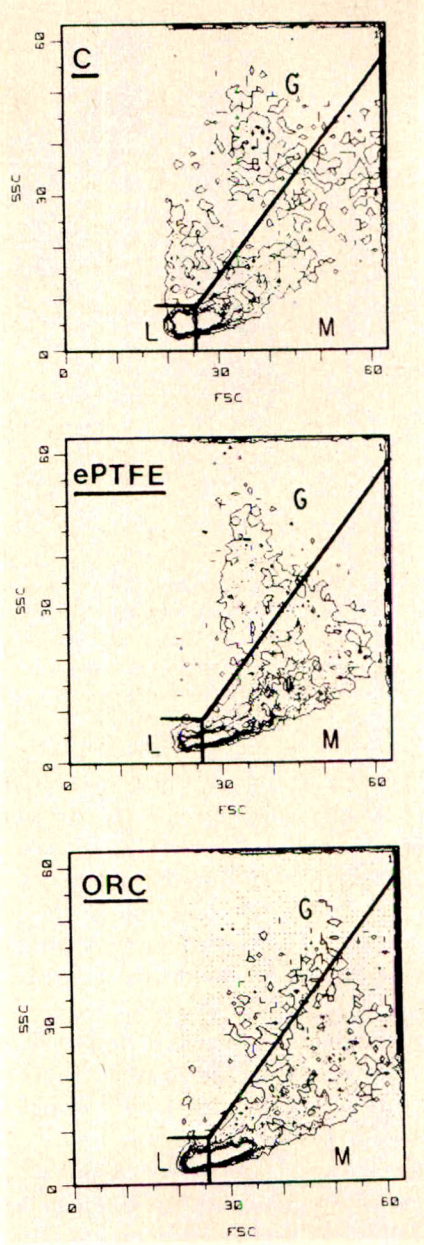

Fig. 4. Flow cytometry contour maps of peritoneal fluid cells. Representative experiment with pooled cells from syngeneic animals is presented. *Vertical axis* represents increasing granularity, whereas *horizontal axis* represents increasing cell size of peritoneal fluid cell population. Areas for individual cell types on basis of differential counts before and after Ficoll separations are marked with *L* for lymphocytes, *G* for granulocytes, and an *M* for monocytes-macrophages. Note all groups had comparable populations of lymphocytes and control animals had scattered distribution of granulocytes and macrophages. The most striking aspect of peritoneal fluid cells of expanded polytetrafluoroethylene *(ePTFE)* animals was an increase in granulocytes, whereas oxidized regenerated cellulose *(ORC)* animals had few granulocytes and much greater diversity in size and granularity in monocyte-macrophage population.

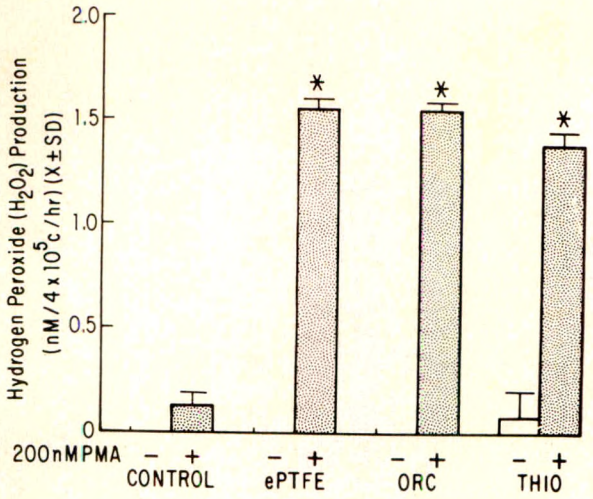

Fig. 5. Hydrogen peroxide secretion by peritoneal macrophages. Basal and 12,13-myristate acetate *(PMA)*–stimulated production of hydrogen peroxide by various groups in a representative experiment is depicted. 12,13-Myristate acetate–stimulated hydrogen peroxide production was significantly increased for all experimental groups *(asterisks)*, whereas only the thioglycollate *(THIO)* group (positive control) had detectable basal hydrogen peroxide production. *ePTFE*, Expanded polytetrafluoroethylene; *ORC*, oxidized regenerated cellulose.

such as its shape or rigidity, may alter the leukocytic response in solid tissue.[22] Last, and most important, implanting the material in a homogeneous solid organ may not reflect the clinical use of the material, as the response may be site specific. This is particularly true when tissue such as peritoneum adjacent to the barrier is not designed to withstand even minor insults and is in contact with peritoneal fluid and its unique complement of immunologically active cells. Thus, as appears to be the case with oxidized regenerated cellulose, a material thought to be nonreactive by traditional biomaterials testing may have unanticipated effects at the site of its clinical use.[10]

The ideal surgical barrier for adhesion prevention would be composed of material that is rapidly biodegradable yet nonreactive. These characteristics are not likely to be simultaneously achievable, as virtually any material that undergoes rapid degradation does so by eliciting a localized inflammatory response. Monocytes are attracted to the site of a foreign material as a result of chemotactic signals integral to the inflammatory process and, most germaine to this situation, dead and dying cells.[17] Once recruited, monocytes undergo differentiation into tissue macrophages[23] and can be activated by a variety of effectors, most prominently by the membrane perturbation accompanying phagocytosis.[17] Activated macrophages can be distinguished morphologically from resident macrophages by their increased size, granularity, and the ruffled appearance of the plasma membrane.[17] There are numerous functional changes resulting from activation, including increased biosynthetic and metabolic activity, more rapid attachment to surfaces,[18] and an enhanced capacity to generate reactive oxygen metabolites.[19, 20] Although these changes may enhance the primary function of macrophages, antimicrobial activity, the simultaneous secretion of proteinases degrades the surrounding extracellular matrix and extends the tissue injury.[17] Furthermore, a secretory product of activated macrophages, interleukin-1, stimulates fibroblast proliferation and collagen synthesis,[24] increasing the potential for adhesions to form during the healing process. Thus, if a barrier elicits an inflammatory exudate, it may further damage the surgically traumatized surface it is trying to isolate and inadvertently increase the likelihood of forming the adhesions it is trying to prevent.

The peritoneal fluid leukocytes elicited by oxidized regenerated cellulose appear distinctly different from those in the control and expanded polytetrafluoroethylene animals. Their morphologic features, coupled with the faster adherence to plastic and marked 12,13-myristate acetate–stimulated hydrogen peroxide production, suggests they are activated. The oxidized regenerated cellulose–induced peritoneal fluid leukocytosis dissipated in several days, coincident with the disappearance of the material and the healing of the peritoneum. This pattern is most consistent with an acute injurious effect of the material and the simultaneous elicitation of an acute inflammatory exudate that dissipates as the material is degraded and the peritoneum recovers from the insult. The direct effect of the oxidized regenerated cellulose on the peritoneum independent of the influence of the elicited leukocytes cannot be addressed in this paradigm. The peritoneal fluid phlogistic response associated with oxidized regenerated cellulose may be a normal component of wound healing after an oxidized regenerated cellulose–induced injury or part of an intense localized inflammatory response elicited to degrade the oxidized regenerated cellulose, consistent with the electron microscopic appearance. Biomaterials have inherent differences in the degree to which they represent inflammatory stimuli, and oxidized regenerated cellulose may have a unique propensity to elicit leukocytes.

Nondegradable materials have been selected for use in surgical devices when they appear to represent a minimal inflammatory stimulus, on the basis of the solid tissue model. These materials may nonetheless elicit a peritoneal fluid leukocytic response.[25] Because expanded polytetrafluoroethylene is not associated with

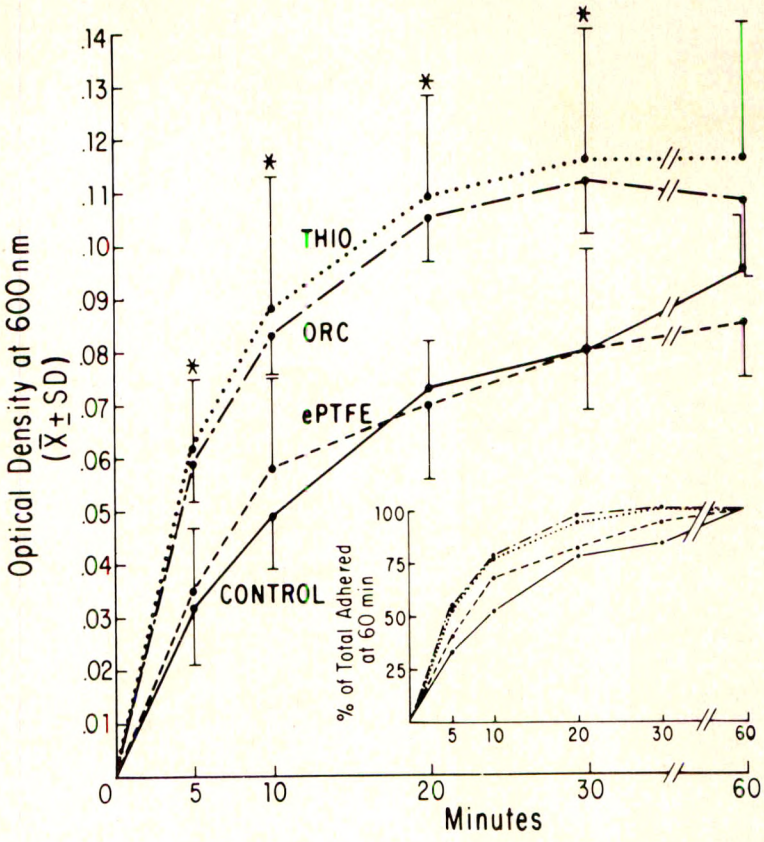

Fig. 6. Peritoneal macrophage adherence assay. Representative experiment with pooled cells from syngeneic animals after Ficoll separation is presented. Rate of adherence of peritoneal fluid cells, as indicated by cell protein in wells, is plotted versus time. Cells were maximally adherent by 60 minutes with total protein somewhat higher in oxidized regenerated cellulose and thioglycollate (positive control) groups. Note that time points on curve for oxidized regenerated cellulose that were significantly different from controls were 5, 10, 20, and 30 minutes *(asterisks)*. No time points on the curve for expanded polytetrafluoroethylene were different from controls. In *inset*, data are replotted as percentage of total protein remaining at 60 minutes, to compensate for possible differences in protein content between groups as a result of increased size after stimulation. Increased rate of adherence of oxidized regenerated cellulose–elicited cells remains.

tissue injury in spite of a mild increase in the number of normal-appearing peritoneal fluid leukocytes, other factors such as the level of activation of the elicited macrophages may be critical.

The pattern of peritoneal fluid leukocytes when expanded polytetrafluoroethylene is inserted is remarkably different from that with oxidized regenerated cellulose, with the morphologic features of the macrophages comparable to those of controls and a more gradual and smaller increase in the peritoneal fluid leukocyte count. Although the expanded polytetrafluoroethylene–induced peritoneal fluid cells could be stimulated to produce hydrogen peroxide comparable to that of the oxidized regenerated cellulose–treated animals, the adherence of the expanded polytetrafluoroethylene–induced cells was not increased over that of controls. These findings suggest that expanded polytetrafluoroethylene generates a minimal peritoneal fluid reaction in spite of the scanning electron microscopy demonstration of intimate cell-material contact. This is consistent with the extensive clinical experience with expanded polytetrafluoroethylene used as a permanent replacement for pericardium to prevent cardiac adhesions.[12]

Species differences are always a concern when data are extrapolated from animal models to humans. The murine model has long been used by immunologists and has contributed substantially to our understanding of the human immune system. In particular, the murine model has proved useful for study of the activation of peritoneal fluid mononuclear phagocytes. In spite of size differences between species, it is unlikely that the

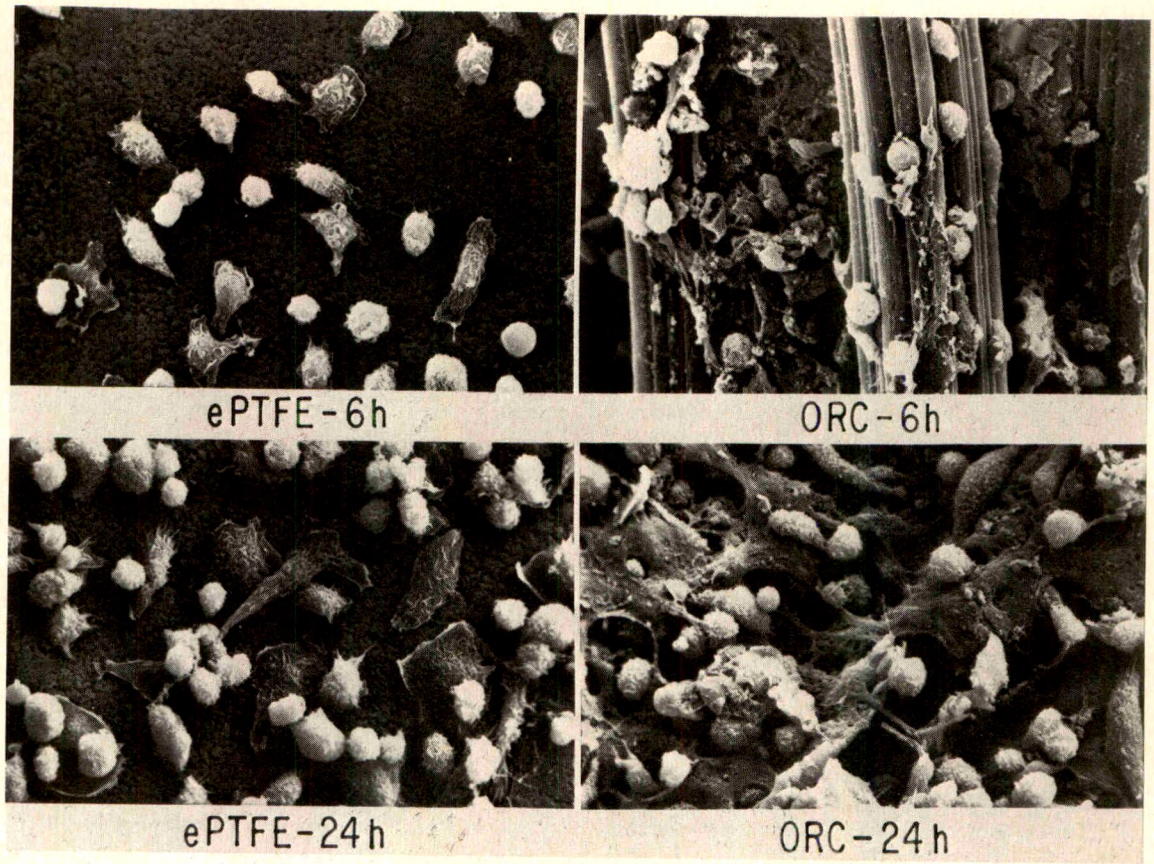

Fig. 7. Scanning electron microscopy of expanded polytetrafluoroethylene *(ePTFE)* and oxidized regenerated cellulose *(ORC)* barriers. Scanning electron micrographs of expanded polytetrafluoroethylene and oxidized regenerated cellulose barriers are presented at 6 and 24 hours after insertion. (Original magnification ×1000.) Note characteristic rounded shape of macrophages and flat polygonal mesothelial cells best demonstrated on expanded polytetrafluoroethylene. Although oxidized regenerated cellulose was visible at 6 hours, it was virtually encased by metabolically active–appearing cell investment by 24 hours (see description in Results).

basic peritoneal immunologic response or the local peritoneal impact of a biomaterial would be substantially different between the mouse and the human.

In summary, the acute peritoneal fluid exudate associated with the insertion of oxidized regenerated cellulose, as well as the tissue destruction and adhesion formation previously observed,[10] suggests that, as currently constructed, oxidized regenerated cellulose may not be an ideal material for use as a surgical barrier to prevent peritoneal adhesions. The fact that expanded polytetrafluoroethylene was not associated with a peritoneal fluid inflammatory response comparable to that with oxidized regenerated cellulose indicates that it represents less of a peritoneal fluid inflammatory stimulus. When the clinical application of a biomaterial is on the peritoneal surface, it may be important to consider the peritoneal fluid leukocyte response, as this may be a more sensitive marker of tissue reactivity than the leukocytic reaction surrounding a biomaterial inserted into solid tissue.

We thank David Chandler and Dorothy Primrose in the Electron Microscopy Laboratory of the Duke University Eye Center and Sara Sparks in the Clinical Flow Cytometry Laboratory of Duke University Medical Center for their expert technical assistance.

Discussion

Dr. Miles Novy, Bearverton, Oregon (Fellow). The etiology of pelvic adhesions includes infection and other types of peritoneal irritation, but surgical trauma is the most important contributing factor.[1] The formation of postoperative adhesions is a major factor in limiting the success rate of reconstructive pelvic surgery for infertility. The mechanism of adhesion formation is a variation of the normal healing process. Injury to the peritoneum increases the permeability of blood vessels, which results in a proteinaceous exudate and coagulum within hours after the injury. Within 12 to 24 hours after injury, the fibrinous coagulum is infiltrated by numerous leukocytes and macrophages. Spontaneous dissolution of the coagulum occurs within a few days by the development of tissue fibrinolytic activity. Mesothelial regeneration of the peritoneal defect is completed by day 8 through metaplasia of underlying fibroblasts or primitive mesenchymal cells. Abnormal peritoneal healing occurs when fibrinolytic activity is inhibited (as by ischemia) and there is persistence of intraperitoneal fibrin. Ingrowth of fibroblasts and vascularization results in permanent adhesion formation.

A variety of methods have been used to prevent the development of adhesions after pelvic surgery, but meticulous surgical technique remains the cornerstone of adhesion prevention. The history of infertility surgery is punctuated by cycles of premature enthusiasm followed by disillusionment with one adjuvant agent after another. We witnessed the widespread use of dexamethasone and promethazine in the 1960s and 1970s. This was followed by enthusiasm for intraabdominal instillation of 32% dextran 70 to provide a flotation bath for abdominal viscera and traumatized peritoneal surfaces. More recently, we have seen the introduction to clinical use of mechanical barriers, notably Interceed, an oxidized regenerated cellulose, and Goretex, a polytetrafluoroethylene fabric, to separate adjoining surfaces during the healing process. As has been true with most other adjuvants for adhesion prevention, Interceed was introduced with a hypothetic rationale for its mechanism of action and limited background work in animal models. A single, prospective, randomized, multicenter clinical trial showed a reduction in peritoneal sidewall adhesion reformation,[2] but the abstruse scoring system used and the limitation to a single surgical site leave room for doubt about its real clinical efficacy. Goretex has found clinical use as a pericardial substitute. Clinical studies are under way but it has not yet been commercially exploited for infertility surgery. Interceed is closely related to oxidized regenerated cellulose (Surgicel, Johnson & Johnson Medical, Inc., New Brunswick, N.J.), differing only in degree of oxidation and the density of the weave pattern. Surgicel, a hemostatic agent, was not efficacious in most animal

models tested and was noted to be adhesiogenic in some.[3, 4] Many of us have been skeptical, to paraphrase an old metaphor, that you could weave a silk purse from a sow's ear. Interceed is being advertised as a nonreactive substance and is openly promoted for use in wrapping the ovaries and fallopian tubes after reconstructive surgery and for covering myomectomy incisions, indications for which there are no clinical or animal studies to document efficacy. Uncontrolled observations in my practice at second-look laparoscopy or repeat laparotomy and discussions with colleagues suggest that Interceed is potentially adhesiogenic at these different sites of application and under varying surgical and pathologic circumstances.

Dr. Haney's research article is a refreshing entry in the midst of this controversy and provides controlled observations on the consequences of applying barrier materials for peritoneal adhesion prevention in a murine animal model. In a companion article to be published in *Fertility and Sterility*,[5] Dr. Haney demonstrated that simple peritoneal apposition of oxidized regenerated cellulose (Interceed) caused localized sloughing of the mesothelial layer and de novo adhesion formation to adjacent viscera in 58% of animals. Neither sham-operated animals nor animals receiving polytetrafluoroethylene (Goretex) had development of peritoneal injury or adhesions.

The objectives of the study reported here were to explore the mechanisms of the peritoneal tissue damage and adhesion formation to the oxidized regenerated cellulose barrier and to characterize and compare the peritoneal inflammatory response with absorbable barrier (oxidized regenerated cellulose) and a nonabsorbable barrier (expanded polytetrafluoroethylene) in the mouse. Oxidized regenerated cellulose is rapidly degraded enzymatically and removed by macrophages, whereas expanded polytetrafluoroethylene remains intact indefinitely. The authors propose that peritoneal damage by oxidized regenerated cellulose is caused by the greater inflammatory response that is elicited in comparison with expanded polytetrafluoroethylene. Previous studies of the inflammatory response to barrier materials have been confined largely to soft tissues or to histologic studies at the site of injury. In the current work more specific qualitative and quantitative assays of peritoneal leukocyte function were used, i.e., differential counts and macrophage identification by flow cytometry, adherence assays, and hydrogen peroxide assays to determine macrophage activation. Finally, scanning electron microscopy demonstrated contact between cells and barrier material and to characterize the fine structure of activated macrophages.

A rapid and marked increase in total peritoneal leukocyte numbers was observed with oxidized regenerated cellulose in contrast to expanded polytetrafluoroethylene or control animals. The principal distinguishing feature was a dramatic shift to activated macrophages with oxidized regenerated cellulose. Activation was confirmed by the adherence assay and morphologic criteria, although the hydrogen peroxide assay showed no difference in capacity to generate reactive oxygen metabolites. The data presented by Dr. Haney provide only partial support for macrophage recruitment as the mechanism by which oxidized regenerated cellulose causes peritoneal damage. Macrophage activation results in numerous functional changes, principally the release of cytokines and the secretion of proteolytic enzymes; those responses were not measured in this study. Furthermore, the authors did not assess a potentially direct toxic effect of either product on peritoneum independently of the inflammatory response. Nor did they evaluate the possibility that either may have an inhibitory effect on tissue fibrinolytic activity. The murine model used in the current work differs from previous animal models where uterine horn scrapings and peritoneal sidewall defects were created and adhesion scores were compared in treated and control animals. For instance, in the rabbit studies of Diamond et al.,[6] oxidized regenerated cellulose application resulted in a 24% reduction in the area of the traumatized sidewall that was found to be involved with adhesions at the time of necropsy. Criticism may be leveled against the current study because it does not approximate the clinical situation where the barrier material is placed over a site of injury. However, Dr. Haney argues convincingly that first it is important to determine the effect of any surgical material on the normal tissues with which it will come in contact. Although it is logical, it does not necessarily follow that a barrier material that injures normal peritoneum will cause more adhesions when it is applied to surgically traumatized peritoneum.

I would like to ask Dr. Haney the following questions:

1. Do you have preliminary data or plans to assess possible direct toxic effects of oxidized regenerated cellulose on explants of peritoneum or in tissue culture? Do you have evidence for inhibition of fibrinolytic activity by either product?
2. Would you comment on any qualitative or quantitative differences between free peritoneal macrophages as studied by you and resident macrophages at the site of injury? Are the free cells representative of the adherent macrophages in terms of enzyme activity or the ability to produce free oxygen radicals?
3. Peritoneal healing is not complete until 5 to 8 days after injury and oxidized regenerated cellulose disappears within 3 days after application. Are these observations compatible with the hypothetic mechanism of action, namely, that it prevents the deposition of fibrin bands and subsequent fibroblast ingrowth?
4. How do you reconcile your observations in the mouse with those of Diamond et al.[6] in the rabbit uterine horn and sidewall defect model? Is this a difference in the methods used to develop adhesions, in the site of application, or in adhesion scoring?

5. On the basis of your experiments, you have stated that oxidized regenerated cellulose is not an ideal material to be used as a surgical barrier to prevent adhesions to peritoneal surfaces. In this context, could you comment on possible limitations of the multicenter clinical trial in which you were a participant? For instance, do you believe that the results of that study justify its extended use at other pelvic sites and in other operative situations?
6. Would you speculate on a possible specific application for expanded polytetrafluoroethylene or a similar material in infertility surgery? Is it possible to reconcile the inherently inflammatory aspects of a biodegradable material with the ability to prevent adhesions?

DR. ALAN H. DE CHERNEY, New Haven, Connecticut. The questions I have, first of all, are regarding expanded polytetrafluoroethylene. Why did he not see any adhesion formation in his expanded polytetrafluoroethylene model in a previous study in regard to suture material? We usually noted that the area where we sutured the expanded polytetrafluoroethylene in place was predisposed to adhesion formation.

Also, I was surprised—and I wondered if he was as well—that this product had the inflammatory response that it did. Although it wasn't equivalent to that of the oxidized regenerated cellulose, it certainly was a marked inflammatory response. We have been led to believe that expanded polytetrafluoroethylene is relatively noninflammatory.

My next question is about mass effect. How much of the effect that you noted was due to the mass of material that was placed in the cavity? We did a study a number of years ago where we showed a marked adhesion effect by putting clips in rabbits. The company that manufactured the clips then brought those clips in and showed that if we made clips the size that we put in rabbits in humans, they would be as tall as I was, and that was the reason that we had a fair amount of adhesions. So how much of this is due to mass effect?

Last, what was his observation at the time the animals were killed as far as adhesion formation was concerned? I wonder because he chose a nonstandard model to look at adhesions. I also wonder whether adhesions were generated in this model.

DR. JOHN A. ROCK, Baltimore, Maryland. As we all know, one of the modifiers in animal models for adhesions studies is the presence of blood in the peritoneal cavity. In your model, one of the important variables that should be addressed when the incision is made and the implant is placed is the amount of blood in the peritoneal cavity. It has been well established that oxidized regenerated cellulose loses its efficacy when it becomes involved with blood clots. Incorrect application is of concern. Once it loses its flat position, it becomes a glob of cellulose. Furthermore, large areas of peritoneal trauma that can occur in reproductive surgery may modify its efficacy.

In the murine mouse model infection is always an issue. This also is a confounding variable. Were some of the experiments complicated by infection? Were the animals covered by antibiotics before the sampling and were the sham controls covered by antibiotics as well?

DR. JOSEPH HILL, Boston, Massachusetts. I have a question about the methods you used. You mentioned that with your study design you did not see an increase in T or B cells. Did you perform any functional assays? I ask because the method you used does not differentiate natural killer cells from macrophage populations, and on the basis of the illustrations you presented, it is possible that some of the cells you are calling macrophages may indeed be either lymphoblasts or natural killer cells.

DR. HANEY (Closing). Dr. Hill has a long-standing interest in T cells, whereas our interest tends to focus on macrophages. I think he's correct. We did not do differential leukocyte counts in these experiments but have done them in other experiments with thioglycollate; these cells are clearly macrophages. I did not repeat the differential counts with this study, and it certainly is a reasonable criticism that some of these cells we're encountering are not all of the monocyte series.

With regard to Dr. Rock's comments about blood, we intentionally used a flank incision that's about 4 mm long and carefully excluded any animals we encountered with significant bleeding at that site. So I do not believe the flank incision for insertion will complicate the question of bleeding because there really was not much.

Infection is a constant concern. We did not treat any animals with antibiotics, sham-operated controls or others. We lost no animals. We saw no animals with cytospins that had polymorphonuclear leukocytes in the peritoneal cavity the way you would anticipate with

infection. We had no cutaneous fistulas. The only comment I can make is that they didn't lose weight and we used no antibiotics and saw no obvious evidence of any infection.

In response to Dr. DeCherney's comments, all I can say is we did not encounter adhesions to the site of the suture. We used 7-0 Prolene sutures and triple knots. I didn't show any, but we have many examples of simply putting sutures in the peritoneal cavities of our control animals and have not had any adhesions to them. The only time we've encountered adhesions at all is in other experiments when we put the suture material higher in the peritoneal cavity on the right side where it can contact the liver. With the constant breathing and the movement of the liver, the edge of the suture will abrade the liver and create an adhesion, but down below the liver edge we've just not encountered adhesions.

Now, we were a bit surprised that the expanded polytetrafluoroethylene surgical membrane activated the cell population and altered the cell number, but I don't think that should have surprised us. It's not invisible to the immune system. Expanded polytetrafluoroethylene may have a very unique or different elicitation response. So, it was a bit of a surprise on the basis of previous information that implanting these materials in solid tissue models does not lead to much inflammation. Again, I think that's the entire reason we were performing the study on the peritoneal fluid cell populations. It's really necessary to put the biomaterial in the site in which it's going to be clinically used and exposed to the immune system in the peritoneal cavity. The reaction is likely to be very different than in solid tissue models.

The mass effect of the material tends to be a frustrating issue to deal with because obviously these are metabolically different animals. The size of the barrier is not out of line with using two or three membranes in relative proportion between the mouse and the human. So, whereas I can never directly address that because these are obviously different animals, I simply think it's a fairly minimal concern.

We did not notice any adhesions when we killed the controls or the expanded polytetrafluoroethylene–treated animals. All I can say is we just didn't encounter them in our experimental study design.

Dr. Novy had several questions. We have not yet done organ cultures taking peritoneum, putting it in tissue culture, and then placing the materials. That's certainly a good idea. We also are planning on doing short-term experiments intraoperatively. I would be extremely surprised if fibrinolytic activity is not depressed by the oxidized regenerated cellulose material because anything that's acidic or generates an inflammatory response tends to depress fibrinolysis. I just don't believe there are any data to address it at the moment and we did not do so in this study.

He also asked whether the cells that cover the injured surface differ from the cells in the peritoneal cavity. In earlier experiments we placed latex beads in the peritoneal cavity so the macrophages present would ingest them. Those are the cells attached to the surface, so realistically I think they're the same cells. The possibility does exist that those cells may be altered by attachment.

He asked about the time course of the study. The rapidity with which this material dissolves is a bit inconsistent with the length of time you would like a barrier present to prevent adhesions. It is degraded extremely rapidly. The differences between these studies and others, notably, the rabbit model, are all going to be difficult to address. You have species differences and model differences. Quite frankly, the reason we chose this model as opposed to the rabbit model is that we wanted another species to look at. We could evaluate the immunologic aspects of it in the peritoneal cavity, and I think most of these materials need evaluation in more than one species to be reasonable.

Now, we participated in a randomized, prospective clinical trial with oxidized regenerated cellulose with one side getting the material and one side not, and then we submitted our data to the company. I have significant concerns about the trial, and they stem from two features. One is the number of patients in the trial. If you considered a 50% adhesion rate and would like to reduce that to 40%, to get a reasonably powerful study, you need about 400 patients per treatment arm. Luckily, with this material, from the company's perspective, one patient is two treatment arms, a control side and a treatment side, but you still are short of what's necessary to have a powerful clinical study.

Second is the issue about the abstruse nature of the scoring system. I'm not sure at all what the area of an adhesion means. An adhesion occurs between two structures. I don't think the area is a significant issue. So I remain very concerned about the validity of that trial, and clearly this material needs to be placed at other sites, on a bleeding surface or bleeding edge of a myomectomy incision or on the ovary, to be able to verify that it's efficacious at those sites. Last is the issue of biodegradability. I remain concerned that any material that's rapidly degraded will not serve this purpose well. The rapidity with which it degrades is directly proportional to its ability to elicit an inflammatory response, and inherently, I think those are in the opposite direction of our intent. So I think we're going to be learning a lot about biomaterials in the future, and that's going to be a critical issue for barrier technology.

Maternal phenylketonuria collaborative study, obstetric aspects and outcome: The first 6 years

OBJECTIVE: The purpose of this study was to evaluate the efficacy of a phenylalanine-restricted diet in reducing fetal morbidity associated with maternal hyperphenylalaninemia in women of childbearing age with blood phenylalanine levels >240 μmol/L (>4 mg/dl) or an unrestricted diet.
STUDY DESIGN: Two hundred thirteen pregnant women with hyperphenylalaninemia that resulted in 134 live births have been enrolled in the study. Outcome measures were subject to the χ^2 test, Fisher exact test analysis of variance, *t* test, or Wilcoxon nonparametric test for analysis.
RESULTS: Optimal fetal outcome appeared to occur when blood phenylalanine levels <600 μmol/L (<10 mg/dl) were achieved by 8 to 10 weeks' gestation and maintained throughout pregnancy (trimester averages of ≤360 μmol/L (≤6 mg/dl)). Initiation of dietary therapy during the third trimester of pregnancy appears to have little beneficial effect on the fetus.
CONCLUSIONS: Preconceptual counseling and early entrance into a prenatal care program is essential in achieving optimal fetal outcome in women with hyperphenylalaninemia. (AM J OBSTET GYNECOL 1992;166:1150-62.)

Key words: Maternal phenylketonuria, fetus, mental retardation, congenital defects, dietary therapy

Phenylketonuria is an inborn error of phenylalanine metabolism that was a major cause of mental retardation.[1, 2] However, routine newborn screening for this disorder and attendant early dietary treatment have virtually eliminated mental retardation from phenylketonuria.[3] In spite of this remarkable achievement, the effort to eliminate mental retardation related to phenylketonuria has progressed through a series of successes and disappointments. Postnatal phenylketonuria-related brain damage has primarily been eradicated; however, in the course of, and to a great extent as a result of, achieving this a previously very rare deleterious effect has emerged, namely fetal damage caused by untreated maternal hyperphenylalaninemia.[4] Thus young women with phenylketonuria in whom mental retardation was prevented by early treatment during infancy and childhood are becoming pregnant and are at high risk for birth defects in their offspring.

Although this problem was identified more than 30 years ago, many questions about the disease process and the treatment of the disorder still remain. To elucidate the problems concerning maternal phenylketonuria, the National Institute of Child Health and Human Development initiated the National Maternal Phenylketonuria Collaborative Study (1984). Subsequently Canada joined this study. Specific questions addressed by the study include: (1) What phenylalanine level during pregnancy will maintain normal fetal development? (2) Is preconceptual phenylalanine restriction necessary? and (3) Is supplementation with tyrosine and various trace elements necessary for normal pregnancy outcome?

The purpose of this article is to present a preliminary report on the obstetric findings of the first 6 years of the study.

Material and methods

Study design. A prospective, longitudinal, observational study was designed by participants in the Col-

laborative Study to evaluate the efficacy of a phenylalanine-restricted diet in reducing fetal morbidity associated with maternal phenylketonuria. The Collaborative Study involves phenylketonuria centers in 50 states, the District of Columbia, Puerto Rico, and all of the provinces in Canada, which are regionally organized under the direction of five contributing centers. The coordinating center located at Children's Hospital of Los Angeles coordinates and maintains relationships with the contributing centers for patient identification, recruitment, outreach, education, enrollment, clinical follow-up, and collection of data, which are collated at a central data bank in Los Angeles. Quarterly evaluations of the project are completed by the coordinating center and are made available to the participating clinics.

Before the initiation of the study institutional review board approval was obtained by the individual participating centers.

Inclusion criteria. The goal of the study, as determined by sample-size calculations, is to include ≥200 hyperphenylalaninemia pregnancies with offspring. Eligibility criteria consist of women of childbearing age whose blood phenylalanine concentration on an unrestricted diet is >240 μmol/L (>4 mg/dl). The subjects must be intellectually capable of understanding and signing an informed consent and willing to comply with dietary treatment and cooperate with the collaborative study staff in providing data. In addition, these women must voluntarily become pregnant at some time during the term of the project. All pregnancy outcomes, including spontaneous and elective terminations, are contained in the study.

There are two groups of control subjects. The first control group, office controls, consists of women without hyperphenylalaninemia enlisted from the same obstetric practice used by a subject with hyperphenylalaninemia. These subjects are matched for race, maternal age, gestation, and parity. The second control group, familial controls, consists of persons selected from either the same sibship of the subject, sibship of the natural father of the offspring of the subject, or first cousin of the subject. All controls are monitored prospectively. Additional comparison groups include (1) historical data from the Lenke-Levy survey of untreated hyperphenylalaninemia pregnancies,[5] (2) earlier untreated pregnancies of the study subjects, and (3) prospective evaluation of the pregnancies of mates of men with hyperphenylalaninemia.

Potential subjects are identified through a variety of sources; clinic records, national and state registries, media public service messages and national, state, and local medical meetings. On meeting study criteria informed consents are signed by all eligible women. Dietary treatment is initiated if indicated.

Subjects enroll and begin receiving treatment at either of two stages relative to pregnancies: before conception of planned pregnancies whenever possible, or after conception on the discovery of an unplanned pregnancy.

Management protocol. The treatment plan consists of providing adequate nutrition during pregnancy, offering a diet restricted in phenylalanine to women with hyperphenylalaninemia with blood phenylalanine concentrations of ≥600 μmol/L (≥10 mg/dl), maintaining blood phenylalanine concentrations between 120 and 600 μmol/L (2 to 10 mg/dl), and supplementing with tyrosine and trace elements as medically indicated.

Patients are treated at their usual phenylketonuria treatment center or at a local medical center on a monthly basis for evaluation and dietary counseling. Weight gain, diet records, and analysis of plasma trace elements and amino acids are evaluated monthly; a weekly blood sample is collected by finger stick for phenylalanine measurement to determine whether alterations in diet therapy are necessary. During a pregnancy, each woman continues to see her private physician for prenatal care. At approximately 20 weeks' gestation ultrasonographic dating of the pregnancy is obtained. Repeat ultrasonographic examinations are performed at 28 and 34 weeks' gestation for fetal evaluation and additional dating information. After delivery all children are monitored and assessed for cognitive and behavioral development.

Study evaluation. All data are collected in a standardized format. Data on maternal and offspring outcomes include the incidence of spontaneous abortion, major complications of pregnancy and delivery, gestational age at delivery, congenital malformations such as microcephaly and heart defects, and offspring growth and development. Additionally, several potentially confounding variables are included in data collection and analysis. Among these are parental intelligence quotient, parental head circumference, socioeconomic status of the parents, overall nutritional status, and exposure to teratogens such as drugs, tobacco, and alcohol. Outcome measures are stratified according to maternal hyperphenylalaninemia classification and the time of onset of treatment.

For the purpose of this report, standard statistical methods for rates and proportions were used in data analysis because many of the end points were dichotomous variables. Simple contingency table analysis was done by χ^2 or the Fisher exact test for comparison between groups on overall proportions and frequency distributions of categoric variables. Continuous variables were analyzed with analysis of variance, the t test, or the Wilcoxon nonparametric test when appropriate. A p value of 0.05 was accepted as significant.

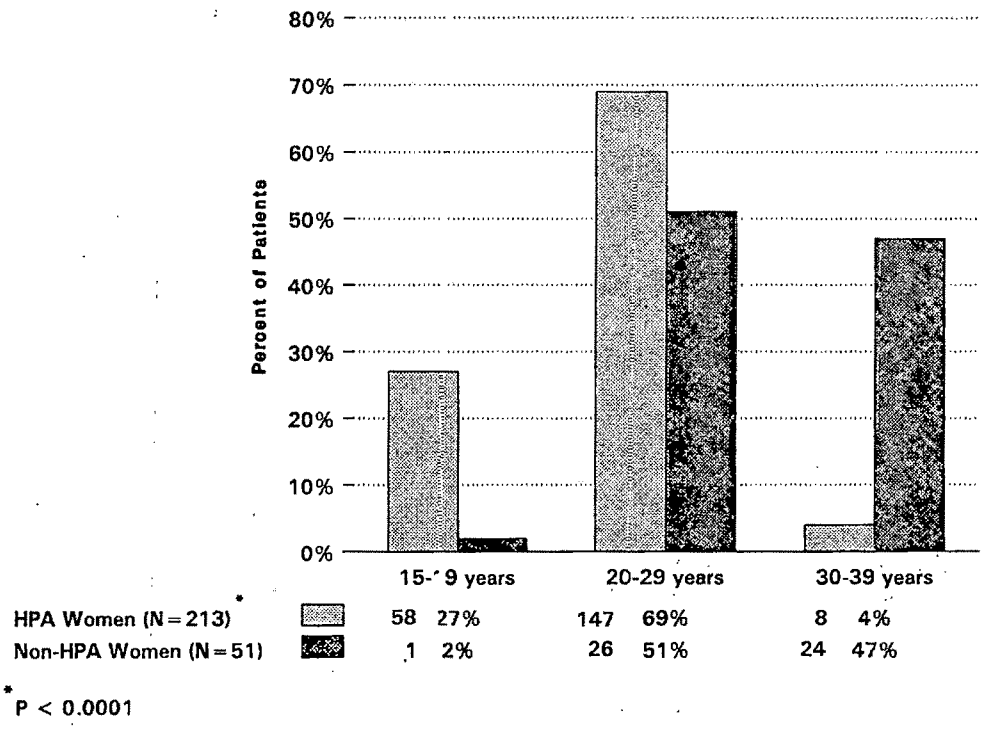

Fig. 1. Maternal age of women in the hyperphenylalaninemia *(HPA)* and control *(Non-HPA)* groups at conception.

Table I. Gestational age at enrollment for hyperphenylalaninemic and control pregnancies

	Hyperphenylalaninemia		*Control*	
	No.	*%*	*No.*	*%*
Preconception	57	27	0	0
0 to 4 Weeks	9	4	2	4
5 to 8 Weeks	59	28	12	24
9 to 13 Weeks	44	20	17	33
Second trimester	40	19	16	31
Third trimester	4	2	4	8
TOTAL	213	100	51	100

Results

A total of 285 women with hyperphenylalaninemia who had 237 pregnancies were enrolled during the first 6 years of the study. Two hundred thirteen of these pregnancies were completed, with 134 live births achieved. Concurrently, 78 pregnancies in the nonhyperphenylalaninemia control groups were entered in the study. The control group consisted of 52 office controls, 8 familial controls, 10 unaffected mothers with previous children affected by a metabolic disorder, and 8 mates of men with phenylketonuria. There were 51 completed pregnancies, all live births, among the office controls. The other groups were not included in the present data analyses because of insufficient sample size.

Comparison of hyperphenylalaninemia and control groups. The gestational age at enrollment for completed pregnancies in the hyperphenylalaninemia and control group is shown in Table I. As expected, none of the controls were entered preconceptually as opposed to 27% of the women with hyperphenylalaninemia. More control women (61%) were enrolled during their first trimester of pregnancy than women with hyperphenylalaninemia (52%).

A comparison of maternal age distribution at the time of conception of the subjects with hyperphenylalaninemia and the control subjects is shown in Fig. 1. The women with hyperphenylalaninemia were found to be significantly younger at the time of conception than the nonhyperphenylalaninemia group ($p < 0.0001$). Twenty-seven percent of the women with hyperphenylalaninemia were between 15 and 19 years old at the time of conception, whereas only 2% of the control women were a similar age when they conceived. Con-

*Percentage of recommended weight for height.

versely, only 4% of the women with hyperphenylalaninemia were between 30 and 39 years old as opposed to 47% of the control group at conception.

Dietary therapy. As indicated in Table II, 19 (9%) of the study subjects were found to have untreated blood phenylalanine levels <600 μmol/L (<10 mg/dl) and were not offered dietary treatment. Thirty-six (17%) of the women with hyperphenylalaninemia were given phenylalanine-restricted diets before conception. Ninety-three (44%) of the women with hyperphenylalaninemia initiated diet therapy in the first trimester of pregnancy, 32 (15%) in the second trimester, and 2 (1%) in the third trimester. Thirty-one (14%) women with hyperphenylalaninemia were enrolled in the study who did not accept treatment at any time during pregnancy.

Maternal weight gain during pregnancy in women with hyperphenylalaninemia and women in the non-hyperphenylalaninemia control group can be seen in Table III. For those women who were the appropriate weight in relation to their height, mean weight gain was observed to be identical in the women with hyperphenylalaninemia and women who were unaffected. There was a tendency for women in the hyperphenylalaninemia group who were <90% of their recommended weight to gain less (23 pounds) than control women (36 pounds) in the same weight classification. Women with hyperphenylalaninemia who were >110% of their recommended weight gained slightly more weight than their control counterparts.

Obstetric history and complications. Obstetric and medical data are listed in Table IV. Significantly more women with hyperphenylalaninemia were primigravid than were controls (34%) ($p = 0.04$). No significant differences were observed in the incidence of smoking and the use of marijuana or other drugs between the groups. Women with hyperphenylalaninemia reported a significantly lower frequency of alcohol consumption than did control women ($p = 0.01$).

The incidences of diabetes, hypertension, or abnormal bleeding were not found to be significantly different between the affected and control groups.

Fetal and postnatal loss. A fetal loss rate of 37% occurred in the hyperphenylalaninemia group (Table V). Of the 79 losses observed, 37 (17% of the total pregnancies) were spontaneous abortions. The rate of spontaneous abortion among women with hyperphenylalaninemia was not different for those 5 (16%) who declined to adhere to the recommended diet compared with the 7 (19%) who began diet therapy before conception (Fig. 2). Women with hyperphenylalaninemia who had blood phenylalanine levels of <600 μmol/L (<10 mg/dl) during their pregnancies and were not offered the restrictive diet had no spontaneous abortions. When stratified by the time diet therapy was initiated the frequency of spontaneous abortion for the

Hyperphenylalaninemia postnatal loss: three deaths from heart defects at ages 2 weeks, 2 weeks, and 22 months. Control postnatal loss: one death related to extreme prematurity. *HPA,* Hyperphenylalaninemia.

women with hyperphenylalaninemia did not significantly alter among these various classes. No fetal wastage was observed in the control group of the study.

Thirty-nine (49%) of the 79 hyperphenylalaninemia pregnancy losses were caused by elective terminations. Twenty-three (59%) of these abortions occurred in the group of women with hyperphenylalaninemia who either refused indicated dietary treatment or planned elective termination at study entry. One (1% of all losses) ectopic pregnancy, terminated at 9 weeks' gestation, occurred in a mother with hyperphenylalaninemia who initiated diet therapy at 4 weeks' gestation. In addition, 2 (3% of all losses) pregnancies resulted in stillbirths, 1 occurring at 25 weeks' gestation, 1 at 36 weeks gestation. Both women began restricted diets between 8 and 13 weeks' gestation.

The hyperphenylalaninemia group of live births resulted in 3 (2%) postnatal losses related to congenital heart defects. One (2%) neonatal loss observed in the control was associated with extreme prematurity.

Delivery outcome. A summary of the delivery outcome of the hyperphenylalaninemia and control pregnancies is listed in Table VI. No statistical difference was observed in a comparison of the hyperphenylalaninemia and control groups for the method of delivery, number of multiple births, sex, and 1- and 5-minute Apgar scores. Significant differences did occur between the two groups, however, in the percentage of infants whose birth measures of length ($p = 0.01$), weight ($p = 0.02$), and head circumference ($p = 0.0001$), were <10th percentile. None of the control pregnancies resulted in newborns with birth measurements <10th percentile; 24% of the hyperphenylalaninemia offspring had abnormally small head circumference, 11% had decreased weight, and 11% had decreased length.

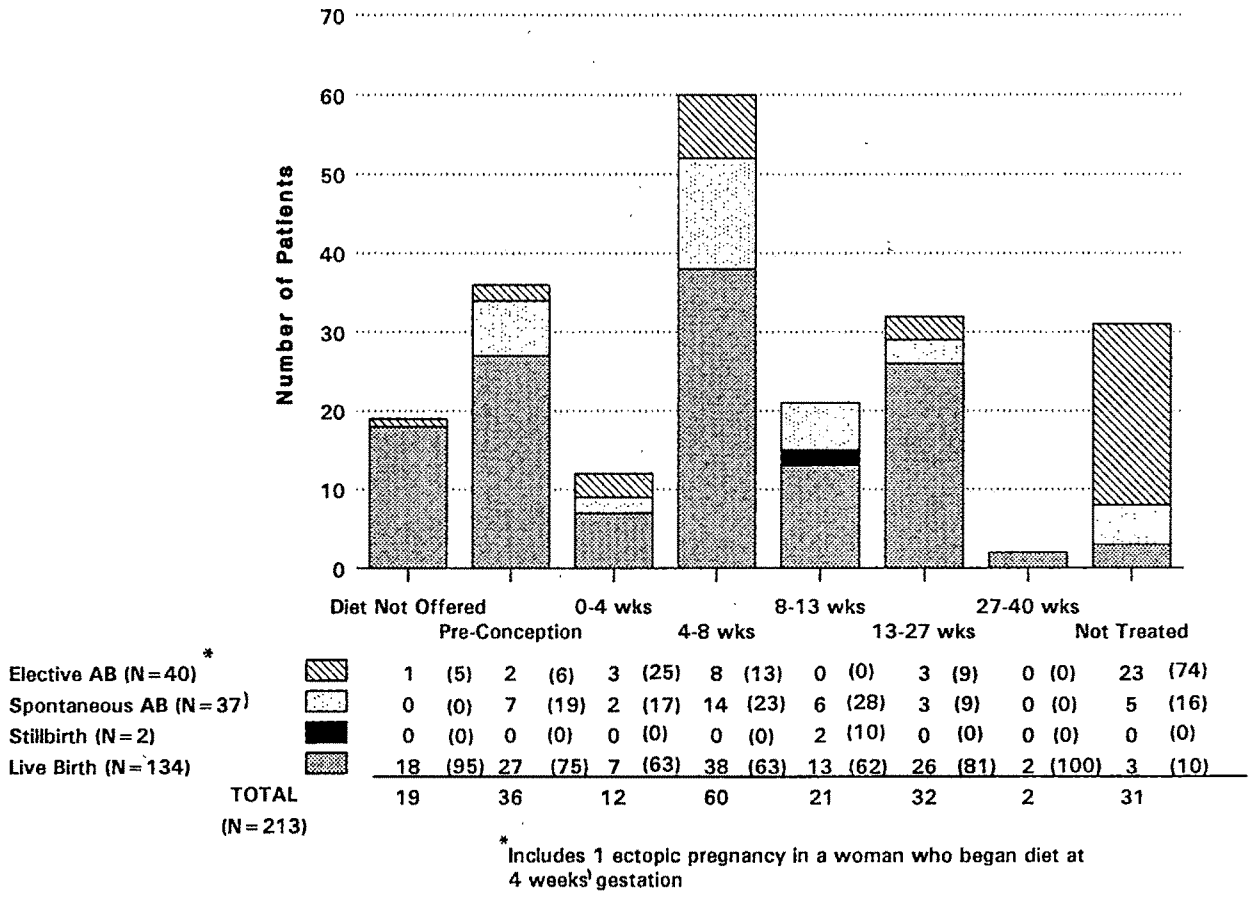

Fig. 2. Pregnancy outcome in patients with hyperphenylalaninemia stratified by gestational age at initiation of diet during pregnancy. *AB*, Abortion; ( ), percentage of total.

The dose-related effects of phenylalanine on fetal growth can be seen in Fig. 3, which illustrates the median birth measurement percentiles by gestational age at which maternal blood phenylalanine levels <600 μmol/L (<10 mg/dl) were achieved. Although notable differences in length and weight can be recognized in the offspring of those women who did not achieve dietary control until >10 weeks' gestation, head circumference was most severely affected.

Birth measures of the offspring were also analyzed according to the effects of maternal smoking on birth length, weight, and head circumference <10th percentile (Table VII). A statistically significant difference was observed only for head circumference ($p = 0.046$) in those women with hyperphenylalaninemia who had a positive history of smoking.

Congenital malformations. Congenital malformations observed at birth in the hyperphenylalaninemia population are arranged in Table VIII according to the patients' average blood phenylalanine levels for any trimester of pregnancy.

The presence of microcephaly was noted if diagnosed at birth. Ninety percent[27] of the women with hyperphenylalaninemia with phenylalanine levels of ≥1200 μmol/L (≥20 mg/dl) had microcephalic infants. Those women who had levels between 600 and <1200 μmol/L (10.1 to 19.9 mg/dl) had a 49% (19 infants) incidence of microcephaly. None of the infants born to women with hyperphenylalaninemia whose levels were ≤600 μmol/L (≤10 mg/dl) throughout pregnancy had microcephalia.

Intrauterine growth retardation is defined here as birth weight, length, *and* head circumference below the third percentile. Similar to the observations made with microcephaly, 27 (90%) of the affected subjects with phenylalanine levels of ≥1200 μmol/L (≥20 mg/dl) were found to have intrauterine growth retardation. A decrease in the incidence of the disorder was observed with a decrease in blood levels. Four (10%) of women with hyperphenylalaninemia with intermediate blood levels had intrauterine growth retardation infants. None of the offspring of the women with levels of ≤600 μmol/L (≤10 mg/dl) were abnormally small.

Six congenital heart defects were identified only in

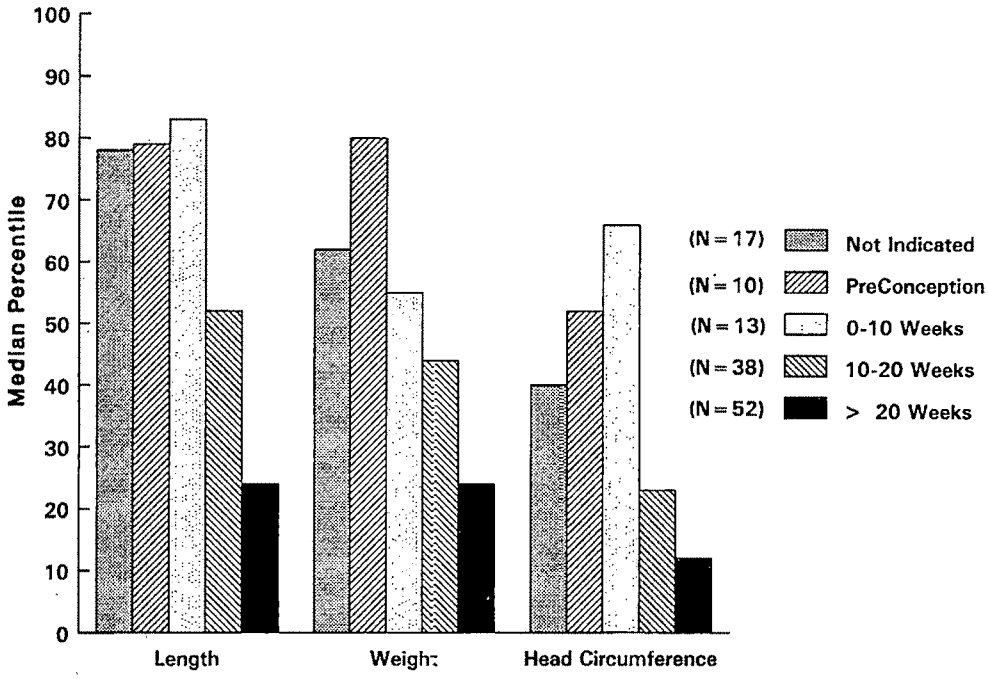

Fig. 3. Median birth measurement percentiles by gestational age at which maternal blood phenylalanine level <600 μmol/L (<10 mg/dl) was achieved.

women whose phenylalanine levels were >500 μmol/L (>10 mg/dl). The cardiac defects observed included ventricular septal defect, hypoplastic left ventricle, coarctation of the aorta, and tetralogy of Fallot. None of the women with hyperphenylalaninemia whose levels were ≤600 μmol/L (≤10 mg/dl) had infants with cardiac defects.

For this report, facial dysmorphism is defined as infants who had one or more abnormal facial features in an infant. Abnormal facial appearance included features such as epicanthal folds, prominent ears, long philtrum, upturned nose, micrognathia, and wide, depressed nasal bridge. The majority of infants born to affected mothers with hyperphenylalaninemia at all phenylalanine blood levels were noted to have at least one dysmorphic feature. The highest incidence (97%, 29 infants) was noted in women with phenylalanine levels ≥1200 μmol/L (≥20 mg/dl). The frequency of

this disorder decreased in relation to a decrease in blood levels. Ninety-two percent (36 infants) and 88% (28 infants) of infants with mothers having intermediate and low blood levels, respectively, were found to have dysmorphic facies.

A number of minor anomalies were noted in the entire affected population regardless of the maternal blood phenylalanine concentration. These included 2 infants with inguinal hernias, 3 with undescended testes, 3 with hypospadias, 2 with club feet, 1 with syndactyly, and 1 with a renal anomaly: a duplicated collection system.

Comment

The success of dietary therapy in arresting the neurologic deficits caused by hyperphenylalaninemia has inadvertently produced an increasing number of non-hyperphenylalaninemia mentally retarded offspring. Currently there are >1600 known and tracked women with hyperphenylalaninemia in the United States and Canada who are of childbearing age. Taking into account the numbers of unknown women with hyperphenylalaninemia, including those born before newborn screening for phenylketonuria or who immigrated to the United States from countries with no newborn screening, conservative estimates have suggested that there may be 5500 fecund women with hyperphenylalaninemia in the United States who are at risk of giving birth to an affected offspring.[6] The possibility has been raised that after only one generation, given average reproductive rates, the incidence of phenylketonuria-related mental retardation could return to the level existent before national screening and treatment.[7] The threat of this problem has thus demanded

a large, well-designed, well-controlled investigation of the problem and its potential prevention, such as that developed by the National Maternal Phenylketonuria Collaborative Study. This study is especially unique in that, to ensure its success, it has required the active participation a large number of individual institutions and the cooperative efforts of a multidisciplinary medical team that includes obstetricians. With the advancement of dietary therapy phenylketonuria has routinely been categorized as a medical disorder of children, the treatment of which has interwoven the efforts of pediatricians, nutritionists, psychologists, and public health personnel. Obstetric contributions regarding this disorder have been notably limited. However, with the recognition of the teratogenic effects on the fetus and related interventions, the need for increased involvement by the obstetrics community in maternal phenylketonuria is clearly evident. One of the goals of this report is to alert the maternal-fetal medical community of the identification, antenatal and intrapartum effects, and treatment of this disorder.

Approximately two thirds of the anticipated enrollment of subjects with hyperphenylalaninemia into the Collaborative Study has been achieved. It is anticipated that the enlistment phase of the study will continue until the end of 1994 to achieve the desired sample of 200 mother-infant dyads. Although definitive conclusions concerning this investigation are forthcoming, early analyses of the available data as presented in this preliminary report suggest several findings and considerations.

As indicated by the results of this study, dietary control is essential for optimal pregnancy outcome. An important consideration in dietary management is the provision of proper nutrition to ensure an adequate maternal weight gain for normal fetal growth and development. The mean weight gain of the women with hyperphenylalaninemia demonstrated that affected women achieved their recommended weight during pregnancy and maintained a strict phenylalanine-restricted diet. However, the lowest weight gain was seen in women who were preconceptually <90% of the recommended weight for their height. Further analysis of the data is needed to determine whether the incidence of intrauterine growth retardation is related to inadequate weight gain in this specific weight class.

Observations of the occurrence of congenital malformations have indicated that a minimal teratogenic effect of hyperphenylalaninemia occurred when maternal blood phenylalanine levels were maintained at <600 μmol/L (10 mg/dl) for all three trimesters of pregnancy. Comparison of the current data with an international review of women with untreated hyperphenylalaninemia[5] confirms the importance of maintaining minimal blood phenylalanine levels. The incidence of microcephaly was found not to be significantly different between the treated and the historic untreated populations for phenylalanine levels of ≥1200 μmol/L (≥20 mg/dl) and levels between 600 and <1200 μmol/L (10.1 to 19.9 mg/dl). The treated hyperphenylalaninemia pregnancies of the current study with blood levels <600 μmol/L (<10 mg/dl) did have a significantly ($p = 0.007$) lower incidence of microcephaly than the untreated patients in the historic study. In terms of the occurrence of congenital heart defects, however, no significant differences were noted in any classification of phenylalanine blood levels when comparisons were made between the two studies. Because the desired population size has not yet been achieved, it is premature to say whether this is a valid observation or a statistical β error.

Initiating diet therapy during the third trimester of pregnancy appears to have minimal effect on fetal outcome. As indicated in the observations made on birth measurements, optimal treatment levels (<600 μmol/L (<10 mg/dl)) should be achieved by 8 to 10 weeks' gestation, with trimester levels averaging ≤360 μmol/L (≤6 mg/dl). Dose-related effects of phenylalanine could be observed in the higher incidence of birth length, weight, and particularly head circumference at <10th percentile in women with hyperphenylalaninemia who were not well controlled during pregnancy.

A further finding that appears to have a variation of effect dependent on phenylalanine level is facial dysmorphism. Study findings continue to demonstrate an increasing incidence of dysmorphic features with increasing maternal phenylalanine blood levels as initially reported by Rouse et al.[8] A similar incidence of dysmorphic facies has been reported by Lipson et al.,[9] who attribute the facial appearance of offspring with hyperphenylalaninemia to facial bone hypoplasia.

The women with hyperphenylalaninemia had a higher incidence of fetal loss than the control group. Although the frequency of spontaneous abortion (17%) in the hyperphenylalaninemia group appears to be excessive in comparison with no loss in the control women, the lower incidence of spontaneous abortion in the control group could be attributed to sampling differences. Only 4% of the control population, as compared with 31% of the hyperphenylalaninemia group, were enrolled in the study by 4 weeks' gestation, a period normally associated with a significant rate of early, often undetected, abortion.[10] Even without this consideration, the spontaneous abortion rate of 17% in the hyperphenylalaninemia group may well be within the limits of the average spontaneous loss rate of 40% in some populations.[10-12] Further, there was no appreciable difference noted in a comparison of the incidence of elective termination of the study population (19%) and the general population (33%).[13]

The relatively young age of the women with hyperphenylalaninemia at enrollment in the study is not an unexpected finding. National newborn screening for phenylketonuria was instituted in Canada and most of

the United States by 1965. The first generation of identified and treated infants with phenylketonuria, now between the ages of 15 and 25 years, was targeted for this study. Obstetric management of the hyperphenylalaninemia-affected group between the ages of 15 and 19 years, representing 27% of the sample, presented a number of challenges. Pregnancies in very young women have been reported to have an increased incidence of antenatal and intrapartum complications. However, the preliminary results of the study do not demonstrate an increase of high risk obstetric conditions in the hyperphenylalaninemia group when compared with the older control group.

A further consideration in this younger sample is the incidence of sexual activity. A number of surveys of women between the ages of 15 and 19 years have shown this age group to be sexually active with limited use of birth control.[14, 15] It has been reported that 42% of all never-married 15- to 19-year-old adolescent girls have experienced sexual intercourse, with two thirds either inconsistently or never using some form of contraception.[15] A recent report by Waisbren et al.[16] concluded that sexual activity among adolescents and young women with phenylketonuria was comparable with that of their acquaintances who did not have phenylketonuria and with young women with diabetes, thus emphasizing the risks for pregnancy in this population. These statistics, in conjunction with the hazards of maternal phenylketonuria syndrome, indicate the importance of education in the hyperphenylalaninemia population. Known patients with hyperphenylalaninemia should be counseled about dietary control, the possible consequences of pregnancy, and available methods of birth control. Nevertheless, they are not more fastidious in the use of conventional birth control than their peers.[16] Consequently it seems reasonable to consider the use of the new, long-lasting subdermal implant, Norplant (levonorgestrel). Norplant has been shown to be effective for up to 5 years after implantation, with a reported pregnancy rate of <1%.[17] The effectiveness and convenience of Norplant make it an ideal method of birth control for the younger group of women with hyperphenylalaninemia. It may also be an ideal contraceptive device for older women with hyperphenylalaninemia of childbearing age who were born before newborn screening and treatment and may be intellectually impaired.

Preconceptual education of women with hyperphenylalaninemia should also include information concerning the risks of tobacco use during pregnancy. Although studies have previously documented an increased incidence of low-birth-weight infants in women without hyperphenylalaninemia who smoked during pregnancy, maternal smoking appears to be especially hazardous in hyperphenylalaninemia women. The hyperphenylalaninemia study population who had infants with head circumferences <10th percentile had a significantly increased history of smoking. Thus it appears that maternal smoking provides a compounding effect in a population already at risk for infants with a decreased head size. Further investigation of this issue will be required.

The preliminary obstetric findings of the study suggest that the teratogenic effects of hyperphenylalaninemia can be avoided with preconceptual or early gestational dietary control maintained throughout pregnancy. Although dietary therapy is essential in the management of maternal phenylketonuria, it is of little benefit to undiagnosed women with hyperphenylalaninemia. Newborn screening has determined the incidence of phenylketonuria is about 1 in 15,000 and has led to the identification of phenylketonuria in most women under the age of 25 years. However, Hanley et al.[18] have estimated that the incidence of undiagnosed maternal phenylketonuria is about 1 in 30,000. The majority of women with undiagnosed phenylketonuria were born before the initiation of newborn screening. Also included in these numbers are women previously diagnosed with phenylketonuria who have been lost to medical follow-up and women with phenylketonuria who have emigrated from countries without a newborn-screening program.[18] Elimination of the devastating congenital effects associated with maternal phenylketonuria is not possible until all women with phenylketonuria are identified and treated. Several strategies to accomplish this task have been recommended. Among these are the establishment of a national phenylketonuria registry in association with newborn-screening laboratories to keep updated records on patients with phenylketonuria.[19-21] Various phenylketonuria rescreening programs have also been suggested. At a minimum, screening should be performed with any woman who has had a mentally retarded or microcephalic child.[18, 22] Further, screening programs could be initiated at family planning clinics and prenatal clinics[23] with a cost-effectiveness that could approach that in routine newborn screening.[21]

The results of this study are preliminary and further study is ongoing. These data demonstrate the importance of preconceptual counseling and early entrance into a prenatal care program to reduce the incidence of congenital malformations and developmental disabilities in the offspring of women affected by hyperphenylalaninemia.

Discussion

Dr. Joe Leigh Simpson, Memphis, Tennessee (Fellow). A vexing problem in human genetics and obstetrics is that of pregnancy in women with hyperphenylalaninemia or phenylketonuria who were treated in childhood but who stopped their diets when they became adolescents or adults. For over a decade it has been recognized that offspring of such individuals are at increased risk for abnormal development. To address this, a collaborative effort involving most phenylketonuria centers in the United States has been underway since 1984. Dr. Platt has been pivotal to this effort, as is evident by his peers selecting him to present this preliminary report on the obstetric outcome of subjects recruited during the first 6 years of the study.

The project is certainly a daunting one. Phenylketonuria is rare; therefore, the task of identifying a sufficient sample of individuals with phenylketonuria who become pregnant is formidable. Yet we have heard excellent data. Optimal fetal outcome was observed where maternal phenylalanine levels were <10 mg/dl by 8 to 10 weeks' gestation. In microcephaly a dose response curve was observed; with respect to phenylalanine levels, all six cardiac anomalies occurred in women whose levels were >10 mg/dl.

I have a few comments about which Dr. Platt's thoughts would be appreciated:

Comparability. Given the enormous amount of effort expended in recruiting the subjects with phenylketonuria, it is disappointing that comparable effort did not go into the controls. Only 70 controls have been identified: 52 office controls, 8 familial controls, and 10 heterozygous mothers. In aggregate, these women produced 51 completed pregnancies. Moreover, there were substantial differences between the controls and subjects with respect to maternal age and exposure to alcohol and cigarettes.

An indication of the problem with controls is that "no fetal wastage was observed in the control group of the study." Naturally the difference between the phenylketonuria and control groups was statistically significant ($p = 0.0002$). Yet the authors themselves note in their Comment that the comparison is invalid. Weeks of observations are different in the phenylketonuria group and controls, fewer in the latter. The proper way to analyze fetal wastage would involve a life-table approach that would take into account the differing numbers of weeks of observations in the two groups.

Given that this study is ongoing, I hope that greater effort can go into recruiting controls. Perhaps sisters-in-law could be more aggressively sought; of course, recruiting unaffected sisters would have the advantage of observing outcome in more heterozygotes.

Assessment of anomalies. I was puzzled by the higher cardiac anomaly rate (5 of 39, 13%) in women whose phenylalanine levels were 10.1 to 19.9 mg/dl than in those with levels >20 mg/dl (1 of 30 or 3%).

Perhaps this anomaly reflects the trimester in which phenylalanine was measured, which would bear on organ systems that complete development by 12 weeks. Specifically, congenital heart disease should be correlated only with first trimester values. Were they?

Another difficulty relates to assessing facial dysmorphism and minor anomalies. In my opinion there are nearly insurmountable problems in assessing these in collaborative studies because there are few consensus definitions for such semiquantitative anomalies. Some

assurance concerning unbiased assessment of facial dysmorphism would also be nice. That is, was the examination done by an observer unaware of the phenylalanine level? If not, the observer might search more vigorously for anomalies in hyperphenylalaninemia subjects.

Health care delivery problems. I would appreciate the authors' opinion about the responsibility of the patients with phenylketonuria for their own care. We worry that patients with phenylketonuria are not being followed up, and contemplate organizing rescreening programs for that purpose. Yet surely the patients (who had to be intelligent enough to sign a probably complicated informed consent) were aware that they had phenylketonuria as children. (Incidentally, the selection bias of excluding patients with lower intelligence quotients is a general concern.) Surely women with phenylketonuria could not have forgotten the terrible phenylalanine-free diet. Why, then, was not a primary care physician aware of the history before pregnancy? I understand the concept of denial but submit there *is* a patient responsibility. Without such I would be very pessimistic about decreasing anomalies in offspring of mothers with phenylketonuria. After all, genetic screening programs in the nonpregnant adult population have not universally met with rousing success. What is the authors' opinion about the impact and likely success of a system of continued tracing, to say nothing of success of reimplementing diets? A related question is whether they would treat mild phenylketonuria patients who never required treatment during childhood.

In conclusion, I feel privileged to have an opportunity to discuss this long-awaited study by a physician who has contributed greatly not just to ultrasonography but to other important obstetric areas. My disappointment with the control group and other minor concerns do not diminish my general enthusiasm for the major effort presented here.

Dr. Allan P. Killam, Durham, North Carolina. There has been a controversy about NutraSweet sweetener that breaks down into phenylalanine and methyl alcohol. An investigator said in the press that to switch to diet drinks as opposed to regular drinks might expose women with phenylketonuria or even carriers of phenylketonuria to greater incidence of mental retardation in their children.

The makers of NutraSweet sweetener have countered that the amount of phenylalanine in a diet drink is minuscule compared with a banana, a glass of milk, or a hamburger and that this is not a cause of a concern for people with misdiagnosed or undiagnosed phenylketonuria or carriers.

I just wanted to know what is the order of magnitude of phenylalanine in diet drinks, and does this worry that the Centers for Disease Control has promulgated have any basis in science.

Dr. Rudy E. Sabbagha, Chicago, Illinois. How severe was the microcephaly? Usually we make a distinction as to whether head size is 2 SDs below the mean and really not associated with severe future adverse outcome or whether head size is in the range of 3 to 5 SDs below the mean.

Sometimes in ultrasonography we have difficulty diagnosing microcephaly at 28 weeks' gestation. Were these diagnoses made after or before 28 weeks, and how many of the cardiac defects were diagnosed antenatally?

Dr. Robert C. Cefalo, Chapel Hill, North Carolina. How did you control for supplementation for the patients with hyperphenylalaninemia?

Dr. Platt (Closing). Dr. Simpson's question deals with the comparability of the patients with phenylketonuria with the controls and the problems that we had. I believe that during the course of my presentation I, too, illustrated the problems we had with the controls. Since our last review of the entire study we have undertaken a greater emphasis to enroll appropriate controls so that we would have a comparable group at the end of the recruitment of 200 patients with phenylketonuria. This includes using sister cohorts as you have suggested, which we also think is a very good idea.

In terms of our anomaly assessment and interpretation, I think your observations regarding congenital heart disease are also correct. It does appear to be a trimester-related phenomenon in which ongoing changes occur that may not be reflected or seen until later. Clearly, if there is going to be an impact in the reduction of problems such as congenital heart disease, it has to occur early in the first trimester. The number of cases thus far with congenital heart disease is too small to tell whether there is a dose relationship week by week of pregnancy. I hope that by the time we reach our desired sample size of 200 we will have better information with regard to levels and early pregnancy.

In terms of fetal dysmorphism, first let me tell you that all measurements were made without anybody being aware of either the mean phenylalanine levels or the highest peak levels. All data were recorded on a particular code sheet in the cooperating centers and sent to one of the investigators, Dr. Bobbye Rouse, for the formal analysis of the presence of fetal dysmorphism. I think it is quite clear that the effect of some of these changes are clearly related to phenylketonuria. This is not different for other syndromes such as fetal alcohol. I guess it is in the eyes of the beholder.

In terms of the impact on health care and the problems seen with phenylketonuria, I believe there are some sixteen hundred known women with phenylketonuria today whom we are aware of through the various pediatric metabolic centers that monitor these women. There may be >5000 women who may also have hyperphenylalaninemia who may not have been screened earlier or who now have higher levels. The impact here is on education. Some of the patients who get pregnant are seen by primary care providers who are certainly not as aware of the hazards of phenylketonuria because they do not see this disorder in their practices very often. None of these women were seen in study centers; some were seen 200 miles away from the centers to which they had been referred for certain

parts of their treatment. The primary care providers in some instances had very, very little knowledge of phenylketonuria and were unaware of it until the patient, sometime later in the pregnancy, informed them of it. The care provider then got in contact with the centers. With increasing education and by exposure to our obstetric literature one of the problems of the collaborating centers may be alleviated.

As to Dr. Killam's question about NutraSweet sweetener, I think normal patients are at no great risk. On the other hand, in undiagnosed hyperphenylalaninemic women there certainly is a risk. This argument would be the basis for a study to look at a selected population group, perhaps women who have recently moved to the United States in areas such as Los Angeles who have not previously been screened. These women would be studied to determine the impact of substances such as NutraSweet sweetener on their phenylalanine levels.

With regard to Dr. Sabbagha's questions about microcephaly and the timing of diagnosis, some of the cases were clearly diagnosed in utero. We have previously recognized the difficulty in diagnosing microcephaly early in pregnancy. In the newborn 2 SDs below the mean were used as the definition for this study. I would agree with you that we have to wait for more obvious signs, even 3 SDs in the in utero period, because they do not often show themselves till after 28 weeks' gestation. In terms of the cardiac malformations, half of the defects were picked up. The other half were missed. I do not think that that is surprising. It is probably a very good yield considering where all these patients have come from.

Dr. Cefalo's question was how we controlled for vitamin nutrients. Every patient entered in the study underwent counseling with nutritionists who were very much involved in this particular program.

Postmenopausal steroid replacement with micronized dehydroepiandrosterone: Preliminary oral bioavailability and dose proportionality studies

John E. Buster, MD,[a] Peter R. Casson, MD,[a] Arthur B. Straughn, PharmD,[b] Debra Dale, RN,[a] Edward S. Umstot, MS,[a] Neil Chiamori, PhD,[c] and Guy E. Abraham, MD[d]

Memphis, Tennessee, and Santa Monica and Torrance, California

OBJECTIVES: Because dehydroepiandrosterone may protect against neoplasia, osteoporosis, and cardiac disease, we investigated the bioavailability of oral micronized dehydroepiandrosterone, anticipating its adjunctive use in postmenopausal steroid replacement.

STUDY DESIGN: Eight postmenopausal women randomly received either a placebo or 150 or 300 mg of oral micronized dehydroepiandrosterone in a lipid matrix. Serum dehydroepiandrosterone, dehydroepiandrosterone sulfate, testosterone, and estradiol were measured periodically over the 12 hours after each dose. All treatments, all doses, and mean serum dehydroepiandrosterone, dehydroepiandrosterone sulfate, and testosterone were compared with analysis of variance for repeated measures and Newman-Keuls a posteriori test of statistical significance.

RESULTS: Mean peak steroid concentrations after 150 mg (300 mg) doses were dehydroepiandrosterone 1617 (2639) ng/dl, 7 (11.5)-fold above placebo; dehydroepiandrosterone S 1185 (1688) μg/dl, 14 (20)-fold above placebo; and testosterone 183 (311) ng/dl, 4 (7)-fold above placebo. Estradiol concentrations remained <20 pg/ml, but androgen concentrations rose by 1 hour and remained elevated through the twelfth hour. Peak androgen concentrations and areas under the curves exhibited proportionality with both doses. A testosterone radioimmunoassay with celite chromatography revealed a 300% overestimation for testosterone in the direct-assay method used in this study. Thus after appropriate readjustment maximum testosterone concentrations were observed consistently within physiologic premenopausal ranges after the 150 mg dose.

CONCLUSIONS: Micronized dehydroepiandrosterone may provide a steroidal postmenopausal replacement that is adjunctive to estrogens and worthy of further investigation. (AM J OBSTET GYNECOL 1992;166:1163-70.)

Key words: Dehydroepiandrosterone, menopause, replacement, micronized dehydroepiandrosterone

Dehydroepiandrosterone (DHEA) and its sulfated conjugate dehydroepiandrosterone sulfate (DHEAS) are weak androgens secreted by the adrenal cortex in amounts exceeding cortisol.[1] In both men and women production of DHEA and DHEAS rises sharply before puberty and peaks between 20 and 30 years of age independent of cortisol.[2] DHEA DHEAS production and adrenal corticotropin responsiveness decline with advancing age.[3] Ovarian failure at any age accelerates this decline.[4, 5]

Because DHEA and DHEAS were previously considered to be relatively inert circulating adrenal steroidogenic intermediates, the implications of a putative adrenopause were ignored. An increasing body of literature, however, in both human subjects and experimental animals, indicates that physiologic DHEA may protect against neoplasia,[6-8] enhance insulin action,[9, 10] protect against osteoporosis,[11-13] increase immune system competence,[14, 15] and offer (at least in men) cardiac protection.[16] Furthermore, pharmacologic DHEA may exert salutary effects on serum lipoprotein profiles, muscle mass, and body fat percentage in young men.[17] Given the impact of these observations on the quality of postmenopausal life, investigation of DHEA as a possible steroid replacement is timely.

Endogenous DHEA and DHEAS production and conversion contribute modestly to the pool of circulating biologically active androgens and estrogens in women after menopause.[18] With pharmacologic DHEA, however, immediate substantial increases in circulating testosterone and dihydrotestosterone are ob-

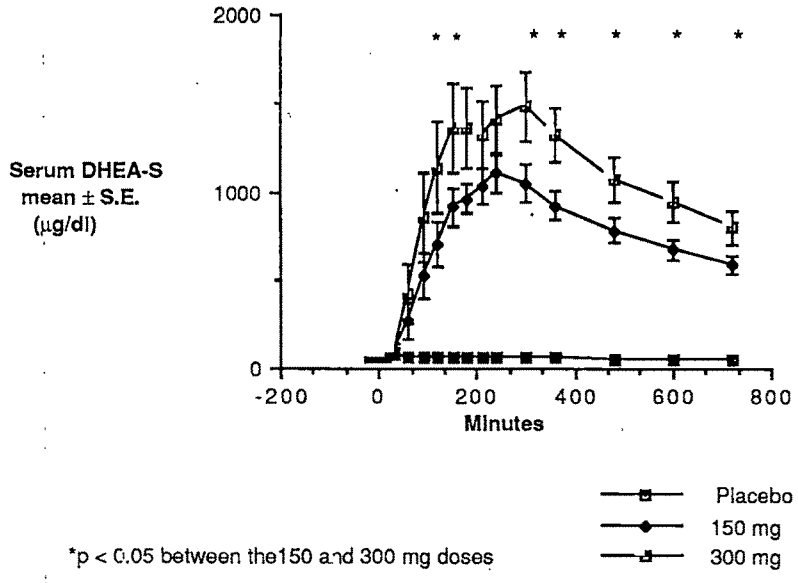

Fig. 1. Mean serum DHEAS concentrations after oral administration of placebo or 150 or 300 mg of micronized DHEA (n = 8).

Table I. Pertinent screening data on subjects (n = 8) enrolled in protocol

Parameter	*Mean*	*Range*
Age (yr)	60	48 to 69
Weight (lb)	138	131 to 151

DHEAS (μg/dl)	55	9 to 11
Morning cortisol (μg/dl)	14	8.4 to 22

served, with estrone and estradiol increasing modestly after 2 to 4 weeks of chronic administration.[19] If there were a reliable method of delivering DHEA at replacement levels, postmenopausal administration of this hormone would be an attractive adjunct to estrogen replacement. Our study investigates replacement doses of oral micronized DHEA delivered in a lipid matrix as a potential strategy directed toward this goal.

Material and methods

With institutional review board approval, eight postmenopausal women were recruited for this study. Medical histories and physical examinations, complete blood cell count, liver, renal, and thyroid function tests, and fasting serum insulin, cortisol, testosterone, and DHEAS concentrations were completed for all eight women. Liver function tests were repeated on completion of the study. Table I lists screening data for the eight participants. Inclusion criteria included body weight between 80% and 120% of the ideal defined by the Metropolitan Life tabular method and at least 6 months of amenorrhea with menopausal symptoms. Any subjects with <1 year of amenorrhea had menopausal status reconfirmed by follice-stimulating hormone >40 mIU/ml. Subjects were either receiving no estrogen replacement therapy (n = 6) or had stopped taking replacement estrogens for at least 2 weeks before and for the duration of the study (n = 2). None smoked cigarettes or took other medication.

The eight subjects were randomly allocated to receive 150 or 300 mg of micronized DHEA or a placebo tablet of identical formulation, each in succession separated by ≥1 week between treatments. Pharmacopeia-grade DHEA (Sigma Chemical, St. Louis) was micronized to <10 μm particles in 90% of the particles examined. The micronized DHEA was mixed with a wax vegetable oil matrix and compressed with a silica-based excipient into a tablet containing 150 mg DHEA (Belmar Pharmacy, Lakewood, Colo.). The patients were fasting when they were admitted to the University of Tennessee, Memphis, Clinical Research Center at 10:00 AM; at that time a heparin lock flush solution was intravenously established in an antecubital vein. DHEA or placebo doses were administered at time 0, and blood samples were drawn at −20, −5, 15, 30, 60, 90, 120, 150, 180, 240, 300, 360, 480, and 720 minutes. Each patient had a light standard meal after 120 minutes if desired. Serum was separated and stored for assay for DHEA, DHEAS, testosterone, and estradiol.

Testosterone and DHEAS concentrations were measured with commercial kits that assay directly with iodine 125–label (Pantex Ltd., Santa Monica, Calif.). DHEA was measured by a commercial tritiated extrac-

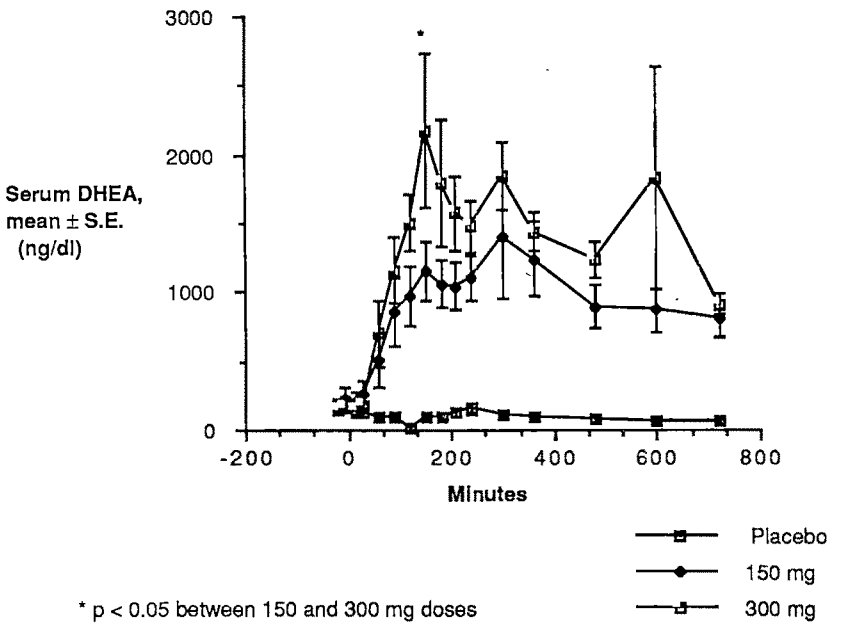

Fig. 2. Mean serum DHEA concentrations after oral administration of placebo or 150 or 300 mg, of micronized DHEA (n = 8).

tion assay (Wein Scientific, Succasunna, N.J.). The interassay variation of the DHEAS, DHEA, and testosterone assays was 8%, 6.5%, 9%, and 8.5%, respectively. The specificity of the testosterone assay was further evaluated by taking a selection of 24 samples from this study with a wide range of testosterone values and reassaying after using a tritiated method, including a preparatory celite chromatography step as described previously.[20] Estradiol was measured by a tritiated radioimmunoaassay with preparatory celite chromatography.[20, 21]

At all time intervals, treatments, and doses mean serum DHEA, DHEAS, and testosterone were compared with analysis of variance for repeated measures and Newman-Keuls a posteriori tests of statistical significance. Peak serum concentrations of all three steroids obtained with each treatment arm were identified, and the mean values were determined. The mean peak values were compared for each steroid and for each treatment arm by the same tests of statistical significance. For each treatment arm for each subject, the area under the serum concentration-time curve for DHEA, DHEAS, and testosterone was calculated by the method of summative trapezoids. Areas under the serum concentration-time curve were derived from all time-concentration curves for the eight patients, and the mean areas under the serum concentration-time curve were calculated. These were then compared statistically within each of the three steroid measurements and between the doses given. The DHEA dose proportionality was determined by comparing areas under the serum concentration-time curve for each steroid and mean peak levels against dose. If the resulting plot was relatively linear, dose proportionality was said to exist. All statistics were done using a statistical software package (Statistical Analysis Systems, Inc., Cary, N.C.).

Results

Mean concentrations of DHEA, DHEAS, and testosterone over the 12 hours after administration of the two micronized DHEA doses or the placebo tablet are presented in Figs. 1 through 3. For all steroids significantly increased levels are seen 1 hour after administration of the DHEA except for estradiol. The estradiol level was <20 pg/ml in 24 samples tested, corresponding to both baseline and highest androgen levels. Furthermore, estradiol showed no systematic increase in concentration within these low ranges. Peak androgen levels were seen 3 to 5 hours after administration.

Mean peak concentration for each steroid for each subject and each treatment is listed in Table II. Similarly, Table III lists the mean of the areas under the serum concentration-time curve for each patient for each steroid as achieved with each of the three treatments. Mean peak concentrations for each of these steroids at 150 mg (300 mg) doses were DHEA 1617 (2639) ng/dl, 7 (11.5)-fold above placebo; DHEAS 1185 (1688) μg/dl, 14 (20)-fold above placebo; and testosterone 183 (311) ng/dl, 4 (7)-fold above placebo. Significant differences existed between peak concentrations of DHEAS, DHEA, and testosterone attained with placebo versus both DHEA doses. Significant differences also existed between the DHEAS and testosterone peaks attained with the two-dose formulations. A sim-

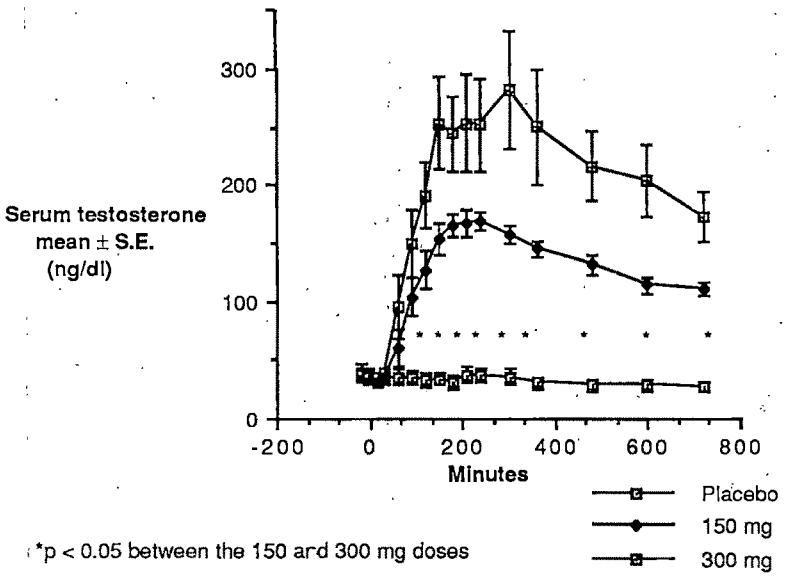

Fig. 3. Mean serum testosterone concentrations after oral administration of placebo or 150 or 300 mg of micronized DHEA ($n = 8$). These values were measured with a direct ^{125}I radioimmunoassay; they overestimate the actual testosterone by approximately 300%.

Table II. Time-standardized mean peak serum DHEAS, DHEA, and testosterone concentrations after oral administration of micronized DHEA

	Serum steroid concentration		
	DHEAS (μg/dl)	*DHEA (ng/dl)*	*Testosterone (ng/dl)*
Placebo	83 ± 713	228 ± 54	45 ± 7
DHEA			
150 mg	1185* ± 110	1617* ± 429	183* ± 10
300 mg	1688† ± 215	2639* ± 510	311† ± 52

Amounts are mean ± SEM.

†$p < 0.05$ between peaks at 150 and 300 mg.

ilar pattern of differences is seen when the mean areas under the serum concentration-time curve for each dose preparation are compared. Dose proportionality (not shown) analysis reveals a linear plot, indicating that for this particular preparation DHEA dose proportionality exists. Analysis of the samples taken 24 hours after 150-mg dose administration in two patients revealed that the DHEAS concentrations remained approximately three times placebo levels, and the testosterone values had nearly returned to preadministration levels.

Concentrations determined in this study by the direct ^{125}I radioimmunoassays for testosterone were compared with those obtained by the tritiated assays that use preparative celite chromatography and whose specificity for these steroids was documented previously.[20] Fig. 4 compares the two methods by linear regression and demonstrates that the direct assay systematically overestimates testosterone by approximately 300%.

Liver function tests obtained after completion of each arm were within normal limits in seven of the eight subjects. In one of the participants, however, there was a rise in liver enzymes at the end of the study, with clinical hepatitis developing 2 weeks after completion. This complication was associated with preexisting antinuclear antibody titers and was resolved completely.

Comment

This study demonstrates rapid absorption and biotransformation of oral micronized DHEA to DHEAS and to testosterone proportionate to the doses given. Thus single 150 and 300 mg doses produced, respectively, supraphysiologic maximum concentrations of DHEA (1617 to 2639 ng/dl, 7 to 11.5 to fold × placebo) and DHEAS (1185 to 1688 μg/dl, 14- to 20-fold × placebo) with comparatively modest elevation of testosterone (183 to 311 ng/dl, 4- to 7-fold × placebo). When testosterone is adjusted to one third after chro-

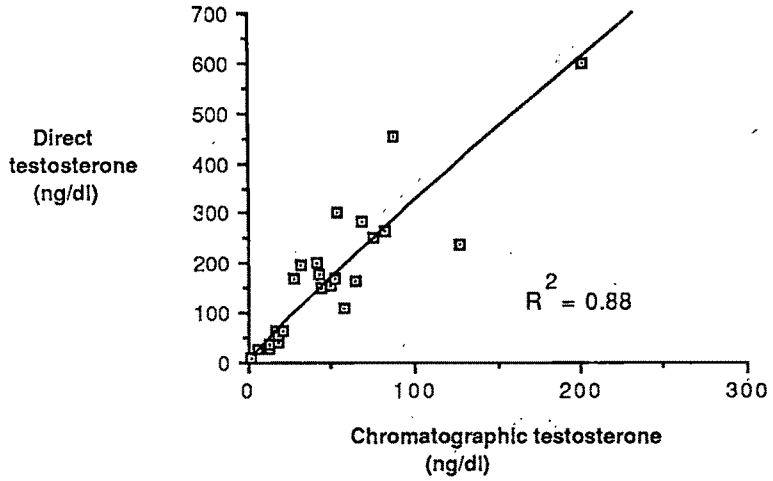

Fig. 4. Testosterone concentrations determined by direct ^{125}I radioimmunoassay versus tritiated assay with chromatography. The direct assay overestimates testosterone by 300%.

Table III. Mean areas under the serum concentration-time curve for DHEAS, testosterone, after oral administration of micronized DHEA ($n = 8$)

	Area under serum concentration-time curve		
	DHEAS (μg/min/dl)	*DHEA (ng/min/dl)*	*Testosterone (ng/min/dl)*
Placebo	42,415 ± 8,768	17,198 ± 14,063	22,753 ± 3,646
DHEA			
150 mg	540,027* ± 35,757	683,810* ± 125,124	91,193* ± 3,994
300 mg	757,493*† ± 89,509	903,735* ± 93,570	149,262*† ± 20,643

Amounts are mean ± SEM.

matographic assay, mean testosterone concentrations remain within normal premenopausal levels throughout the 12 hours after the 150 mg dose. By extrapolation from Figs. 1 through 3, 50 to 75 mg daily of this DHEA preparation may be expected to approximate the premenopausal adrenal androgen milieu. Thus the premenopausal patient would accrue benefits of premenopausal DHEA concentations without incurring deleterious effects from excess of potent androgen metabolites.

To our knowledge this is the first systematic investigation of DHEA given to postmenopausal women in replacement doses. However, DHEA administered in much higher doses (1600 mg per day) to obese postmenopausal women was associated with deleterious androgenic effects. In that study, six obese postmenopausal women treated for 28 days developed insulin resistance and decreased sex hormone–binding globulin in association with substantial increases in testosterone and dihydrotestosterone.[19] We postulated that lower doses with a strategy to bypass or overwhelm hepatic metabolism could potentially deliver a more physiologic androgen environment.

Normally, adrenal androgens are secreted into the systemic circulation. Therefore oral administration of DHEA with its consequent hepatic first-pass effect is unphysiologic. Our strategy combines micronized DHEA particles for rapid portal entry to overwhelm hepatic metabolism of the native steroid with a lipophilic vehicle designed to bypass the liver via lymphatics. Previous studies of oral DHEA administration used formulations of plain, milled, crystalline DHEA with no matrix.[17, 19, 22, 23] This form of DHEA, theoretically subject to substantial hepatic first-pass effect, produces high conversion of DHEA to biologically active androgens and concomitantly reduces the native DHEA bioavailability.[19] Our approach is based on a report by Kincl et al.[24] in which the bioavailability of native progesterone was significantly increased by administration with a cholesterol fatty acid ester.[24] Further studies in rats by the same authors revealed enhanced lymphatic absorption and transport with the fatty acid preparation, thus bypassing liver metabolism.[24, 25] Expanding on this principle we combined DHEA, micronized to <10 μm particles, with a lipid matrix. With micronization we sought to overcome some first-pass effect by

rapid portal entry of steroid. With the lipid matrix we hoped to bypass the liver via the lymphatic system.[54] By rough comparison administration of DHEA in this study produced higher DHEA and comparable DHEAS and testosterone concentrations, with one third of the dose of milled, crystalline DHEA reported elsewhere.[19] We made no direct comparisons in this preliminary study, which was designed only to examine dose effects.

In this single-dose study serum estradiol did not increase. A previous multidose study revealed both estrone and estradiol increase after 3 weeks of therapy to 40 to 50 pg/ml and 30 to 40 pg/ml, respectively.[19] Conversion of DHEA to androgens and further aromatization to estrogen may be induced with chronic DHEA therapy not evident in this single-dose study. Thus postmenopausal women given DHEA may not only benefit by the specific salutary effects of this hormone; they also may require less or no estrogen.

This preliminary study explores the possibility of a physiologic postmenopausal adrenal androgen replacement regimen. Given the numerous reported benefits of DHEA in animal and human studies, postmenopausal replacement is intuitively attractive and worthy of further investigation.

We thank Charles Hakala, RPh, of the Belmar Pharmacy, Lakewood, Colorado, for preparing the micronized DHEA tablets.

Discussion

Dr. Robert B. Jaffe, San Francisco, California (Fellow). The reasons for the existence of such high concentrations of DHEA during fetal, peripubertal, and adult life have remained enigmatic and intriguing for

many years. So, too, has the decline of DHEA and DHEAS with aging.

During intrauterine fetal life, DHEAS is quantitatively the major androgen secreted by the fetal adrenal gland. It is produced principally by the unique fetal zone of the gland[1] and, after 16-hydroxylation in the fetal liver and adrenal gland, is used after further metabolism as a substrate for placental estrogen. The production of DHEAS by the fetal adrenal gland is stimulated by corticotropin.[2] A putative adrenal androgen stimulating hormone distinct from corticotropin did not stimulate fetal DHEAS production.[3] Whether DHEA and DHEAS have other functions during intrauterine life awaits further elucidation.

After birth DHEAS increases significantly before puberty, an event known as adrenarche. This is associated with the initiation of sex hormone–dependent hair growth and is likely independent of menarche. Concentrations of DHEAS rise to peak levels during the third decade and then gradually decline. Some have referred to the diminution of DHEAS production as the adrenopause.

As indicated by the authors, several beneficial effects of DHEA administration have been suggested in the last several years. These have included inhibition of neoplasia, decrease in cardiovascular disease, and prevention of osteoporosis. However, administration of DHEA in different vehicles and for more prolonged periods has produced changes associated with the polycystic ovarian syndrome, namely increased insulin resistance, decreased sex hormone–binding globulin, and significant increases in testosterone and its 5α-reduced reduced metabolite, dihydrotestosterone.[4] Thus long-term administration of DHEA should be approached with caution.

A literature search on DHEA reveals that in addition to those effects, DHEA also has been reported to stimulate gene expression in the prostate gland,[5] stimulate growth of a prostatic carcinoma cell line,[6] inhibit the growth of fibroblasts and their differentiation into adipocytes (perhaps the reason for its purported benefits in obesity)[7] protect against acute lethal viral infections,[8] inhibit the hepatic glucose-6-phosphatase system,[9] enhance interleukin-2 synthesis by helper T cells,[10] augment oxidant injury by inhibiting rabbit lung glucose-6-phosphate dehydrogenase,[11] and demonstrate antiglucocorticoid action.[12] Therefore there are a number of both potentially beneficial and detrimental effects of this steroid, formerly believed to be largely inactive.

To obviate some of the potential deleterious effects of the steroid, the authors have developed a novel lipophilic matrix; they postulate that lipophilic vehicle will allow the DHEA to bypass the liver and enter the lymphatics.

The authors have administered single doses of micronized DHEA (150 and 300 mg) to eight postmenopausal women in a randomized fashion. They have studied the increases in DHEA, DHEAS, testosterone, and estradiol for 72 hours and compared the results with those of the same group of women receiving placebos. Significant increases in DHEA and DHEAS values over control levels were reached with both doses, with mean peak values of DHEAS seen at approximately 240 to 300 minutes and those of DHEA at approximately 100 minutes. A dose-dependent effect was noted at multiple time points for DHEAS and at the time of peak DHEA concentrations. Serum testosterone also increased significantly after the short-term oral administration of DHEA and remained elevated 720 minutes after administration. No significant change in estradiol was observed. It would have been of interest to measure estrone as well, because aromatization of androstenedione, a more proximate product of DHEA bioconversion, is primarily to estrone.

The study is relatively straightforward. The administration of oral micronized DHEA produced the expected rises in DHEA and DHEAS. Single-dose administration is an appropriate prelude to longer-term dosing.

However, several cautions and questions should be raised. First, although the vehicle is different from those previously and one that the authors postulate should not be associated with deleterious effects of DHEA administered in a nonlipophilic matrix, this remains to be determined. The increase in insulin resistance, decrease in sex hormone–binding globulin, and increase in potent circulating and locally formed androgens are concerns. Further, the authors state that postmenopausal women would "accrue benefits of premenopausal DHEA concentrations without the deleterious effects from an excess of potent androgen metabolites." Unfortunately, however, they have not measured androgen metabolites other than testosterone.

Additionally, finding elevated liver function studies and hepatitis in one of the eight women after single-dose administration is also a concern, particularly when long-term use is contemplated. This could, of course, just have been a chance event.

Because the authors found that the assay used for quantitation of testosterone in unextracted serum overestimated true testosterone values by 300%, it would have been preferable if all samples had been reassayed with an extraction procedure rather than arbitrarily reducing the levels by a third. The authors did, however, demonstrate a linear correlation between unextracted and extracted values.

Further, the authors state that pharmacologic doses of DHEA exert "salutary effects on serum lipoprotein profiles." How should this statement be interpreted in view of the known deleterious effects on liver lipoprotein information caused by chronic administration of androgenic compounds?

The authors state that there was only a "comparatively modest" rise in testosterone. However, testosterone is a much more potent androgen than DHEA or DHEAS. Therefore even a modest rise should not be ignored.

The authors have carried out a careful study with a novel lipophilic matrix for what may be a useful com-

pound. The data are clearly presented and analyzed and the possible shortcomings and some of the potentials risks noted. Obviously a good deal more work needs to be performed before the long-term efficacy and safety of this steroid can be determined.

Dr. Robert A. Wild, Oklahoma. What was the effect on hot flashes?

Dr. Buster (Closing). In response to the first question, we measured estrone, and the values were <30 pg/ml. There was no increase in the concentrations of estrone after DHEA. We did the measurements after we submitted the manuscript, and that is why you did not see it in the paper.

The second question has to do with the vehicle, the DHEA dose, and the effects it produces. The lipid matrix vehicle allows us to partially bypass the liver. We hoped it would change the profile of metabolites. Of particular concern is the conversion of oral DHEA to testosterone and its effect on insulin resistance. We hoped that with the lipid matrix the absorption by the lymphatic system would allow some bypassing of the liver. We were reassured when we did not see as much testosterone conversion as had been the case in previous studies with crystalline steroid.

The critical issue, though, was not with the vehicle but with the DHEA dose. The doses used were actually the lowest that we have seen. The end point we were seeking was a dose low enough to keep the testosterone within a physiologic range. The idea was to avoid some of the problems of high testosterone that had been seen previously.

The underlying purpose of the study was to find a dose of DHEA suitable for replacement. We looked at the testosterone level as one of several critical end points required to design the multiple-dose study that we plan to do next. In that study we will seek to avoid producing the insulin resistance effects that were seen in the previous studies.

The last issue that Dr. Jaffe mentioned was that of lipoproteins. In looking at the literature, we found that reports are at variance as to the effect of DHEA on lipoproteins. Existing studies uniformly show a decrease in cholesterol, but the ratio of high density and low density varies between the studies. The animal data are similarly confusing. We hope that with lower doses and with lipid matrix, the larger portion of DHEA that bypasses the liver will allow the liver to produce the beneficial metabolites without excess testosterone. This issue has to be looked at very carefully before beginning additional studies on a large scale.

We certainly do have more work planned with replacement DHEA. A long-term repeat dose study is being designed; its purpose is to analyze the biologic effects of DHEA replacement. We hope that with lower DHEA doses the problems with the virilizing effects of testosterone we had observed previously will not continue. At the same time we hope that things that seem to be good about DHEA can still be obtained. I imagine that like everything else there are many counterbalancing effects, both good and deleterious, that we have to look for. More work is planned.

Regarding Dr. Wild's question about hot flashes, of course the women on the study were off estrogen. One of the women who took the drug began having hot flashes as the dose cleared from her circulation. A curious observation.

Endothelium-derived relaxing factor and indomethacin-sensitive contracting factor alter arterial contractile responses to thromboxane during pregnancy

Carl P. Weiner, MD, Loren P. Thompson, PhD, Kang-Zhu Liu, MD, and James E. Herrig, BS

Iowa City, Iowa

OBJECTIVES: Pregnancy reduces uterine artery contractile responses to norepinephrine and angiotensin II in many species, including the human and the guinea pig, by release of endothelium-derivec relaxing substances. We hypothesized that vascular reactivity to thromboxane during pregnancy would also be reduced by a similar mechanism.

STUDY DESIGN: Isolated ring segments of uterine and carotid arteries from nonpregnant and near-term pregnant guinea pigs were suspended in a myograph for the measurement of isometric tension.

RESULTS: Uterine but not carotid artery sensitivity to cumulative addition of the thromboxane analog U46619 was decreased during pregnancy. The maximal contractile responses of both vessels were unaltered by pregnancy. Nω-nitro-L-arginine (10^{-4} mol/L), an inhibitor of nitric oxide endothelium-derived relaxing factor synthesis, increased the sensitivity of uterine and carotid arteries to U46619 in both pregnant and nonpregnant animals. The maximal contractile response of uterine arteries from pregnant guinea pigs was also increased, but that of nonpregnant ones was not. The maximal U46619 contractile response of the carotid artery was not significantly altered by Nω-nitro-L-arginine. Indomethacin (10^{-5} mol/L), a cyclooxygenase inhibitor, reduced both the sensitivity and the maximal response of U46619 in each vessel group. Removal of the endothelium from uterine artery of pregnant animals enhanced both sensitivity and maximal response to U46619. Pretreatment of the denuded segments with indomethacin reduced the sensitivity to U46619. However, indomethacin-treated denuded segments were still more sensitive to U46619 than controls.

CONCLUSION: The sensitivity of guinea pig uterine artery but not carotid artery to thromboxane is reduced during pregnancy. Although the precise mechanism remains unclear, both endothelium-derived relaxing factor and an indomethacin-sensitive contracting factor are involved. If indomethacin-sensitive contracting factor is released by humans and disease alters that release, it is possible that any enhanced contractile response to thromboxane resulting from the loss of endothelium-derived relaxing agents such as prostacyclin and endothelium-derived relaxing factor would be offset by the loss of indomethacin-sensitive contracting factor. (Am J Obstet Gynecol 1992;166:1171-81.)

Key words: Pregnancy, thromboxane, U46619, endothelium-derived relaxing factor, prostacyclin, Nω-nitro-L-arginine, indomethacin, uterine artery, carotid artery, guinea pig

Pregnancy profoundly alters blood flow. For example, flow through the uterine artery of the guinea pig increases 3500% above that of the nonpregnant animal.[1] Although it is clear that the redistribution of an increased cardiac output to certain organs is crucial for a successful pregnancy, the mechanisms by which this redistribution occurs are poorly understood. It is associated with decreased uterine artery contractile responses to norepinephrine and angiotensin II[2, 3] coupled with increased prostacyclin[4, 5] and nitric oxide endothelium-derived relaxing factor (EDRF).[6, 7] The latter is synthesized from L-arginine by nitric oxide synthetase. Increased prostacyclin contributes to the reduction in uterine artery sensitivity to angiotensin II,[5] whereas the decreased contractile responses of uterine artery to norepinephrine result directly from enhanced nitric oxide EDRF.[8]

Pregnancy also has a profound effect on coagulation. There is enhanced but, for the most part, balanced consumption of both soluble clotting and platelet components.[9] This balance is lost in women with preeclampsia and in women whose fetuses are growth restricted

because of uteroplacental insufficiency. In each the endothelium appears dysfunctional[10-14] and both the thromboxane/prostacyclin ratio and the consumption of is platelets increased.[15-19] Several investigators have hypothesized that the platelet-released thromboxane in these disorders is the cause of the increased systemic or placental resistance or blood pressure.[17-19] In support of this hypothesis, aspirin at a dose that reduces both platelet aggregability and circulating thromboxane but does not significantly affect endothelial prostacyclin synthesis[20] decreases the incidence of preeclampsia[21] and improves fetal growth in pregnancies complicated by uteroplacental dysfunction.[22] Thus it is important to understand the effect of pregnancy on vascular responses to thromboxane.

A few studies have examined the effect of thromboxane on the uterine circulation. Uterine ischemia in the dog causes hypertension as a result of thromboxane released by the uterine vascular bed.[23] The infusion of a stable thromboxane analog, U46619, constricts the ovine fetal-placental vasculature. The constriction is not reversed by prostacyclin.[24] Neither the effect of pregnancy on contractile responses to U46619 nor the endothelium-derived factors that might modulate it have been investigated. We hypothesized that, like norepinephrine and angiotensin II, the contractile response of vascular smooth muscle to U46619 would be decreased during normal pregnancy and that EDRF or prostacyclin would play a role in that reduction. Because both release and action of these potential modulators are local, we tested this hypothesis with isolated uterine and carotid arteries from pregnant and nonpregnant guinea pigs.

Material and methods

The protocols used for this investigation were approved by the University of Iowa Animal Care Committee.

Preparation: Suspended arterial rings. Adult female nonpregnant and pregnant (50 to 60 days' gestation, term 65 to 68 days) mixed breed guinea pigs were anesthetized (ketamine hydrochloride 80 mg/kg intraperitoneally, xylazine 3 mg/kg intramuscularly). The common carotid and main uterine arteries were removed en bloc with microsurgical techniques as described previously.[2, 7] The uterine artery was selected because of its dramatic increase in blood flow during pregnancy[1] and our prior demonstration of decreased norepinephrine contractile responses with enhanced EDRF.[8] The carotid artery was selected because contractile responses to norepinephrine were unaffected by pregnancy.[8] The vessels were placed into iced Krebs-Ringer solution composed of sodium chloride 118 mmol/L, calcium chloride 2.2 mmol/L, potassium chloride 4.7 mmol/L, $MgSO_4 7HOH$ 1.2 mmol/L, potassium orthophosphate 1.21 mmol/L, sodium bicarbonate 25 mmol/L, and glucose 11.1 mmol/L. They were cleaned of loose connective tissue, cut into 3 mm rings free of side branches, and suspended on two 50 μ tungsten wire triangles. One triangle was hooked to a stationary rod and the other to a strain gauge transducer (Grass FT 0.03, Quincy, Mass.) for the measurement of isometric force. The rings were suspended in 25 ml chambers filled with Krebs-Ringer solution maintained at 37° C and aerated with 95% oxygen and 5% carbon dioxide. The pH of the baths was maintained between 7.38 and 7.45.

After 60 minutes, the rings were stretched incrementally to their individual optimal resting tensions. Optimal resting tension was determined by the contractile responses to 40 mmol/L potassium chloride. Subsequently, the rings were constricted (with either prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$) (5×10^{-6} mol/L) or phenylephrine (10^{-4} mol/L)) to 70% to 80% of maximal response and challenged with acetylcholine (10^{-4} mol/L). Relaxation confirmed the presence of functionally intact endothelium.[7] Rings unresponsive to acetylcholine were discarded.

At the conclusion of an experiment, the ring was opened longitudinally, and the circumference (millimeters) and weight (milligrams) were recorded after the vessel was first lightly blotted dry with a paper towel. The cross-sectional area (square millimeters) was calculated by:

$$\text{Area} = 2 \times (\text{Wet weight}/1.06) \times \text{Circumference}$$

where 1.06 represents an estimate of tissue density (milligrams per cubic millimeter). Isometric force was normalized for the cross-sectional area of each tissue segment.[25]

Experiments. To determine whether pregnancy alters vascular responsiveness to the cumulative addition of U46619 (10^{-10} to 10^{-5} mol/L), the contractile responses were measured in suspended uterine and carotid arteries from pregnant and nonpregnant guinea pigs.

To determine whether EDRF modulates the vascular response to U46619, contractile responses were measured in suspended uterine and carotid arteries pretreated with a potent inhibitor of nitric oxide EDRF synthesis—Nω-nitro-L-arginine (10^{-4} mol/L for 30 minutes before the experiment).[26]

To determine whether cyclooxygenase products modulate the contractile response to U46619, contractile responses were measured in suspended uterine and carotid rings pretreated with indomethacin (10^{-5} mol/L for 30 minutes before and during the experiment).

To determine whether the endothelium was the site of the pregnancy-associated changes, uterine artery

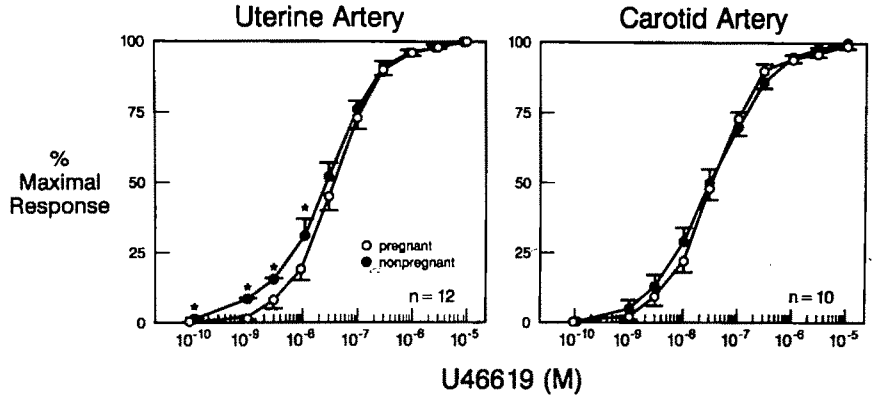

Fig. 1. Effect of pregnancy on uterine *(left panel)* and carotid *(right panel)* arteries sensitivity to cumulative doses of thromboxane analog U46619. Pregnant *(open circle)*, $n = 12$; nonpregnant *(closed circle)*, $n = 10$. There is a significant decrease in sensitivity of uterine artery from pregnant animals to U46619. Carotid artery sensitivity was unaltered by pregnancy. *Asterisk*, Significant difference at that dose by unpaired t test ($p < 0.05$). *M*, mol/L.

segments from pregnant animals were mechanically denuded by passing a 4-0 silk suture through the lumen. Destruction of the endothelium was confirmed by the loss of acetylcholine-stimulated relaxation. Subsequently, cumulative responses to U46619 were measured in the absence and presence of indomethacin.

Control segments for each experiment were run in parallel. All experiments were performed in the presence of desipramine (10^{-5} mol/L), hydrocortisone (10^{-5} mol/L), and propranolol (10^{-5} mol/L) to block neuronal and extraneuronal uptake of norepinephrine and β-adrenergic receptors, respectively.[27, 28]

Drugs. The following drugs were used: acetylcholine hydrochloride, desipramine, hydrocortisone, indomethacin, propranolol, U46619, and Nω-nitro-L-arginine (Sigma Chemical Co., St. Louis), $PGF_{2\alpha}$ (Upjohn Pharmaceuticals, Kalamazoo, Mich.), ketamine hydrochloride (Bristol Meyers Co., Syracuse, N.Y.), and xylazine (Miles Laboratories, Shawnee, Kan.). All drugs and buffers were prepared immediately before the experiment and stored on ice until used. Concentrations are expressed as the final molar concentration in the vessel chamber.

Analyses. The data are expressed either as the mean ± SEM or as the percent of the maximal response to the agonist U46619 in the experiment; n refers to the number of animals. Inhibition of acetylcholine-stimulated relaxation by Nω-nitro-L-arginine and its effect on $PGF_{2\alpha}$-induced tone were tested with paired and unpaired t tests. Dose-response analyses used a two- or three-way random block repeated-measures analysis of variance. Either contractile force and the percent maximal response were the dependent variables and dose, pregnancy status, and treatment the independent variables (blocking by animal). If the mean values for the analysis of variance were found to be significantly different ($p \leq 0.05$), either a Scheffé or t test was applied. Thus, in spite of large standard errors caused by interanimal variability, statistically significant differences among independent variables could be discerned.

Results

Effect of pregnancy on contractile responses to U46619. Significant dose-dependent contractile responses to U46619 were documented in each experimental sequence. The sensitivity to U46619 was significantly reduced in uterine (but not carotid) arteries from pregnant animals compared with nonpregnant ones (Fig. 1). Pregnancy had no effect on the maximal response of uterine and carotid arteries to U46619 (not shown).

The maximal contractile response for each ring to potassium chloride (120 mmol/L) was determined at the conclusion of some experiments. Pregnancy enhanced potassium chloride–induced contractions of uterine arteries (676 ± 87 vs 348 ± 99 mg/mm², $p = 0.01$, $n = 16$), whereas the response of the carotid artery was not unaltered (2502 ± 361 vs 2127 ± 222 mg/mm², $p = 0.21$, $n = 16$). Thus the effect of pregnancy on smooth muscle contractile responses varied with the agonist. If the contractile responses were normalized to the 120 mmol/L potassium chloride response, the maximal contractile response of uterine arteries to U46619 would be reduced during pregnancy. Acetylcholine-stimulated relaxation of preconstricted control uterine artery segments was increased by pregnancy (56% ± 6% vs 29% ± 3%, $p = 0.0006$).

Effect of EDRF inhibition on U46619 contractile responses. Nω-nitro-L-arginine reduced acetylcholine-stimulated relaxation of preconstricted uterine and carotid arteries regardless of pregnancy status (Table I).

Table I. Effect of Nω-nitro-L-arginine on $PGF_{2\alpha}$-stimulated arterial contraction and acetylcholine-stimulated relaxation (n = 8)

	Uterine artery		*Carotid artery*	
	Pregnant	*Nonpregnant*	*Pregnant*	*Nonpregnant*
Acetylcholine (percent relaxation)				
Control	48 ± 10	24 ± 2*	84 ± 4	88 ± 4
Nω-nitro-L-arginine	24 ± 9*	5 ± 2†	40 ± 4†	37 ± 7†
$PGF_{2\alpha}$ (mg/mm²)				
Control	821 ± 151	840 ± 175	501 ± 54	360 ± 75
N-ω-nitro-L-arginine	1116 ± 146†	1100 ± 274†	751 ± 66†	527 ± 101†

Values are mean ± SEM.
*$p < 0.05$, from pregnant.
†$p < 0.05$, from control.

Nω-nitro-L-arginine enhanced $PGF_{2\alpha}$ tone in the uterine and carotid arteries (Table I). The mean percent increase in the contractile response of uterine artery to 5×10^{-6} mol/L $PGF_{2\alpha}$ from pregnant animals compared with nonpregnant animals did not reach significance in this series (44% ± 11% vs 27% ± 12%, respectively, p = not significant). The maximal contractile response to 120 mmol/L potassium chloride was unaltered by Nω-nitro-L-arginine in either vessel (not shown).

Nω-nitro-L-arginine enhanced the maximal contractile response to U46619 of uterine arteries obtained from pregnant animals compared with nonpregnant ones (1590 ± 161 vs 1879 ± 111 mg/mm², $p < 0.05$) (Fig. 2). The contractile response of uterine artery from nonpregnant animals to U46619 was not significantly altered by Nω-nitro-L-arginine. The effect of Nω-nitro-L-arginine appeared greatest at the upper end of the U46619 dose-response curve. Nω-nitro-L-arginine also enhanced the sensitivity of uterine and carotid arteries from pregnant animals and carotid artery from nonpregnant animals to U46619 compared with untreated controls (not shown). Thus nitric oxide EDRF blockade had the least effect on the vessel with the smallest baseline relaxation response to acetylcholine—uterine artery from nonpregnant animals.

Effect of indomethacin on U46619 contractile responses. Neither the acetylcholine-induced relaxation nor the phenylephrine-induced contraction from which that relaxation was measured was altered by indomethacin.

The effect of indomethacin on contractile responses to U46619 was not pregnancy dependent. Indomethacin reduced the sensitivity of both uterine and carotid arteries to U46619 (Fig. 3). The effect of indomethacin on the dose-response curve was most noticeable on the lower end. Because the reduction in uterine artery sensitivity during pregnancy to U46619 also occurred at the lower end of the dose-response curve, contractile responses of uterine artery to U46619 no longer differed between pregnant and nonpregnant animals after indomethacin (not shown). Perhaps because of the wide interanimal variation in contractile responses to high concentrations of U46619, the maximal contractile response to U46619 was significantly reduced by indomethacin only in the carotid arteries obtained from pregnant animals (Fig. 4).

Effect of endothelial destruction on U46619 contractile responses. Removal of the endothelium from uterine arteries of pregnant animals abolished the acetylcholine-induced relaxation and enhanced their sensitivity to U46619 (Fig. 5). Treatment of the denuded vessels with indomethacin reduced their sensitivity to U46619. However, the sensitivity of indomethacin-treated denuded vessels was still greater than control. The rise in the maximal contractile response to U46619 after denudation did not reach significance (1321 ± 95 versus 1766 ± 220 mg/mm², p = not significant).

Comment

In the nonpregnant animal and human, platelet aggregation and the response of vascular smooth muscle to contractile agents are modulated by the release of endothelium-derived substances such as nitric oxide EDRF and prostacyclin.[29] During the human and guinea pig pregnancy, acetylcholine-stimulated nitric oxide EDRF relaxation of the uterine artery is increased.[6, 7] Sheep uterine artery synthesis of prostacyclin during pregnancy is also increased.[4] Recently we demonstrated that the decreased contractile responses of uterine artery to norepinephrine that are characteristic of pregnancy result directly from enhanced nitric oxide EDRF release.[8] Previously, Magness[5] observed that the decreased sensitivity of uterine artery to angiotensin II during pregnancy is secondary to enhanced release of endothelium-derived prostacyclin. These findings lead us to postulate that the enhanced release of endothelium-derived dilator substances during pregnancy would also reduce the contractile responses of uterine artery to thromboxane. If any re-

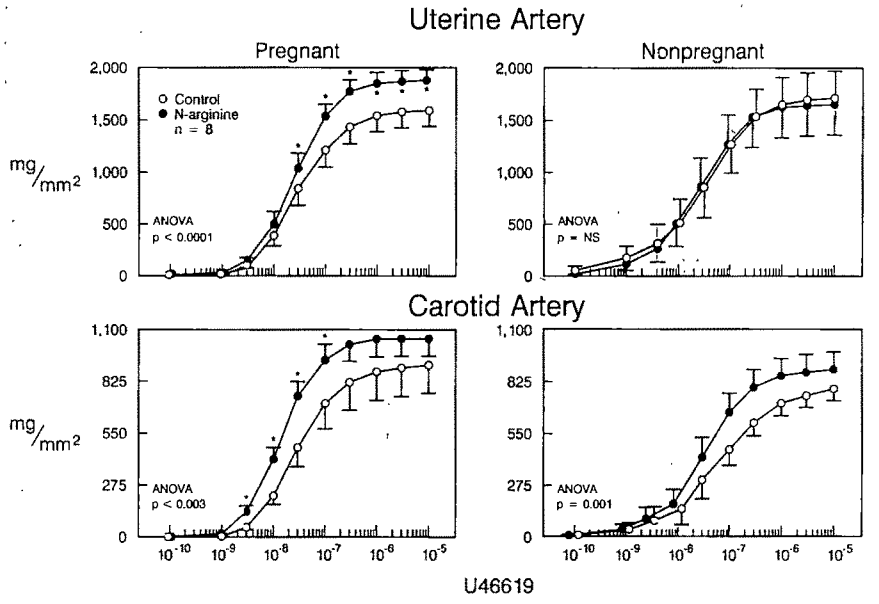

Fig. 2. Effect of Nω-nitro-L-arginine *(N-arginine)* on cumulative contractile responses of uterine *(upper two panels)* and carotid arteries *(lower two panels)* to U46619. Pregnant *(left panels)*, $n = 8$; nonpregnant *(right panels)*, $n = 8$. Maximum contractile response of uterine artery obtained from pregnant animals was enhanced significantly compared with control *(open circles)*. *Asterisk*, Significant difference at that dose by paired t test ($p < 0.05$). Analysis of variance *(ANOVA)* refers to comparison of two curves.

duction in sensitivity to thromboxane was dependent on enhanced tonic or stimulated release of these endothelium-derived dilators, then a pregnancy disorder characterized by increased release of platelet-derived thromboxane could result in vasospasm. Because these endothelium-derived modulators are locally acting substances, we examined then in vitro to eliminate the uncontrollable variables inherent to the in vivo study of contractile agents.

We found that the sensitivity of uterine but not carotid artery to U46619 was reduced during pregnancy. Pregnancy increased the maximum potassium chloride–induced contractile response by a mechanism currently under investigation. When the responses to U46619 were normalized to the potassium chloride maximum, there was a right shift of the dose-response curve during pregnancy. This suggests that either thromboxane receptor number or affinity is reduced during pregnancy or that modulators of the smooth muscle response to thromboxane are altered. Although not examined in this study, gender-dependent differences in prostaglandin receptors have been reported.[30]

To determine the role of nitric oxide EDRF in modulating the contractile response to thromboxane during pregnancy, we inhibited its synthesis from L-arginine by nitric oxide synthetase[31] with Nω-nitro-L-arginine.[26] Stimulated release of nitric oxide EDRF by acetylcholine as evidenced by increased relaxation was significantly greater in uterine artery from pregnant animals than from nonpregnant ones. Nω-nitro-L-arginine enhanced the response of uterine and carotid arteries to $PGF_{2\alpha}$ and inhibited acetylcholine-stimulated nitric oxide EDRF relaxation in both uterine and carotid arteries. In prior studies we found that the contractile response to $PGF_{2\alpha}$ was enhanced significantly more in uterine arteries from pregnant animals than from nonpregnant ones.[18] The current study supports that observation. This suggests that tonic release of nitric oxide EDRF from uterine artery is also increased during pregnancy. Nitric oxide EDRF blockade by Nω-nitro-L-arginine enhanced the sensitivity of uterine and carotid arteries to U46619 regardless of pregnancy status. Nitric oxide EDRF blockade did not affect U46619 contractile responses of uterine arteries from nonpregnant animals. This suggests that the modulation of U46619 contractile responses in the uterine artery by either tonic or stimulated release of nitric oxide EDRF is specific for pregnancy. The findings also suggest that nitric oxide EDRF modulates the U46619 contractile response of carotid artery regardless of pregnancy status.

To determine the potential effect of cyclooxygenase products on contractile responses to U46619, we inhibited the pathway with indomethacin. We selected indomethacin because it increases the systemic pressor response of pregnant humans and a variety of animals to angiotensin II.[32, 33] We found that indomethacin also alters the contractile responses of both uterine and carotid artery to U46619 but decreased rather than in-

Pregnant *(left panels)*, $n = 6$; nonpregnant *(right panels)*, $n = 6$. Sensitivity was significantly diminished by indomethacin *(closed circles)* in each vessel group compared with control *(open circles)*. *Asterisk*, Significant difference at that dose by paired t test ($p < 0.05$).

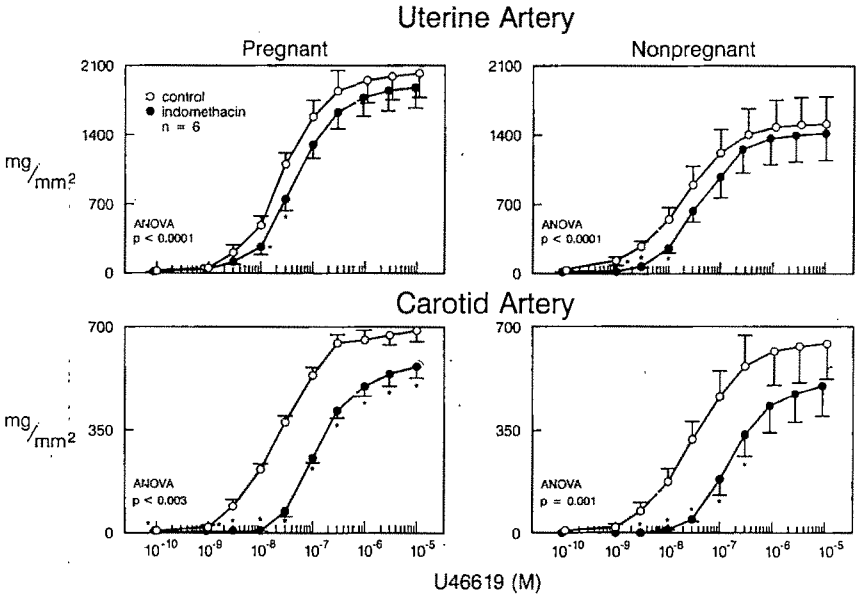

Fig. 4. Effect of indomethacin on contractile responses to cumulative doses of U46619 in uterine artery *(upper panels)* and carotid artery *(lower panels)* from nonpregnant *(left panels)* and pregnant *(right panels)*. Indomethacin *(closed circles)* caused significant right shift in contractile responses to U46619 compared with control *(open circles)*. *Asterisk*, Significant difference at that dose by paired t test ($p < 0.05$). Analysis of variance *(ANOVA)* refers to comparison of two curves.

creased sensitivity as had been expected. Indomethacin affected uterine and carotid artery contractile responses to U46619 regardless of pregnancy status. The percent decrease in contractility after indomethacin was much greater in the carotid artery than in the uterine artery. This suggests that U46619 stimulates the release of an indomethacin-sensitive contracting factor from both uterine and carotid arteries. However, indomethacin-sensitive contracting factor has a greater role in modulating carotid artery response to U46619 as compared with uterine artery response.

Although both nitric oxide EDRF blockade and in-

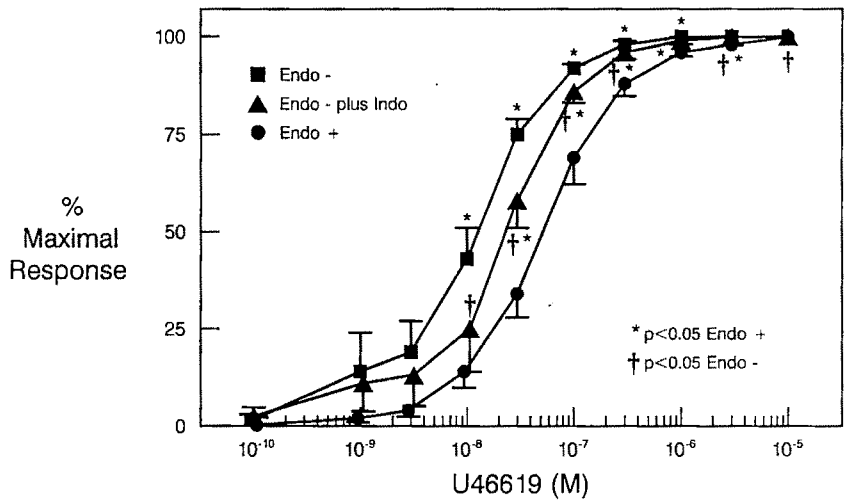

Fig. 5. Effect of mechanical removal of endothelium in uterine artery from pregnant animals, $n = 7$. Denudation *(closed square)* enhanced contractile responses to U46619 compared with control *(closed circle)*. Addition of indomethacin to denuded segments *(closed triangles)* decreased sensitivity to U46619 compared with that of denuded segments. However, contractile responses were still greater than control. *Asterisk*, $p < 0.05$, compared with endothelium-intact control; *dagger*, $p < 0.05$, compared with endothelium-denuded segments.

domethacin altered the U46619 dose-response curve, their principal impact was on different portions of the curve. The effect of nitric oxide EDRF blockade was greatest on the upper portion of the dose-response curve, whereas the effect of indomethacin was greatest on the lower portion. This suggests that more than one mechanism modulates the uterine artery response to thromboxane. Because (1) the effect of indomethacin was on the same portion of the curve altered by pregnancy and (2) the responses of uterine arteries from pregnant and nonpregnant animals were similar after indomethacin, we would speculate that pregnancy decreases an indomethacin-sensitive contracting factor, which could account for reduced vascular reactivity to U46619.

Removal of the endothelium from uterine arteries of pregnant animals enhanced the sensitivity to U46619. This confirms that EDRF release by the uterine artery modulates the contractile response to U46619. The addition of indomethacin to denuded rings reduced the sensitivity to U46619, although they remained significantly more sensitive to U46619 than did the control rings. This demonstrates that at least some of the indomethacin-sensitive contracting factor released by the uterine artery is produced by the smooth muscle.

Although this is the first investigation into the effect of pregnancy on contractile responses to thromboxane and the factors that might modulate it, the responses of pulmonary artery to U46619 have been studied in male and nonpregnant female guinea pigs.[34] The response of the pulmonary artery was different from that observed for the uterine artery. Removal of the pulmonary artery endothelium reduced the maximal contractile response to U46619 only in vessels obtained from female animals and not in those obtained from male animals. We have previously found that the contractile responses of carotid arteries to U46619 from female guinea pigs were reduced by indomethacin, but the responses of those vessels from the male were unaltered (Weiner CP, et al. Unpublished observations). These findings suggest that the site of synthesis and release of indomethacin-sensitive contracting factor can vary among vascular beds and that it is a characteristic of the female vasculature.

Preeclampsia and some types of idiopathic growth retardation are associated with a reduction in prostacyclin synthesis.[14, 17-19] Coupled with other markers of endothelial health, both of these disorders are also associated with dysfunctional endothelium,[10-18] culminating in an altered prostacyclin/thromboxane ratio and enhanced platelet consumption.[35] We would speculate that nitric oxide EDRF synthesis or release, like prostacyclin, is also reduced in pregnancies complicated by these disorders. If the response of the human is similar to that of the guinea pig, as it is for the effect of pregnancy on norepinephrine/angiotensin II–stimulated constriction and acetylcholine-stimulated nitric oxide EDRF relaxation, any reduction in endothelium-derived relaxing substances might be offset by a concurrent reduction in indomethacin-sensitive contracting factor. As a result, smooth muscle response to thromboxane could remain the same or decrease rather than increase as has been suggested.[17-19]

In conclusion, the contractile responses of uterine

but not carotid artery to thromboxane are reduced during pregnancy. The effect of EDRF blockade on uterine contractile responses to thromboxane are specific for pregnancy. Thromboxane stimulates the release of an indomethacin-sensitive contracting factor from both uterine and carotid arteries. The contracting factor plays a greater role in modulating the carotid artery responses to thromboxane than it does in the uterine artery. Each endothelial factor is important, but neither alone definitively accounts for the effect of pregnancy on uterine artery sensitivity to thromboxane. If this contracting factor is also released by women, it is possible that the loss or reduction of the endothelium-derived relaxing substances would be offset by the loss of contracting factor and the vascular response to thromboxane would remain unchanged.

Discussion

Dr. Valerie M. Parisi, Houston, Texas. The maternal physiologic adaptation to normal pregnancy is characterized by marked alterations in uterine perfusion and systemic vascular function. As shown in this schematic representation, the resultant relaxant effect on arteriolar tone is achieved through a complex and, as yet, an incompletely understood interaction of many vasoactive substances.

It is thought that increased endothelial production of vasodilators such as prostacyclin and EDRF during pregnancy is primarily responsible for the observed loss of vascular responsiveness to otherwise potent vasoconstrictors, such as norepinephrine and angiotensin II.

Pregnancies complicated by preeclampsia present a vascular physiologic disorder marked by an imbalance in eicosanoid production that favors vasoconstriction. Compared with control placentas, placentas from women with preeclampsia show a marked decrease in prostacyclin production coupled with increased thromboxane production.[1] Biochemical alterations in both trophoblast and placental vascular endothelium contribute to this imbalance.

Recently, investigation in this arena has focused on events occurring at the cellular and subcellular levels to further elucidate mechanisms of vascular control.

Dr. Weiner and his colleagues have elegantly studied the contractile responses of uterine and carotid arteries to the thromboxane analog U46619 during pregnancy and evaluated the role of the vasodilators prostacyclin and EDRF in these responses.

Dr. Weiner's article presents new and exciting information, as neither the effect of pregnancy on vascular responses to thromboxane nor the potential mechanisms by which it occurs have been previously studied. Their work also has enormous clinical relevance, as elucidation of mechanisms by which thromboxane acts, and subsequently may be inhibited in the pregnant vasculature, is of the utmost importance if we are to be successful in the prevention or, if necessary, the treatment of preeclampsia and other placental vascular disorders.

Dr. Weiner hypothesized that the contractile responses of vascular smooth muscle to thromboxane analog would be decreased during pregnancy. This was true for uterine but not carotid arteries. In view of the enhanced response to potassium chloride–induced contractions and the increased acetylcholine-stimulated relaxation of preconstricted uterine artery segments, is it possible that increases in uterine vascular surface area during pregnancy play a role by quantitatively increasing vasodilator production?

The authors report that EDRF inhibition by Nω-nitro-L-arginine modulated pregnant uterine artery responses to thromboxane, although curiously the effect was greatest at the upper end of the dose-response curve. Does the potential quantitative increase in thromboxane production in human disease states approach the concentrations used at this end of the curve?

Indomethacin was used to block the cyclooxygenase pathway leading to prostacyclin production and, contrary to their hypothesis, decreased the sensitivity of both uterine and carotid arteries to thromboxane analog. Unlike the effect of EDRF inhibition, indomethacin's effect was most pronounced at the lower end of the dose-response curve. Dr. Weiner attributes these observations to the presence of an indomethacin-sensitive contracting factor that is decreased in pregnancy. An alternative explanation exists. Indomethacin has produced varied and inconsistent changes in uterine perfusion in whole-animal models. Unfortunately, it is not a specific cyclooxygenase blocker but alters the lipooxygenase pathway as well and has been postulated to have intrinsic vasoactive properties.

I would like to ask Dr. Weiner if he has confirmed his observations by using another, more specific cyclooxygenase blocker and if he could speculate on the identity of the indomethacin-sensitive contracting factor.

The final segment of this article reports increased sensitivity of pregnant uterine arteries to thromboxane analog after endothelial ablation, which is then reduced by the addition of indomethacin. These observations indicate a role for uterine artery smooth muscle in the production of vasoactive substances. Others have quantitated uterine artery prostacyclin production and reported 64% derived from endothelium and 36% from vascular smooth muscle.[2] I would like to ask Dr. Weiner if his data support these percentages?

Last, although it is recognized that the majority of the vasoactive substances described in this article act by autocrine and paracrine mechanisms at the local level, we must not lose sight of the necessity for investigation in the in vivo setting. How might increased thromboxane production in human disease states have an impact on the systemic vasculature, and would there be different organ vascular responses to its increased production?

Dr. James M. Roberts, San Francisco, California. I have two questions. Would you remind us of the findings with other contractile agonists in terms of the role of indomethacin-sensitive contractile agents and EDRF from the work you've done previously?

Second, I think there is an accumulated literature that indicates that EDRF has its greatest effect on precontracted vessels. So it may well be that the results you're seeing aren't necessarily related to the dose of thromboxane but rather to the contractile state of the vessel. I wonder if you have run experiments that would allow you to sort out whether it's just that the high dose of thromboxane and the vessels were contracted or

whether it really is an independent dose-related phenomenon.

Dr. Thomas H. Kirschbaum, Bronx, New York. I wonder if you would comment in general on the relationship between the study of vasoactive agents in uterine artery versus the arteriolar bed further downstream, where changes in vascular resistance actually influence flow. My understanding is that, with respect to some vasoactive agents, differences in response have been reported between these two sites.

Dr. Raul Artal, Los Angeles, California. I would like to ask if you examined other biomechanical parameters to separate acute from chronic effects and elastic from ductile properties, such as the modulus of elasticity strain to rupture, work to rupture, and sample thickness before and after each experiment.

Dr. Weiner (Closing). First, I thank Dr. Parisi for her summary and for stressing the complexity of these interactions. It's clear that there are going to be no silver bullets, no single agent that is responsible for the diseases and the end effects of the diseases we are concerned with.

Dr. Parisi asked about the role of the increased diameter and actual weight of the uterine artery during pregnancy. In the guinea pig it increases almost threefold, and in the prior investigation that we reported in the American Journal of Obstetrics and Gynecology, we tried to quantitate whether there was any change in the number of endothelial cells present in the vessel that would account for the increased EDRF-mediated relaxation.

We found that the number of cells per unit area was unchanged, but because the unit area was increased, the total number of cells had to be increased. Could that in part be responsible for the increase in EDRF-mediated responses we see? Yes, it certainly could be. We also know that after estrogen administration the increased responsiveness to acetylcholine or the increase in EDRF occurs within hours, and I wouldn't be surprised if we hear very shortly that EDRF plays a crucial role in the estrogen-mediated increase in uterine blood flow.

Dr. Parisi also asked about the physiologic concentration of thromboxane. At the site of the platelet plug, 10^{-6} or 10^{-7} mol/L is readily achievable. Whether you would see 10^{-4} mol/L or as high as we went here, 10^{-5} mol/L, is not very likely.

However, if you look closely at the dose-response curves, you'll note that, from the standpoint of the indomethacin-sensitive contracting factor and also the nitric oxide related components, there were significant changes seen at 10^{-7} and 10^{-6} mol/L.

Dr. Parisi points out that indomethacin, although a very popular drug in obstetric investigations, is certainly not a very "clean" drug. We used indomethacin initially for this study because of its long track record and because of its documented association with an increase in angiotensin II responsiveness. We've since repeated these studies to a much smaller extent with ibuprofen and found the same responses.

When we identified this decrease in responsiveness to U46619 after pretreatment with indomethacin, we were very puzzled and went back to the literature. We came across a very exciting article in the *American Journal of Physiology,* I believe from 1983. What these investigators did was examine pulmonary arteries from male and female guinea pigs, and they found that, when they removed the endothelium, the response to U46619 increased in the male, and decreased in the female animals.

We have repeated these studies with coronary and carotid arteries from male and female animals and can confirm the finding of these investigators that this indomethacin-sensitive contracting factor is gender specific. It is not in male animals. It does appear to vary, whether it comes from the endothelium or from the smooth muscle by the vascular bed.

We have not specifically identified the contracting factor, although there is good reason to suspect, from some preliminary data and from studies done in alloxan-treated rabbits, that the factor is thromboxane and that the endothelium can, under the appropriate circumstances, synthesize thromboxane into a great concentration. We have not tried to quantitate the factor yet, and that is on our list of things to do in the future.

The final question that Dr. Parisi asked was about the variations of endothelium-derived factors, whether they be EDRF or prostacyclin or endothelium-derived hyperpolarizing factor or any of the agents that are coming to light. Clearly there is a difference among vascular beds—among vascular beds, among the arteries and veins, among hormonally sensitive vascular beds and non–hormonally sensitive beds. It makes a very exciting area of research, to explore not only the effects of pregnancy but also differences in gender by trying to quantify these differences. It holds out the possibility of gender-specific therapies.

Dr. Roberts asked about other contractile agents we and others have explored in looking at the effects in these endothelium-derived relaxing substances on contractile responses in pregnant and nonpregnant animals, and again it demonstrates that there is no silver bullet. The work from the Dallas group very clearly demonstrates, at least in the ewe, that the decreased response to angiotensin II is mediated by prostacyclin and most of that prostacyclin comes from the endothelium.

In contrast, the decreased response to norepinephrine in the guinea pig was solely the result of EDRF. In contrast, work that we presented initially at last year's Society for Gynecologic Investigation meeting, serotonin responses are decreased during pregnancy but appear not to result from either EDRF or prostacyclin. We are exploring that further in our laboratory at this time. Now with thromboxane we see a completely different fourth mechanism.

The second question, if I understood it correctly, that Dr. Roberts had was with whether the stimulated release of EDRF in response to U46619 was a dose-response phenomenon.

Certainly it's harder in the uterine artery because the

standard errors are much larger. In the larger arteries such as the carotid, EDRF inhibition substances produce almost a parallel shift. So I think this response occurs at almost all doses. We've also done some preliminary work looking at the interaction between thromboxane and serotonin in vessels with functional endothelium and nonfunctional endothelium, and as part of that we find that we have to have some active tone in the vessel. The degree of active tone appears to be less important in the interaction so long as there is some active tone there. This leads very nicely into Dr. Kirschbaum's question on the appropriateness of studying conduit vessels. Although the uterine artery in the guinea pig is small, it's still a conduit vessel.

I think in the past people have concluded that the conduit vessels were simply that. They were there to carry the blood to the resistance vessels. We now have some excellent studies suggesting that's not true, and I would direct your attention to a fascinating study that was in the *Journal of Clinical Investigation* about 4 months ago. What these investigators did in vivo was take a rat, open it up, cannulate the renal artery proximally and distally to its entry into the renal bed, and then, with a variety of techniques, either selectively inhibit EDRF or destroy the endothelium; they documented beautifully that the renal artery played a major role in regulating renal blood flow.

I do not know yet that that occurs in the uterine artery. Certainly it is a possibility. It's also quite clear that the uterine artery is responsive to changes in the hormonal milieu; I think it's reasonable at this time to postulate that some of those changes will also occur downstream.

The final question had to do with changes in the uterine artery structure other than those that occurred in response to changes in the endothelium. Clearly that occurs. We have not specifically looked at elasticity, though Griendling et al. looked at the carotid artery in the ewe several years ago and found that there was a very clear difference in the elasticity-to-collagen ratio, but they also found changes in vessel function that they could not attribute simply to changes in elasticity.

If we look at how rapidly, for example, the response to acetylcholine changes in an animal treated with estrogen, just 2 hours, it's long before there's any time for remodeling of vascular smooth muscle. Clearly there is a complex interaction of a number of factors.

Make researching easier with the Ten-Year Cumulative Index (1978-1987) to the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY

The Ten-Year Cumulative Index is a complete guide to more than 30,000 pages of original articles, case reports, letters, and editorials published in the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY from 1978 through 1987 (volumes 130 to 157). Numbering more than 800 pages, the Cumulative Index includes both a subject and an author index. This hard-cover volume is $64.50 ($69.00 international). Prices include shipping. *Payment must accompany all orders and must be in U.S. funds, drawn on a U.S. bank.*

Lp(a) lipoprotein: Relationship to cardiovascular disease risk factors, exercise, and estrogen

Rogerio A. Lobo, MD,[a] Morris Notelovitz, MD, PhD,[c] Leslie Bernstein, PhD,[b] Farouk Y. Khan, MD,[c] Ronald K. Ross, MD,[b] and Wellington L. Paul, PhD

Los Angeles, California, and Gainesville, Florida

OBJECTIVE: Lp(a) lipoprotein is a distinct lipoprotein particle that recently has been found to be associated with cardiovascular disease. A study was conducted to assess the influence of cardiovascular disease risk factors on levels of Lp(a) and to evaluate the effects of age, exercise, and estrogen on these levels.

STUDY DESIGN: Two studies, a cross-sectional study of older men (n = 105) and women (n = 75) (mean age 76 years) and a prospective study of younger postmenopausal women (mean age 48 years), were carried out. Lp(a) and other lipoproteins were measured in the two studies and differences were sought by statistical analysis.

RESULTS: In the cross-sectional study, serum Lp(a) was similar in men and women and was not influenced by age. Lp(a) levels in men and women were higher when there was more than one cardiovascular disease risk factor present ($p < 0.028$). We could not demonstrate such a relationship with other lipid and lipoprotein measurements. In the prospective study exercise alone had no influence on Lp(a) levels. Oral estrogen decreased Lp(a) levels marginally ($p = 0.08$). The decrease in Lp(a) with oral estrogen was associated with increases in triglycerides ($p < 0.01$) and very-low-density lipoprotein ($p < 0.06$).

CONCLUSIONS: These data confirm that elevated Lp(a) levels are an independent risk factor for cardiovascular disease. Lp(a) levels are primarily influenced by genetic factors and it appears estrogen may have a minor influence on its hepatic synthesis. (Am J Obstet Gynecol 1992;166:1182-90.)

Key words: Lp(a) lipoprotein, cardiovascular disease, estrogen, age, exercise

Nearly 30 years ago a genetic variation of low-density lipoprotein (LDL) that was characterized by an additional protein [apo(a)] on the LDL particle was detected.[1] This altered LDL particle, called Lp(a), is now recognized as a unique, distinct, circulating lipoprotein[2] that contributes to the heterogeneity of LDL. Lp(a) is larger than LDL, has a higher buoyant density, contains its characteristic apolipoprotein (apo B-100), and binds to the LDL receptor.[3] Lp(a) can be dissociated into separate particles of LDL and apo(a) under experimental conditions and in vivo.[3] Apo(a), which is under genetic control, is highly glycosylated and may vary considerably between individuals (200 to 700 kd), thus leading to a large range of values of Lp(a).[4]

Clinical interest in Lp(a) increased when it was realized that elevated levels were associated with atherosclerotic heart disease in both men and women.[5-9] The effects of Lp(a) appear to be independent of the known effects of LDL cholesterol, high-density lipoprotein (HDL) cholesterol, and triglycerides.[10] The homology between apo(a) and plasminogen[11] has led to the speculation that Lp(a) may also be involved in disease mechanisms where atherogenesis and thrombosis are linked. The heterogeneous nature of Lp(a) and its skewed distribution in white subjects has been explained by variations in the apo(a) gene on chromosome 6, which is within the gene cluster for apo(a) and plasminogen (6q2.6 to q2.7).[12]

Lp(a) therefore appears to be a lipoprotein for which genetic constitution strongly predicts circulating levels. However, there is little information available as to the effects of life-style on levels, especially in women. We evaluated Lp(a) levels in two studies to further examine factors affecting its serum concentration. In the first, a cross-sectional study of older men and women, we evaluated the association between Lp(a) and cardiovascular disease risk factors. In the second we assessed the effects of exercise and estrogen therapy interventions on the Lp(a) levels of young postmenopausal women. Estrogen replacement therapy has been shown to reduce cardiovascular disease mortality.[13] In both studies we compared Lp(a) levels with levels of other lipids and lipoproteins. These two studies together pro-

*Mean ± SE.

vide data on the effects of age on the Lp(a) levels of postmenopausal women and provide an assessment of its usefulness as a marker of cardiovascular disease in women.

Material and methods

Study 1

Subjects. Seventy-five women and 105 men were recruited from a cohort of participants in an ongoing study conducted at Leisure World, a retirement community in Laguna Hills, California. The characteristics of this cohort have been described and validated previously.[14] Table I details ages of the individuals recruited for this study and their cardiovascular disease risk factors, which were documented by report and medical records. The subjects ranged in age from 64 to 88 years. Subjects who had a significant history, as diagnosed by a physician, of angina, myocardial infarction, stroke, or transient ischemic attacks were identified from the detailed questionnaire. Subjects with "heart problems" (Table I) included those subjects who had significant heart disease that was not specifically angina or a history of a previous myocardial infarction. Specifically excluded from this cohort were those subjects who were smokers or who had hypertension or diabetes mellitus. None of these subjects had received hormones or lipid-lowering medications in the past.

Protocol. Twenty milliliters of venous blood was obtained with the subject in a fasting state, between 8 and 10 AM. Sera were separated and stored at −20° C until analyzed.

Study 2

Subjects. Sixty-nine women who had undergone hysterectomy or hysterectomy and bilateral salpingo-oophorectomy, who were aged 40 to 55, and who were within 20% of their ideal body weight, were recruited and randomized by computer to one of four groups. Their postmenopausal status had been previously confirmed by elevated follicle-stimulating hormone levels and estradiol levels <25 pg/ml. No woman had any known medical illnesses. No woman had received exogenous hormones for at least 6 months. Subjects were randomized to one of four treatment groups: (1) a 6-month exercise regimen (n = 18), (2) a regimen of 0.625 mg of conjugated equine estrogen (Premarin) taken daily for 6 months (n = 19), (3) a 6-month regimen of conjugated equine estrogen therapy and exercise (n = 16), and (4) a regimen of 0.05 mg of transdermal estrogen (Estraderm) applied twice a week for 6 months (n = 16).

In groups 1 through 4, the ages, heights, and weights were similar as follows: mean ± SE ages 48 ± 1.3, 49.4 ± 1, 48.5 ± 1.3, and 48.1 ± 1.1 years, mean ± SE height 64.4 ± 0.5, 64.6 ± 0.4, 64.9 ± 0.5, and 64.8 ± 0.6 inches, and mean ± SE weight 138.6 ± 7, 142.6 ± 0.5, 144.5 ± 0.8, 143.1 ± 0.7 pounds.

No woman had hypertension or a history of thrombophlebitis, thromboembolic disease, or other cardiovascular disease risk factor. The women also had no current medical illnesses and were not receiving any medications.

For groups 1 and 3, a supervised exercise program was carried out at The Wellness Center, North Florida Regional Medical Center, Gainesville, Florida. This program consisted of walking on a treadmill for 15 minutes followed by pedaling an exercise bicycle for 15 minutes at between 70% and 80% of the maximal heart rate, three to four times per week for the entire 6 months.[15] This exercise regimen was shown to increase $\dot{V}O_2$max by 9% over 6 months.

Fasting blood was obtained from all subjects before enrollment in the study and after 6 months at the end of the regimen. All sera were stored at −20° C until analyzed.

Measurements. Lp(a) in serum was measured by an enzyme-linked immunosorbent assay obtained from

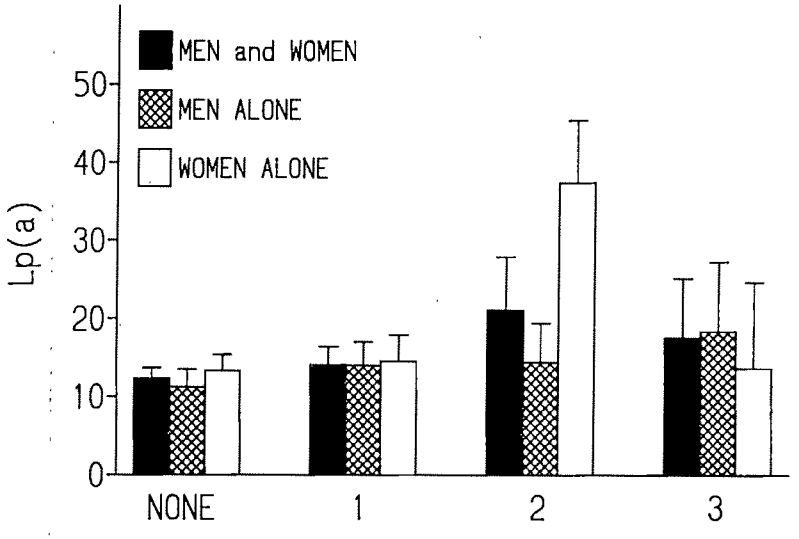

Fig. 1. Mean ± SE Lp(a) levels according to number of medical conditions (none, 1, 2, or 3) in men and women *(solid bars)*, men only *(hatched bars)*, and women *(open bars)*. Results of test for linear trend across categories adjusted for age: men and women, $p = 0.028$; men, $p = 0.103$; women, $p = 0.045$.

Table II. Mean ± SE blood lipids and lipoproteins (mg/dl) of subjects with no cardiovascular disease risk factors in study 1

Lipids	*Men (n = 44)*	*Women (n = 45)*
Age (yr)	75.9 ± 0.8	76.7 ± 0.8
Lp (a)	11.2 ± 1.7	13.3 ± 2.1
Apo A-I	192.0 ± 5.0	208.4 ± 4.3*
Apo B	101.9 ± 4.0	105.4 ± 3.5
Cholesterol	224.7 ± 7.0	254.4 ± 5.8*
Triglycerides	131.0 ± 8.9	148.5 ± 12.9
HDL	31.3 ± 1.6	39.7 ± 2.6*
LDL	168.3 ± 7.1	184.6 ± 6.1*
Cholesterol/HDL	8.2 ± 0.6	7.6 ± 0.5
Apo A-I/apo B	2.0 ± 0.1	2.1 ± 0.1

*Wilcoxon in rank sum test, $p < 0.001$.

Biopool, Hamilton, Ontario, Canada. This assay uses an affinity-purified polyclonal antibody raised against Lp(a) and a human standard obtained from the Blood Bank at Umea University Hospital, Sweden, and is a modification of the method of Guyton et al.[16]

Seventy-five white men and women, aged 22 to 55, were specifically recruited only to determine the precision and reproducibility of the Lp(a) assay in our laboratory. The mean ± SE serum Lp(a) level was 9.75 ± 1.23. The sensitivity of the assay was 0.1 mg/dl, and the intraassay and interassay coefficients of variation were 8% and 12%, respectively. Total cholesterol, triglycerides, and HDL cholesterol were carried out by well-established automated enzymatic procedures.[17-19] The HDL_2 subfraction was measured after precipitation by established methods.[20] LDL cholesterol was calculated with Friedewald's equation. Apo A-I and apo B were measured by immunonephelometric assays. Intraassay and interassay coefficients of variation of these measurements did not exceed 7% and 12%, respectively.

Statistical analyses. For study 1 the Wilcoxon rank-sum test was used to compare blood lipid and lipoprotein levels of men and women and of subjects with and without cardiovascular disease. Subjects were classified according to the number of medical conditions they reported at the time of recruitment into the cohort. A statistical test for linear trend in mean lipid and lipoprotein levels across categories on the basis of these categories was conducted with standard linear regression techniques. In study 2 the association between $\log_{10}$-transformed baseline measurements was assessed with Pearson product-moment correlation coefficients and standard linear regression techniques. The effects of treatment were assessed by repeated-measures analysis of variance. All p values reported are two-sided.

Results

Study 1. Lp(a) and other lipid and lipoprotein measurements were compared in men and women who reported no significant medical conditions (Table II). Serum Lp(a) measurements were similar in men and women, as were levels of apo B and triglycerides. However, total cholesterol, LDL cholesterol, HDL cholesterol, and apo A-I were all significantly higher in women than in men ($p < 0.001$). Ages were similar between the two groups. There was no effect of age on levels of Lp(a) in men or women within the limited age range of the study population. Only apo B correlated

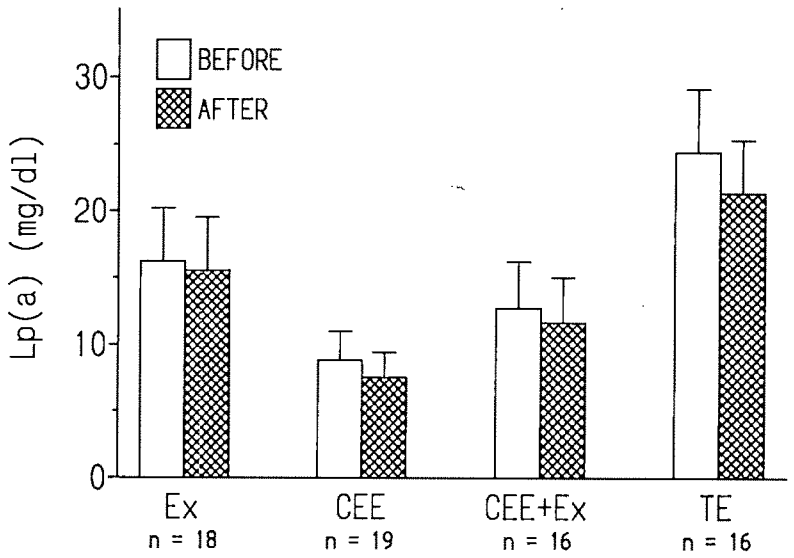

Fig. 2. Mean + SE Lp(a) levels in women before *(open bars)* and after *(hatched bars)* receiving various treatments for 6 months. *Ex*, Exercise; *CEE*, conjugated equine estrogen; *TE*, transdermal estrogen.

Table III. Mean ± SE values of Lp(a) (mg/dl) assessed for all subjects, men and women, with various conditions

Condition	*All*	*Men*	*Women*
None	12.3 ± 1.4 (n = 89)	11.2 ± 1.7 (n = 44)	13.3 ± 2.1 (n = 45)
Angina	16.8 ± 4.8 (n = 37)	12.8 ± 4.0 (n = 26)	26.2 ± 13.0 (n = 11)
Heart problems	13.8 ± 2.4 (n = 47)	13.4 ± 3.1 (n = 30)	14.4 ± 3.9 (n = 17)
Myocardial infarction	18.7 ± 5.6 (n = 33)	15.3 ± 4.4 (n = 30)	53.0 ± 45.6 (n = 3)
Stroke	18.2 ± 5.0 (n = 13)	12.7 ± 4.6 (n = 7)	24.5 ± 9.2 (n = 6)
Transient ischemic attack	35.0 ± 12.3 (n = 9)	39.1 ± 15.1 (n = 7)	21.0 ± 19.0 (n = 2)

negatively with age when men and women were combined ($r = -0.17$, $p < 0.02$) and in the male group alone ($r = -0.19$, $p < 0.05$).

Serum Lp(a) in these older men and women did not correlate with other lipid or lipoprotein parameters, with the exception of LDL ($r = 0.158$, $p = 0.04$).

Measurements of Lp(a) were analyzed on the basis of the medical conditions reported (Table III). In women Lp(a) measurements were higher when the history of angina, heart problems, myocardial infarction, stroke, or transient ischemic attacks was present. However, this relationship failed to achieve statistical significance. When all heart disorders were combined, the values were higher in women with these conditions than in those without disease (19.9 ± 6.0 vs 13.8 ± 2.1 mg/dl), but this result also did not achieve statistical significance.

For transient ischemic attacks, levels of Lp(a) were elevated in men and in women; this elevation was significant for men ($p < 0.05$). Similarly, when stroke and transient ischemic attacks were combined, the mean level of Lp(a) was 25.5 ± 6.4 in men and women combined (25.9 ± 8.4 in men and 24.5 ± 9.2 mg/dl in women) compared with 12.3 ± 1.4 mg/dl ($p < 0.05$) in those with no medical conditions.

Subjects were categorized according to the number of medical conditions they reported, and mean Lp(a) values were calculated for each group (Fig. 1). Tests were carried out to determine whether there was a linear trend in Lp(a) levels across categories with the use of regression analyses and with age in men, women, and the combined sample adjusted for (Fig. 1). A significant trend for increasing Lp(a) levels was noted as the number of conditions increased in the entire group ($p = 0.03$). In women alone, this relationship was also statistically significant ($p = 0.04$). In men, however, this relationship was only of borderline significance ($p = 0.10$).

Similar analyses were carried out for the measurements of apo A-I, apo B, cholesterol, triglycerides, HDL

cholesterol, LDL cholesterol, cholesterol/HDL cholesterol, and apo A-I/apo B ratios. No statistically significant trend was found for any of these measurements (data not shown). Only total triglycerides showed a marginal increasing trend with number of medical conditions for men ($p = 0.07$). The results for women were not significant ($p = 0.48$).

Study 2. In the 69 women before treatment, total cholesterol, HDL cholesterol, LDL cholesterol, and triglycerides averaged 226.4 ± 5.0, 62.2 ± 1.6, 150.8 ± 5.0, and 96.7 ± 4.8 mg/dl, respectively. Concentrations of serum HDL_2 cholesterol, apo A-I, apo B, and very-low-density lipoprotein (VLDL) were 15.2 ± 0.8, 169.1 ± 4.3, 83.9 ± 3.1, and 13.9 ± 1.1 mg/dl, respectively. Serum Lp(a) averaged 15.2 ± 1.8 mg/dl, but Lp(a) measurements varied significantly in the different groups at baseline. At baseline, Lp(a) did not correlate with any of the above parameters but showed a borderline negative correlation with HDL cholesterol ($r = -0.21$, $p = 0.08$).

The effect of various treatments for 6 months are depicted in Fig. 2. Exercise alone had a minimal and nonsignificant effect on Lp(a) (decrease of 2.5%). With estrogen, there was a 31.7% and a 26.9% decrease, respectively, for conjugated equine estrogen alone and for conjugated equine estrogen plus exercise and a 10.6% decrese associated with the use of transdermal estrogen alone. None of these differences was significant. Using repeated-measures analysis of variance and combining the two groups with conjugated equine estrogen together, the decrease in Lp(a) with treatment was of borderline significance ($p = 0.08$). The decrements in Lp(a), however, were not in those patients who had higher baseline values of Lp(a). In women who had Lp(a) values >10 mg/dl, Lp(a) decreased by only 8%, whereas in those women with baseline levels <10 mg/dl Lp(a) decreased by 37.8%.

Analysis of the changes in the other lipids and lipoproteins with treatment showed that exercise alone and transdermal estrogen did not affect any of the parameters (data not shown). After conjugated equine estrogen, in the groups without and with exercise, HDL cholesterol increased significantly by 14.9% and 13.9%, respectively (62.8 ± 2.8 to 71.8 ± 2.9 and 60.8 ± 2.4 to 69.1 ± 3.2 mg/dl, $p = 0.02$). The observed decreases in LDL cholesterol in these groups (13.1% and 11.1%) were not significant ($p = 0.18$) because of wide individual changes. However, triglycerides increased significantly by 40.6% and 48% from 92.6 ± 8.7 to 130.4 ± 12.2 mg/dl and 102.0 ± 9.8 to 153.3 ± 14.5 mg/dl, respectively ($p = 0.001$). VLDL concentrations also increased significantly by 49% and 51.7%, from 12.1 ± 1.6 to 19.3 ± 3.2 and 14.9 ± 3.1 to 20.6 ± 2.3 mg/dl, respectively ($p = 0.004$).

The observed, marginally significant decreases in Lp(a) levels with conjugated equine estrogen ($p = 0.08$) did not correlate with changes in HDL ($r = 0.02$) or LDL cholesterol ($r = 0.15$). However, after conjugated equine estrogen the changes in Lp(a) showed significant negative correlations with the increases in triglycerides ($r = -0.49$, $p = 0.001$) and VLDL ($r = -0.31$, $p = 0.06$).

Comment

Although Lp(a) was identified as a specific lipoprotein more than 20 years ago, little attention has been given to its clinical importance until recently. At present, its measurement is of considerable interest because of its apparent independent predictive value for cardiovascular disease risk. It has been reported that when Lp(a) levels in men are >30 mg/dl, the risk of myocardial infarction is increased twofold, and if Lp(a) and LDL are both increased, as compared with men with normal levels, the risk increases fivefold.[21] However, no study to our knowledge has specifically focused on this measurement in women. Although it has been known for some time that Lp(a) levels have a skewed distribution in white subjects and that levels are largely determined by genetic factors, we wished to examine closely the effect of sex, age, exercise, and estrogen on levels of Lp(a), focusing specifically on women.

Baseline levels of Lp(a) in women did not correlate well or consistently with any other lipids or lipoproteins we measured. In our first study Lp(a) correlated with triglycerides, and in the second group of younger women HDL cholesterol correlated in a negative direction with Lp(a). In the second study, with a statistical model created to explain the variation in levels of Lp(a) at baseline and based on other lipid and lipoprotein measurements, HDL cholesterol, followed by total triglycerides and cholesterol together could only account for 14.1% of the variability in Lp(a) levels. In these studies we showed that neither sex or age influenced levels of Lp(a).

Levels of Lp(a) were higher in men and women with stroke and transient ischemic attacks and were slightly higher when cardiac disorders were present. However, as the number of cardiovascular disease conditions increased, we observed a statistically significant trend of increasing Lp(a) levels. This effect was more striking for women than for men. Therefore these data are consistent with the notion that Lp(a) has a predictive value for cardiovascular disease in women. Because Lp(a) levels are known not to be affected by diet or the reduction in cholesterol with drug ingestion,[22-28] we suggest that measurements of Lp(a) may prove to be a valuable stable marker for the risk of cardiovascular disease.

Of considerable interest was the suggestion that levels of Lp(a) in patients with stroke and transient ischemic

attacks were of even greater predictive value than for cardiac disorders. Previous reports have linked measurements of Lp(a) with thrombotic stroke.[24] This is consistent with the physiologic feature of Lp(a) in that apo(a) and plasminogen have homology; elevated levels of Lp(a), by mimicking the role of plasminogen, may interfere with fibrinolysis,[25] thus promoting a particular propensity for thrombosis.

In this study we also wished to determine if life-style changes in women, such as exercise, would affect Lp(a) or if estrogen replacement could lower levels of Lp(a). This knowledge would be of importance for two reasons. First, we felt it would be important to determine if exercise or estrogen would potentially alter the predictive value of Lp(a). Cholesterol and triglyceride measurements, for example, are affected by both exercise and estrogen. Second, we wished to determine if these factors would lower Lp(a) such that, by so doing, a woman could potentially lower her risk of cardiovascular disease.

We found that exercise alone had no effect. Oral estrogen in the form of conjugated equine estrogen decreased Lp(a) levels somewhat ($p = 0.08$), but there was great variation in levels, which is in keeping with the known skewed distribution of Lp(a). Although the changes in the other lipids and lipoproteins were generally in the directions expected with the use of oral estrogen,[26] not all parameters achieved statistical significance, in part because of individual variation. However, the data suggest that oral estrogen may not be able to reduce the risk associated with high levels of Lp(a) because patients with higher values actually had the smallest changes in Lp(a) and the largest reductions in Lp(a) were seen in patients with low Lp(a) values.

The decrease in Lp(a) levels with conjugated equine estrogen use was significantly correlated with increases in triglycerides and VLDL. This suggests that oral, but not transdermal, estrogen may interefere somewhat with the synthesis of Lp(a) through a mechanism involved with synthesis of VLDL and triglycerides but not HDL. Lp(a) is known to be synthesized in the liver, and indeed messenger ribonucleic acid for Lp(a) has been detected in hepatic cell lines.[11, 12] These data support the concept that oral estrogen may have a minor influence on hepatic synthesis of Lp(a). Further elucidation of the mechanisms of this relationship may be important for understanding the physiologic metabolism of Lp(a).

In summary, Lp(a) levels appear to have no strong relationship to age, sex, or exercise and are primarily influenced by genetic factors involved in the synthesis of apo(a). By phenotyping apo(a) and identifying specific alleles, even more information may be forthcoming in the future. For example, it has been determined[10] that Lp^{S2} is associated with higher Lp(a) levels and higher cardiovascular disease risk as compared with Lp^{S4}, which is associated with low Lp(a) levels.

Discussion

Dr. Leon Speroff, Portland, Oregon (Fellow). Studies in the literature indicate that elevated levels of Lp(a) lipoprotein are associated with atherosclerotic heart disease in both men and women. What is intriguing is that this association is independent of the cholesterol-lipoprotein profile (although there is a weak correlation with triglycerides) and the familiar risk factors such as age and diet.[1] Lp(a) may be involved in both atherogenesis and thrombogenesis. The atherogenetic mechanism is similar to that of LDL: oxidative modification and uptake by the macrophage scavenger cell receptors in the intima of blood vessels. Thrombogenesis may be the result of the homology of Lp(a) with plasminogen, resulting in impaired fibrinolysis.

The purpose of this study was twofold:(1) to gather cross-sectional data seeking to confirm the lack of association between Lp(a) and cardiovascular disease risk factors and (2) to assess in women the effects of estrogen therapy and interventions in exercise habits.

Lp(a) was measured by an enzyme-linked immunosorbent assay technique and a purified polyclonal antibody. In the cross-sectional part of the investigation a random blood sample was assayed, and in the intervention part Lp(a) was measured before and after exercise or estrogen treatment. The results confirm findings in the literature of a lack of association between Lp(a) levels and sex and age and higher Lp(a) levels in men and women with cardiovascular disease factors. Exercise alone had no influence on Lp(a) levels, whereas oral and transdermal estrogen lowered Lp(a) levels, although the changes did not reach statistical significance. The authors concluded that the data are consistent with Lp(a) having predictive value for cardiovascular disease, and because estrogen had the smallest impact in women with the highest Lp(a) values, estrogen may not be able to affect the risk associated with Lp(a).

Lp(a) is a combination of LDL and two protein moieties, apo(a) and apolipoprotein B-100, which are covalently linked together. Apo(a) exists in different isoforms, varying in size and number. Lp(a) is also a glycoprotein, and because of its high carbohydrate content, it is soluble in aqueous media.[2] Like other glycoproteins, the carbohydrate component can vary. Therefore this structure has tremendous variability, and it is not surprising that measurements of this substance with one antibody in an immunoassay reveal great variability, up to 1000-fold between individuals, although levels remain relatively constant in the same individual. To compensate for this variability, studies must include large numbers of subjects. This probably explains the failure of the cross-sectional investigation to find significant elevations in men with cardiovascular disease factors. This variability between individuals is also important when an intervention study with before-and-after measurements is designed. Because levels are relatively constant within individuals, subjects should serve as their own controls. Group analysis, as performed in this study, would again require large numbers of subjects. In the intervention part of this study, the baseline Lp(a) levels differed greatly between groups, and the effect of estrogen did not reach statistical significance within each group. Perhaps larger numbers would have revealed some impact of exercise and, more likely, a greater effect of estrogen.

The description of methods did not specify with full accuracy how the subjects were chosen. Factors that affect cardiovascular disease need to be controlled to detect differences in one variable. Beside age and drugs, these factors include diet, level of fitness and body composition, past estrogen use, and the baseline lipid state. It is noteworthy that HDL levels were relatively high in the second part of the study, indicating a rather (cardiovascularly) healthy group of women. Estrogen treatment appears to have a greater impact on cardiovascular disease protection in women with risk factors and unfavorable lipoprotein profiles. An analysis of estrogen effect on Lp(a) should include sufficient numbers of women to stratify the impact according to risk factors and the lipoprotein profile. Because Lp(a) levels appear to be primarily genetically determined (i.e., not affected by diet and drugs), it can be argued that Lp(a) is a more stable marker and not influenced by the usual cardiovascular risk factors. Nevertheless, this must be documented.

The actual levels of Lp(a) measured are a little concerning. In general the literature indicates that relatively high levels of Lp(a) must be present to indicate an association with cardiovascular disease, and only 10% to 15% of the white population carry pathologic levels of Lp(a).[3-6] In one study levels had to be >365 mg/dl to have twice the rate of coronary heart disease.[7] The mean levels in this study range from 11.2 to 53 mg/dl. The group means in the second part of the study were relatively low. Again these differences probably reflect the great variability in Lp(a), and they underscore the need for large numbers of subjects. Although this study indicated the greatest impact of estrogen in women with lower Lp(a) levels, it is unlikely that this study included any women with very high

levels, levels with the strongest correlation wtih cardiovascular disease.

In spite of the difficulties, this is an important contribution. It has been suggested that Lp(a) ranks with the HDL/total cholesterol ratio as the best predictor of coronary artery disease.[8] This study reinforces the observation that genetically determined plasma levels of Lp(a) have predictive value for cardiovascular disease, and this is, to my knowledge, the first investigation of the impact of estrogen.

Dr. Norman Gant, Dallas, Texas. One of the questions that came to mind concerns the very low values for Lp(a) that you observed in the older patients. Were they not in fact values obtained in the survivors? Had they not already preselected themselves? Those with higher levels possibly had already died before getting to "vacation village."

I was just wondering if you've had an opportunity to look at younger, middle-aged men who might be more at risk. In other words, have you looked at some younger people who haven't yet canceled themselves out of the study?

Dr. Howard L. Judd, Los Angeles, California. We've just finished a multicenter study in which we looked at lipids with various estrogens. The responses of the lipids to hormonal manipulation were influenced by the baseline level. If the HDL was low, then the response was greater than when the HDL was high, and the opposite was true for LDL. Did you have an opportunity to look at baseline levels and check responses of your lipids in regard to manipulations that you observed?

Dr. Frederick Naftolin, New Haven, Connecticut. The evidence that exercise can have a measurable impact on the outcome of a woman's life at the point we are examining is decreasingly small, if at all visible. I think that we shouldn't lose this opportunity to see that here again is evidence that genetic constitution and hormonal levels are the primary motivators of such things as cardiovascular risk. We shouldn't lose the opportunity to see the futility of advising elderly women to undertake exercise regimens to determine the outcomes of their cardiovascular lives.

Dr. James M. Roberts, San Francisco, California. I have to object to one of your statements—unless I misread the data. You stated that there was a close correlation between triglycerides and Lp(a) levels. The r values I saw was 0.22; thus R^2 is 0.04, which means that only 4% of variation could be accounted for by the relationship, which doesn't seem to me to be a high correlation.

Dr. Lobo (Closing). To answer Dr. Speroff's first question, the acknowledged variability in the levels of Lp(a) is not really an assay problem. It is really a genetic trait that determines the levels of Lp(a) because of various phenotypes of apo(a).

I would have preferred to incorporate more patients into both studies. Nevertheless, in the literature those studies that have reported the different ranges of odds ratios for the association of Lp(a) levels with cardiovascular disease have had numbers of patients in the same range that we have reported here.

The difficulty in these types of studies is that there is greater variability in Lp(a) levels because of differences in the genetic background. A skewed distribution of values occurs in white subjects. However, this does not occur in black persons who, for example, have a nice bell-shaped distribution. So my contention is that it is actually quite difficult to carry out studies on Lp(a) because of its variability.

However, one should note that in spite of this we saw a positive trend in the Leisure World cohort, between an increasing number of medical conditions and higher levels of Lp(a). This was significant in both men and in women. We didn't see these trends, however, for what are known to be established risk factors such as apo A-I, LDL, and HDL. In this model you could almost argue that Lp(a) values were actually better than the established risk factors.

I think Dr. Gant is absolutely right. It was our conclusion that the individuals at greatest risk had died. We were studying a healthier survivor population where we still see some semblance of Lp(a) constituting a risk, but our study does not address the risk of the man who is 45 years old and has had three myocardial infarctions. Because of the variation in Lp(a) levels, I think the future in this field is really to specifically identify apo(a) phenotypes. For example, by measuring the S-2 phenotype as opposed to the S-4 phenotype where the levels are higher, one could pick up about 14% of the white population who have this trait. Those would be the people to identify who are at risk for thrombosis and atherogenesis related to lipoproteins.

Dr. Speroff asked me about selection of the variables and selection of patients. In the cross-sectional study the subjects were closely matched, particularly by age,

and had no other confounding diseases such as diabetes mellitus or hypertension. The baseline lipoprotein measurements are typical of what has been reported for men and women.

In our prospective study the younger individuals were specifically screened for not having risk factors because we wished to assess life-style variables. So this was a very fit, young, healthy population. Diet was controlled and no estrogen was being used. The high HDL levels at baseline really confirm the subjects' cardiovascular health. We therefore wished to study if exercise or estrogen would alter Lp(a) levels in this healthy population.

Indeed, our conclusion here is that within an individual Lp(a) is a very stable marker. Estrogen probably does influence Lp(a) levels but only by a minor degree. Exercise does not appear to have an effect. So it really reflects one's inherent propensity for cardiovascular risk.

Again, I thank Dr. Gant for his very intuitive insight. I agree with him. We were dealing largely with a survival population. Dr. Judd had a question related to baseline variability. In our manuscript we have actually included these data. Whereas the influence of baseline values is probably true for changes in HDL and LDL, this was not the case for changes in Lp(a). We looked at those patients with higher values and lower values and saw the same magnitude of borderline change in the two groups for Lp(a).

Dr. Naftolin, I think the question on exercise is still open to debate. I understand there is controversy in this area, but again we felt that in this model Lp(a) was not influenced by exercise.

For Roberts' comments challenging the concept of VLDL, triglyceride, and Lp(a) changes, indeed these are matching correlative analyses, and the statistics were not strong, although changes were significant because of the larger sample size. The point we're trying to make is that because the complementary deoxyribonucleic acid for apo(a) has been constructed from a hepatic library of ribonucleic acid, suggesting that apo(a) production is hepatic in origin, we feel that some common hepatic metabolism may be involved with these lipoproteins. I guess I could be challenged enough to say that these associations remain speculative.

Lipid and apolipoprotein abnormalities in hirsute women

I. The association with insulin resistance

Robert A. Wild, MD,[a] Petar Alaupovic, PhD,[b] and Ivy J. Parker, BS, RN[a]
Oklahoma City, Oklahoma

OBJECTIVE: We attempted to evaluate apolipoprotein lipid levels in hirsute hyperandrogenic women and to clarify the influence of insulin resistance versus endogenous sex steroids on these profiles.
STUDY DESIGN: Forty-seven women seen for evaluation of hirsutism in the Reproductive Endocrine Clinic were contrasted with 15 normal women. Thirty-one patients were treated with the gonadotropin-releasing hormone analog, leuprolide acetate, 7.5 mg intramuscularly monthly for 3 months. Insulin resistance was assessed before and after GnRH analog administration. Mean concentrations were compared with the Student *t* test and analysis of variance.
RESULTS: Hirsute women were heavier and had higher systolic and diastolic blood pressures, more menstrual irregularities (all $p < 0.01$), and higher waist/hip ratios ($p < 0.05$). They had higher triglyceride, very-low-density lipoprotein cholesterol, and apolipoprotein C-III levels and lower high-density lipoprotein cholesterol concentrations (all $p < 0.01$). They had lower apolipoprotein A-I/A-II ratios ($p < 0.01$). After administration of GnRH analog, androgen and estrogens were suppressed and insulin resistance was unaltered. Insulin correlated with apolipoprotein lipid abnormalities.
CONCLUSION: Lipid and apolipoprotein abnormalities in these hirsute women seem to be associated more with insulin resistance than with endogenous androgens or estrogens. (AM J OBSTET GYNECOL 1992;166:1191-7.)

Key words: Insulin resistance, gonadotropin-releasing hormone analog, hirsutism, apolipoprotein

Hirsutism and acne are clearly more than cosmetic concerns.[1] These physical features, expressions of androgen excess,[2,3] signal metabolic aberration.[1,4] Women with polycystic ovary syndrome, the most common endocrine disorder associated with hirsutism, have insulin resistance whether or not they are obese.[4,5] They frequently have male pattern obesity,[6,7] higher levels of free testosterone than normal women,[1,7] and less favorable lipoprotein lipid levels in plasma.[8] All of these are risk factors for coronary vascular disease in women.[9,10]

To investigate one of the cardiovascular risk factors present in women with hirsutism, we began studying their lipid metabolism.[1] We have found that they have higher concentrations of triglycerides and lower concentrations of high-density lipoprotein (HDL) cholesterol than normal women, even when matched for body weight.[1,8] By cross-sectional analysis in a separate population, these altered levels of lipoprotein lipids have been found to be associated independently with both androgen and insulin excess.[7] In an attempt to differentiate between these two possible effects, a group of hirsute women was tested with gonadotropin-releasing hormone (GnRH) analog to remove the possible effect of endogenous gonadal hormones. Results of this intervention study show that insulin or insulin resistance exerts a greater effect than gonadal hormones on the levels of lipids and apolipoproteins in plasma of hyperandrogenic women.

Subjects and methods

Patients. Forty-seven women complaining of hirsutism were evaluated by history, physical examination, and determination of sex steroids, fasting lipoprotein lipids, apolipoproteins, and parameters of insulin resistance. They were compared with a control group of 15 nonhirsute, regularly menstruating women sampled in the proliferative phase of the menstrual cycle. Patients with Cushing's syndrome, hypothyroidism, androgen-secreting tumors, or prolactinomas were excluded. All women had documented hyperandrogenism, defined as an increased level of one or more of the following: free and albumin-bound testosterone,

dehydroepiandrosterone sulfate (DHEAS), or androstenedione. All women were in excellent general health. For 3 months before the study none had taken any medications known to affect pituitary-gonadal function or carbohydrate or lipid metabolism. Smokers were excluded. Women with blood pressure >140 mm Hg systolic or >90 mm Hg diastolic were excluded. None consumed excessive amounts of alcohol, and none were vegetarians or eating any other special diet. Diet history, exercise frequency, and family history of cardiovascular disease were recorded and scored for each patient as described previously.[1] Hirsutism was graded as reported by Ferriman and Gallwey. Acne was graded as recorded by Pleiwig and Kligman.[1] Obesity was defined as >120% ideal body weight according to current Metropolitan Life Insurance Company tables. If the 17α-hydroxyprogesterone concentration was >2.0 mg/ml, a corticotropin stimulation test with 25 μm corticotropin was performed. 17α-Hydroxyprogesterone was measured at baseline and at 60 minutes to rule out 21-hydroxylase deficiency.

Thirty-one hirsute women were given GnRH analog (Lupron Depot, 7.5 mg intramuscularly, Tapp Pharmaceutical, Chicago) and were reevaluated in a fashion identical to baseline after 3 monthly injections of GnRH analog. This study was approved by the Institutional Review Board of the University of Oklahoma Health Sciences Center.

Insulin resistance. Insulin resistance was determined by an intravenous bolus of 0.1 U/kg of regular insulin and determination of glucose disposal.[11]

Sex steroids and glycoprotein hormones. Serum follicle-stimulating hormone, luteinizing hormone, testosterone, unbound testosterone, sex hormone–binding globulin, DHEAS, androstenedione, and estradiol were analyzed by radioimmunoassay by well-established, previously reported methods.[7] When serum estradiol was below the low sensitivity of the assay (20 pg/ml), it was assigned a value of 20 for statistical analysis.

Glucose, insulin, C-peptide. Glucose was measured

with a Beckman glucose analyzer II (Brea, Calif.). Insulin and C-peptide was measured by radioimmunoassay, again by previously reported methods.[7] Interassay variation was ≤9%.

Lipids, lipoprotein cholesterol, and apolipoproteins. Plasma total cholesterol (CHOP/PAP, Boehringer, Mannheim, Germany) and triglyceride (kits for total triglyceride and free glycerol, Abbott Laboratories, Diagnostics Division, Irving, Tex.) concentrations were determined enzymatically on an Abbott VP-Super System analyzer. Both assays were standardized with serum calibrators and control samples supplied by the Centers for Disease Control, Atlanta. Cholesterol contents of very-low-density (VLDL), low-density (LDL), and HDL lipoproteins were measured according to the procedures of the Lipid Research Clinics Program. Apolipoprotein analyses were carried out by electroimmunoassays as previously described[12] for apo A-I and apo A-II, apo B, apo C-III, and apo E. Apo C-III was measured in whole serum and in heparin-precipitated and heparin supernate lipoproteins. The heparin-precipitated (VLDL and LDL) and nonprecipitated (HDL) lipoproteins were isolated by a modification of the heparin-Mn^{++} method in that a Mn^{++} concentration of 0.092 mol/L was used instead of 0.046 as originally described. The apo C-III heparin supernate/heparin-precipitated apo C-III ratio represents a useful criterion for assessing the efficiency of triglyceride-rich lipoprotein degradation.

Statistics. Mean concentrations were compared by the Student t test and analysis of variance. Triglyceride and fasting insulin value were logarithmically normalized before analysis. Pearson product moment correlation coefficients were computed. All computations were made with SAS (Statistical Analysis Systems, Inc., Cary, N.C.). Significance was set at $p < 0.05$.

Results

Clinical parameters of the hirsute women contrasted with controls are shown in Table I, and their average hormone concentrations are contrasted in Table II. As expected, we found that the hirsute women were heavier and had higher systolic and diastolic blood pressures, higher waist/hip ratios, and more menstrual irregularity. We documented higher concentrations of androgens (androstenedione, testosterone, unbound testosterone, and DHEAS). We found significantly higher concentrations of plasma triglycerides, VLDL

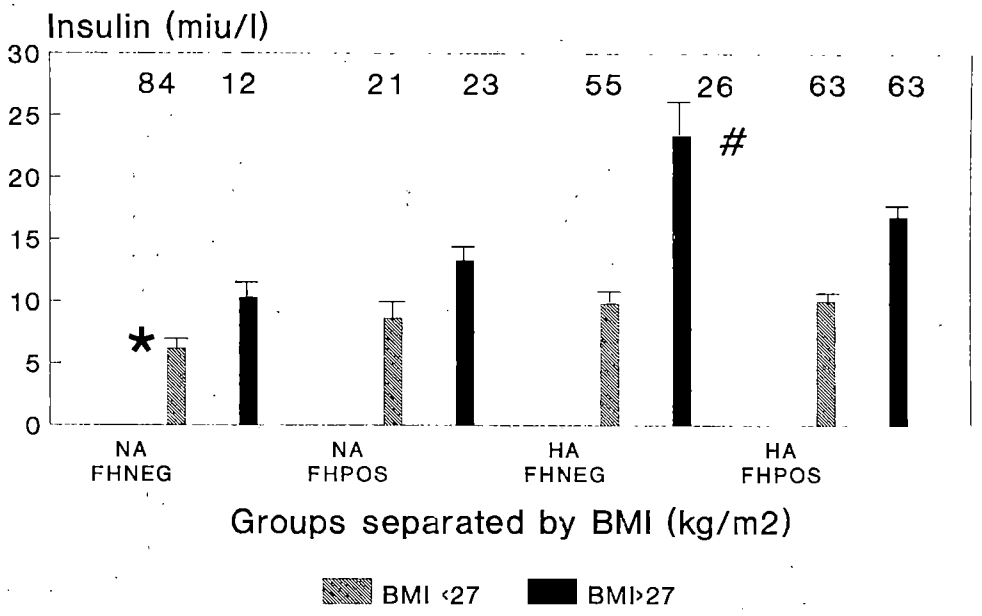

Fig. 1. Fasting insulin concentrations in 204 hyperandrogenic *(HA)* and 140 case-control women *(NA)*, stratified by body mass index *(BMI)* and family history of diabetes *(FHNEG, FHPOS)*. *Number symbol*, $p < 0.01$, against other groups; *asterisk*, $p < 0.01$, against all other groups.

Table VII. Correlation of logarithmically normalized fasting insulin and unbound testosterone with lipoprotein lipids, apolipoproteins, and glucose before and during GnRH analog in hirsute women

	Logarithmically normalized fasting insulin		*Unbound testosterone**	
	Baseline	*GnRH analog at 3 mo (p value)*	*Baseline*	*GnRH analog at 3 mo (p value)*
Fasting glucose	0.50 (0.004)	0.42 (0.02)	0.30	0.19
Logarithmically normalized triglycerides	0.34 (0.06)	0.59 (0.0001)	0.22	0.31
VLDL cholesterol	0.22 (NS)	0.51 (0.006)	0.07	0.13
Apo C-III	0.22 (NS)	0.38 (0.05)	0.07	0.08

cholesterol, and apo C-III and significantly lower levels of HDL cholesterol in the hirsute women compared with the normal women (Table III). They were also found to have lower levels of apo A-I and higher levels of apo A-II with a resulting significantly lower apo A-I/apo A-II ratio than control subjects (Table III).

After 3 months of GnRH analog treatment, there was a significant suppression of androgen and estrogen levels (Table IV), but there were no significant changes in average lipid, lipoprotein cholesterol, and apolipoprotein concentrations (Table V). In contrast to significant changes in the plasma levels of gonadal hormones, the insulin resistance remained unaltered after 3 months of GnRH analog treatment in the hirsute women (Table VI). Average body weight was unchanged during treatment. Correlation coefficients between logarithmically normalized fasting insulin concentrations and altered lipoprotein and apolipoproteins are contrasted with correlations between unbound testosterone and the same lipid parameters both before and at the end of the third month of GnRH analog in Table VII. Correlation coefficients were stronger between logarithmically fasting insulin and triglycerides, VLDL cholesterol, apo C-III, apo B, and heparin-precipitated apo C-III after 3 months of treatment.

Comment

We have confirmed that hirsute hyperandrogenic women have lower HDL cholesterol and higher triglyceride and VLDL cholesterol concentrations than

normal women, and we have expanded our observations to demonstrate that they also have unfavorable apolipoprotein profiles. We have used an analog of GnRH as a powerful research and therapeutic tool to remove endogenous ovarian androgen and estrogen production to observe the subsequent effects of removal of gonadal hormones on lipoprotein and apolipoprotein metabolism. We observed, as has been reported previously,[4, 5] that insulin resistance accompanied by elevated fasting insulin levels and delayed glucose disposal is common when hirsutism is present. We found, as has been documented, no apparent effect of GnRH analog on either adrenal androgen production or insulin resistance after 3 months of suppression of the hypothalamic-pituitary-gonadal axis.[13-15]

The abnormalities in plasma levels of triglyceride-rich lipoprotein constituents and HDL cholesterol, previously shown to be correlated with androgens and insulin,[7] seem to be associated more with insulin resistance than with plasma levels of androgens and estrogens. Their lipid and apolipoprotein profiles demonstrate the same pattern as that seen in other states of insulin resistance with varying degress of glucose tolerance.[16] The fact that these profiles are unaltered during GnRH analog therapy, although parameters of insulin resistance were unchanged, suggests that insulin has a more powerful influence on lipid and apolipoprotein metabolism in hirsute women than does either endogenous gonadal androgen or estrogen.

In this study we noted that most women had good ovarian suppression by the analog (average estradiol concentration on GnRH analog was near castrate levels), but in spite of this the average testosterone concentrations remained at the upper limits of or slightly above normal. This is probably a reflection of testosterone's origins from adrenal production or peripheral conversion of its precursors. We cannot rule out an effect of either gonadal estrogen or androgen on lipid metabolism in these patients; however, we can conclude that if there is an effect of either of these hormones, the effects seem to be overshadowed by the effect of elevated insulin found as a consequence of concurrent insulin resistance. A careful inspection of Table VII reveals that the association of fasting insulin with the lipid parameter becomes stronger after the influence of gonadal hormones is removed.

Recent evidence favors a powerful influence of insulin on ovarian androgen production. Both androgen and insulin may be important contributors to the problems of hirsutism[2, 17] and possibly acne through its action on insulin-like growth factor-I receptors.[17] Insulin excess associated with insulin resistance is linked both to elevated blood pressure and to upper-body-segment obesity.[18] Both of these are well-known risk factors for cardiovascular disease.[10] Women with polycystic ovary syndrome, the most common endocrinopathy associated with hirsutism, are prone to each of these abnormalities.[7]

Because some triglyceride-rich lipoproteins may have significant atherogenic potential,[19, 20] hirsute hyperandrogenic women need to be evaluated for this and other cardiovascular disease risk factors. Further evaluation of androgenized women may shed light on mechanisms for altered cardiovascular risk and may improve our understanding of reasons for the earlier onset and greater incidence of cardiovascular disease in men compared with women.

We thank Johnelle May for her concern for our patients and Lisa Harris for her expert technical assistance.

Discussion

Dr. Brian A. Little, Montreal, Quebec, Canada (Fellow). More and more, polycystic ovarian syndrome and hirsutism are becoming mere manifestations of more complex metabolic diseases. Dr. Wild and his colleagues have added one more small piece to the puzzle. By the suppression of gonadotropin secretion through the administration of a GnRH agonist (leuprolide acetate [D-Leu^6, Pro^9-Het^{10}]), they have demonstrated that both lipid abnormalities and insulin resistance persisted in the face of reduced androgens. Although testosterone and androstenedione levels were reduced, they remained in the normal range. The DHEAS concentration was unchanged, remaining high.

Although there are some small niggling questions I have, most of my remarks will be to add support to the data and ask for comments on my interpretation of the data as they fit into the overall complex metabolic process.

First the questions: I noticed the clinical characteristics of the hirsute group included a weight differential of 75 pounds, the hirsute group averaging 204 pounds (normal 129) with a significantly greater waist/hip ratio (0.81 to 0.73). In spite of the fact that you have classified obese patients as those with >120% ideal body weight, how much did this obesity contribute to the results? If, for example, they are included in the hirsute group, it is well known that many of them have primary or marginal metabolic disease, e.g., abnormal carbohydrate metabolism or family history of diabetes and lipid abnormalities. For this reason it would be helpful to know what proportion of the group studied were obese or had a family history of diabetes Did you do any carbohydrate metabolism tests on your normal patients?

The heterogeneity of the study group is also manifest by the failure of the GnRH agonist to reduce the androgens (testosterone and androstenedione) below the normal level. This could be a function not only of the patient selection but also of the GnRH agonist used (leuprolide). For example, it could be that pharmacologic variants act somewhat differently. Nafarelin [D-Nal(2)^6], which is more potent, albeit when given in small doses (200 μg) intranasally to patients with polycystic ovary syndrome twice daily for 6 months, suppressed androgen levels below normal.[1] (This is all in the interest of explaining some of the problems that make this so complex.) What is Dr. Wild's view of the effect of different GnRH agonists and do they act differently on different tissues (e.g., pituitary, ovary, or adrenal)?

Fig. 1 shows another part of this intricate relationship. This is the comparison of fasting insulin concentrations in 204 hyperandrogenic women and 140 case controls, stratified by body mass index and family history of diabetes. In Fig. 1 fasting insulin is on the axis and the ordinate shows women grouped by body mass index of <27 kg/m^2 or >27 kg/m^2 with a negative or positive family history of non-insulin-dependent diabetes mellitus (confirmed by interview with the family) in nonandrogenic (case control) or hyperandrogenic patients (defined by a hirsutism score >16 or a testosterone value >1 SD above a group of normal fertile women). It can be seen that overall hyperandrogenic women had higher fasting insulin levels than did the control group, and family history–positive control women had higher values than their family history–negative counterparts. In women of normal weight (body mass index <27 kg/m^2) family history of diabetes mellitus made no difference in that the family history–positive control group was the same as the family history–positive and family history–negative hyperandrogenic group, except that only the family history–negative control group had lower fasting insulin levels than all others. Finally, obese women (body mass index >27 kg/m^2) who were family history negative had higher fasting insulin levels than any other group including both family history–positive hyperandrogenic and control women and family history–negative control subjects. In addition, Morris et al.[2] have gone on to show that abnormalities in serum lipoprotein concentrations in hyperandrogenic women are a reflection of the metabolic derangements associated with obesity.

If one could broadly equate fasting insulin with insulin resistance (and in this group the sum of insulin concentrations during an oral glucose tolerance reflected the findings for fasting insulin and equally relate such resistance to lipid abnormalities, I wonder if one would expect an effect of GnRH analog?

In any event, I congratulate Dr. Wild on making the most of a difficult result and would suggest to you all that at last we have a reason to take a family history. For I find that in patients with problems of abnormal cycling, infertility, and polycystic ovary syndrome, I have great success with the questions, "Are there sugar problems in the family? . . . Is there any heart disease? . . . What about hypertension?" The relationship between the first two have been addressed thoughtfully today. I predict the next abnormality to be related in this way may be hypertension, related in some way to the adrenal gland and kidney. As to what to do for such

genetic abnormalities, perhaps we shall hear more in the next meetings.

Dr. Wild (Closing). Dr. Little, you addressed a number of areas, and I would like to share with you some of my personal observations and biases.

The first issue was an important one. What about the contribution of obesity to the entire process? There is no question of the independent effect of obesity on all the alterations that were seen. It's difficult to ferret out the independent effects of obesity, but what I would like to point out is that most studies that look at patients with polycystic ovary syndrome who are not obese find over and over again insulin resistance.

What's difficult to sort out when these evaluations are done is what is the role of diet interaction as well as the other potential confounder that you presented, the intriguing concept of family history as it relates to the entire process.

You brought up concerns—the bane of the existence of all of us that are interested in androgen disorders—the problem of heterogeneity. It's a constant problem, and I think it's important to realize that the insights we addressed here applied only to the population observed. There is no unanimity of definition of what the polycystic ovary syndrome really is, so we have to be careful to describe the exact population of inference. It is a heterogeneous disorder. Within the group seen, I'm sure there are significant endocrinopathies that can be discerned with further testing. I would like to point out that our study was an interim analysis. This was our first opportunity to arrive at power for inference. As numbers go up and as this protocol becomes modulated, maybe we can get better insight into those questions that are right now limited by power. The most important questions will be addressed by subgroup analysis; in our minds, in particular, the effect of adrenal androgen contribution versus ovarian androgen contribution.

You asked about the agonists and if they act differently. I don't have good data to relate to you, but it's my feeling that some of the reasons that these androgens came down close to normal but were not completely suppressed may be from the fact that there is a significant adrenal contribution that was not affected. This illustrates the beauty and specificity of the GnRH analog to begin to dissect out these questions. Another explanation is the issue of body weight and dose-response studies for the GnRH agonists. There is one article in the literature to my knowledge that looks at this with daily subcutaneous GnRH treatment, and it suggests that if dosages are adjusted for body weight, better suppression occurs. If the suppression is carried out >3 months, you may still get more suppression. We haven't been able to observe this effect as yet.

Your observations of family history data are very intriguing. It fits my bias that the interaction of dietary saturated fat with genetics may well be the prime mover in terms of aggravation of this phenomenon. You're absolutely right that interaction between insulin and blood pressure and the understanding of how they interact are exciting. Syndrome X is the pathophysiologic related condition, and as investigations continue, I think we can look forward to exciting inferences.

Elevated maternal plasma corticotropin-releasing hormone levels in pregnancies complicated by preterm labor

Wendy B. Warren, MD, Sharon L. Patrick, MD, and Robin S. Goland, MD
New York, New York

OBJECTIVES: We investigated whether maternal plasma evels of the placental hormone corticotropin-releasing hormone are elevated in pregnancies complicated by preterm labor.
STUDY DESIGN: Mean maternal corticotropin-releasing hormone levels were studied in women who met specific criteria for preterm labor anc in women with normal pregnancies. Levels were also compared in the latent and active phases during term labor.
RESULTS: In pregnancies complicated by preterm labor, maternal corticotropin-releasing hormone levels were higher than in normal pregnancies; this elevation occurred before labor was diagnosed clinically ($p < 0.05$). When preterm labor was associated with infection, the mean levels were not elevated. Mean plasma levels were similar in latent and active phases during labor at term.
CONCLUSION: Maternal plasma corticotropin-releasing hormone levels are elevated in association with preterm labor. This elevation does not appear to be due to labor itself and may reflect an early activation of the placenta before the onset of preterm labor. (Am J Obstet Gynecol 1992;166:1198-207.)

Key words: Corticotropin-releasing hormone, preterm labor, placenta, fetus, hypothalamus, pituitary, adrenal

The hypothalamic hormone corticotropin-releasing hormone (CRH) is synthesized by human trophoblast, amnion, chorion, and decidual cells,[1] and placental CRH is secreted into maternal and fetal plasma during pregnancy.[2-5] Although CRH is present at extremely low levels in the plasma of nonpregnant adults, levels rise throughout the second and third trimesters, increasing exponentially in the final 6 weeks before parturition at term.[3,4,6] Concentrations of CRH messenger ribonucleic acid in the placenta parallel this well-described pattern of secretion.[7]

Evidence from in vitro and in vivo studies suggests that placental CRH is biologically active and stimulates the pituitary-adrenal axis during pregnancy.[3,8,9] In contrast to hypothalamic CRH, which is suppressed by glucocorticoids, secretion of CRH by trophoblast cells is stimulated by glucocorticoids in vitro,[10,11] suggesting a positive feedback between the fetal pituitary-adrenal axis and placental CRH. According to this model, progressive stimulation of all the compartments of the placental-pituitary-adrenal axis may culminate in parturition.[10]

CRH release by trophoblast cells in culture is stimulated by oxytocin.[12] In addition, CRH increases prostaglandin E_2 and $F_{2\alpha}$ production by trophoblast and fetal membrane cells in vitro.[1] It has been shown that CRH increases the contractility of myometrial cells in the presence of oxytocin in vitro.[13] In view of these studies, some investigators have suggested a role for placental CRH in the mechanisms of human parturition.[10,12,13]

Because placental CRH may be involved in mechanisms leading to labor, we studied it in pregnancies complicated by preterm labor and during normal term labor. We hypothesized that the rise in maternal plasma CRH levels that precedes normal parturition at term occurs early in pregnancies complicated by preterm labor. The purpose of these studies was to determine whether (1) maternal plasma CRH levels are elevated during preterm labor, (2) levels are elevated when preterm labor is associated with infections, (3) levels are higher than normal before the onset of preterm labor, (4) levels remain elevated after suppression of uterine contractions with tocolytic agents, and (5) levels rise during normal term labor.

Material and methods

The end point for entry into the studies investigating maternal plasma CRH levels in association with preterm labor was identification of preterm labor rather than preterm delivery. We used criteria for the diagnosis of preterm labor as defined by Creasy,[14] including uterine contractions before 37 completed weeks of gestation in the presence of progressive cervical dilatation,

effacement, or rupture of membranes. Gestational age was determined for all fetuses by the history of the last menstrual period and first-trimester clinical examination. Confirmation by ultrasonographic examination was obtained for all patients diagnosed with preterm labor and in normal pregnancies as indicated. Treatment decisions were made by the patients' physicians in all cases and were not affected by participation in these studies. Signed informed consent was obtained from all subjects. These studies were approved by our institutional review board. In all studies a significance level of $p < 0.05$ was used. Data are presented as mean ± SEM.

Women admitted to the labor suite for treatment of preterm labor. We obtained a single venous blood sample from 39 women between 24 and 36 weeks of gestation admitted to our labor and delivery suite for treatment of preterm labor. In 34 cases blood samples were obtained before initiation of any medications. However, in five cases infusions of magnesium sulfate had been started before samples were obtained. The mean plasma CRH level in the women after magnesium infusion was not different from that in the rest of the women, and therefore these data were combined. In no cases were glucocorticoids given before blood samples were obtained.

The mean maternal plasma CRH concentration for women with preterm labor was compared with that for a group of normal nonlaboring pregnant women at the same gestational ages, by use of two-way analysis of variance.

Preterm labor associated with infections. All women admitted for treatment of preterm labor were evaluated for evidence of associated infections. In nine women admitted between 24 and 36 weeks of gestation, associated clinical infections were identified. These infections included chorioamnionitis and asymptomatic bacteriuria. Diagnosis of chorioamnionitis was made with previously described criteria, including maternal fever (≥38° C), maternal or fetal tachycardia, uterine tenderness, leukocytosis, and foul odor of the amniotic fluid, in the absence of other identified infection.[15] Placental pathologic studies were used when available to confirm the clinical diagnosis. Asymptomatic bacteriuria was diagnosed on the basis of a single urine culture with a colony count of 10^5/ml urine of a single organism.

The mean maternal plasma CRH levels for women with preterm labor both with and without infections were compared with the mean concentration for women with normal pregnancies by analysis of variance. The Student–Newman-Keuls post hoc test was applied to evaluate the differences in mean maternal plasma CRH levels between groups.

Women monitored prospectively for risk of preterm labor. To investigate maternal plasma CRH levels in women before preterm labor developed, we obtained venous blood samples from 17 women between 29 and 36 weeks of gestation who were identified to be at risk for preterm labor and referred to our high-risk antepartum clinic. Identified risks included previous premature delivery ($n = 15$), diagnosis of uterine didelphys ($n = 1$), and enlarging uterine myomas ($n = 1$). Eight women in the group subsequently had preterm labor, whereas nine had uncomplicated courses and were delivered at term. In some women we obtained more than one blood sample between 29 and 36 weeks of gestation. For statistical analysis, the mean CRH concentration of these multiple samples was used. The mean maternal plasma CRH levels for these groups and the mean level of CRH in women with normal pregnancies between 29 and 36 weeks of gestation were compared by analysis of variance with the Student–Newman-Keuls post hoc test of significance.

Women followed up after treatment for preterm labor. We studied 10 women who had been treated for preterm labor but who were not delivered prematurely. All of these women were being treated with oral terbutaline. Venous blood was obtained from these women at 29 to 36 weeks of gestation. The mean plasma CRH concentration for this group after preterm labor was compared with the mean level for the control group of women with normal pregnancy at the same gestational age by unpaired t test.

The effect of term labor on maternal plasma CRH levels. To study the effects of labor itself on maternal plasma CRH concentrations, we obtained venous blood samples from six women in both the latent phase (cervical dilatation <3 cm) and the active phase (dilatation >5 cm) of normal labor at 37 to 40 weeks of gestation. Mean maternal plasma CRH levels for each woman in latent and active labor were compared by paired t test.

Women with normal uncomplicated pregnancies. Venous blood samples were obtained from 30 women monitored in our routine antepartum clinics between 24 and 36 weeks of gestation. These women had normal uncomplicated pregnancies and subsequently were delivered at term.

CRH radioimmunoassay. Blood was collected in tubes containing ethylenediaminetetraacetic acid (1.5 mg/ml), chilled immediately, and centrifuged within 8 hours of sampling. Plasma was frozen at −20° C and thawed once for assay. CRH was extracted from plasma with Sep Pak C-18 cartridges (Waters Associates, Milford, Mass.), and CRH concentrations were determined by radioimmunoassay with an antihuman CRH antibody raised in our laboratory and human CRH standard (Peninsula Laboratories, Inc., Belmont, Calif.).[2] The mean recovery of cold CRH added to charcoal-stripped plasma is 65%.

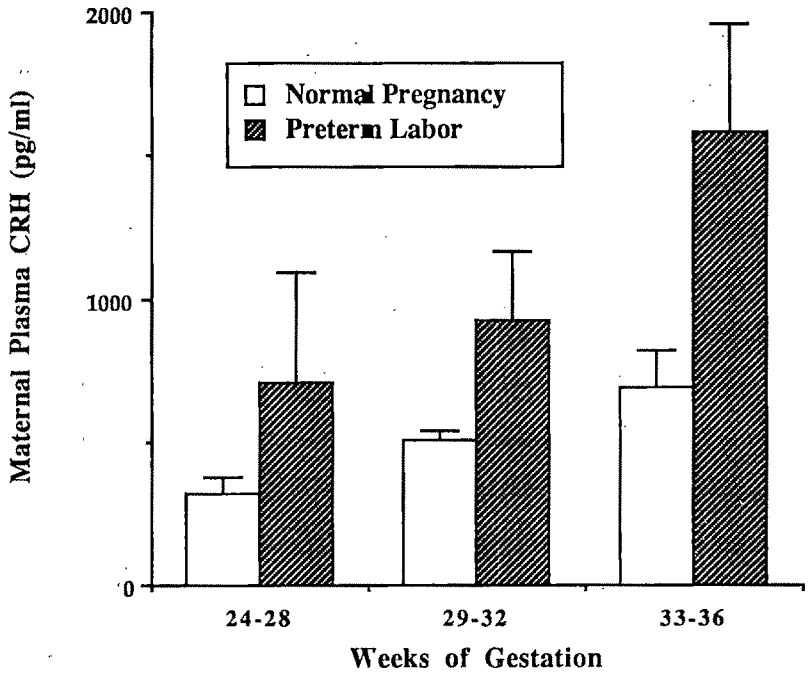

Fig. 1. Mean maternal plasma CRH levels (picograms per milliliter) in two study groups, women admitted for preterm labor and women with normal pregnancies not in labor in three gestational age groups. By two-way analysis of variance, there was significant main effect of study group on mean maternal plasma CRH levels [$F_{5.21}$ (1, 69), $p < 0.05$] with higher mean maternal plasma CRH levels in women with preterm labor.

Table I. Maternal plasma CRH mean ± SEM, in women admitted to our labor and delivery suite for treatment of preterm labor and in normal pregnancy

	Normal pregnancy		*Preterm labor*	
Gestational age (wk)	*CRH level (pg/ml)*	*No.*	*CRH level (pg/ml)*	*No.*
24-28	325 ± 47	12	772 ± 440	7
29-32	505 ± 110	9	913 ± 200	17
33-36	692 ± 125	9	1610 ± 410	15

Results

Women admitted to labor suite for treatment of preterm labor (Fig. 1). In the 39 women studied on admission to our labor suite for treatment of preterm labor, 14 were treated with tocolytic therapy and their uterine contractions were suppressed. All these women were discharged from the hospital on a regimen of oral ritodrine or terbutaline therapy. Ten subsequently were delivered at term, whereas four were lost to follow-up. For 25 women uterine contractions could not be suppressed or tocolytic therapy was contraindicated, and all of these women were delivered of preterm infants. The mean maternal plasma CRH levels were similar for women with preterm deliveries and those who were treated for preterm labor and discharged undelivered.

The mean maternal plasma CRH levels for all 39 women admitted in preterm labor and for women with normal pregnancies are shown in Fig. 1. The descriptive statistical data are also shown in Table I. Overall, the mean maternal plasma CRH concentration was higher in the preterm labor group than in normal pregnancy by two-way analysis of variance ($F = 5.21$, $p < 0.05$).

Preterm labor associated with infections (Fig. 2). Nine of the women admitted in preterm labor between 24 and 36 weeks of gestation had the clinical diagnosis of chorioamnionitis or asymptomatic bacteriuria in association with preterm labor. As shown in Fig. 2, women with preterm labor and associated infections had a mean maternal plasma CRH level similar to that of women with normal pregnancy (660 ± 104 and 490 ± 50 pg/ml, respectively). At the same gestational ages, women with preterm labor and no infections had a significantly higher mean maternal plasma CRH

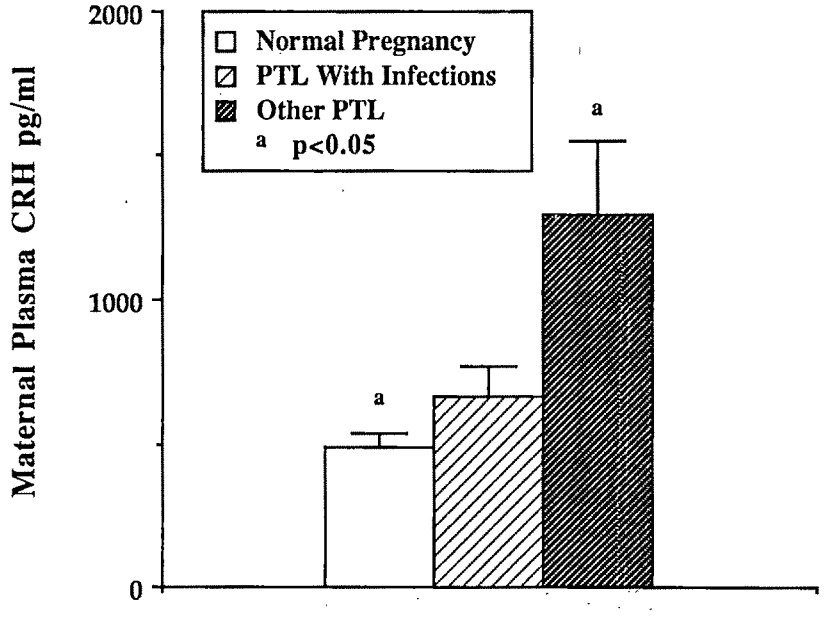

Fig. 2. Mean maternal plasma CRH levels in women at 24 to 36 weeks of gestation in preterm labor without associated infections *(Other PTL)*, in preterm labor associated with clinical infections *(PTL With Infections)*, and in normal pregnancy. By analysis of variance there was a significant effect of study group on maternal plasma CRH level [$F_{6.83}$ (2, 66), $p < 0.005$]. Mean maternal plasma CRH level for women with preterm labor and no associated infections was significantly higher than in normal pregnancy ($p < 0.05$). There was no difference in mean CRH concentration for women with infections and in normal pregnancy.

level, 1220 ± 170 pg/ml, than in normal pregnancy ($p < 0.05$).

Women followed up prospectively for risk of preterm labor (Fig. 3). We next examined the maternal plasma CRH levels in 17 women followed up in our high-risk antepartum clinic because they were at risk for preterm labor. Although nine of these women with follow-up at 29 to 36 weeks of gestation did not have preterm labor and subsequently were delivered at term, 8 of the 17 high-risk women had preterm labor. The mean maternal plasma CRH concentrations for these women and for women with normal pregnancy at 29 to 36 weeks of gestation are shown in Fig. 3. The mean maternal plasma CRH concentration was 990 ± 140 pg/ml before the onset of preterm labor. This was significantly higher than the CRH concentration in women at risk who did not have preterm labor, 560 ± 120 pg/ml, and also for women with normal pregnancy at the same gestational age, 600 ± 67 pg/ml ($p < 0.05$).

Women after treatment for preterm labor (Fig. 4). Ten women were referred to the high-risk antenatal clinic after they were treated for preterm labor. The mean maternal plasma CRH levels for these women was compared with the mean concentration for women during uncomplicated pregnancy at 29 to 36 weeks of gestation. The mean maternal CRH concentration in women after treatment for preterm labor, 1240 ± 320 pg/ml, was higher than in normal pregnancy at the same gestational age, 600 ± 67 pg/ml ($p < 0.05$).

The effect of term labor on maternal plasma CRH levels (Fig. 5). To evaluate the effect of labor itself on maternal plasma CRH levels, we compared CRH concentrations in latent and active labor in six women at term. The mean maternal plasma CRH concentration in latent labor, 1560 ± 180 pg/ml, was not significantly different from the mean concentration in active labor, 1650 ± 360 pg/ml.

Comment

In this study we report an association between early elevation of maternal plasma CRH levels and preterm labor. We studied women admitted to our labor suite for treatment of preterm labor and found significantly higher maternal plasma CRH levels in women with preterm labor than in those with normal pregnancy. However, in a subgroup of this population, women with preterm labor and associated infections, there was no elevation of maternal plasma CRH compared with levels in normal pregnancy. We also found high CRH levels before the clinical diagnosis of preterm labor in women at risk of preterm delivery. After treatment of preterm labor and suppression of uterine contractions, maternal plasma CRH levels were also higher than the levels seen in normal uncomplicated pregnancy. When we examined the effect of term labor on maternal

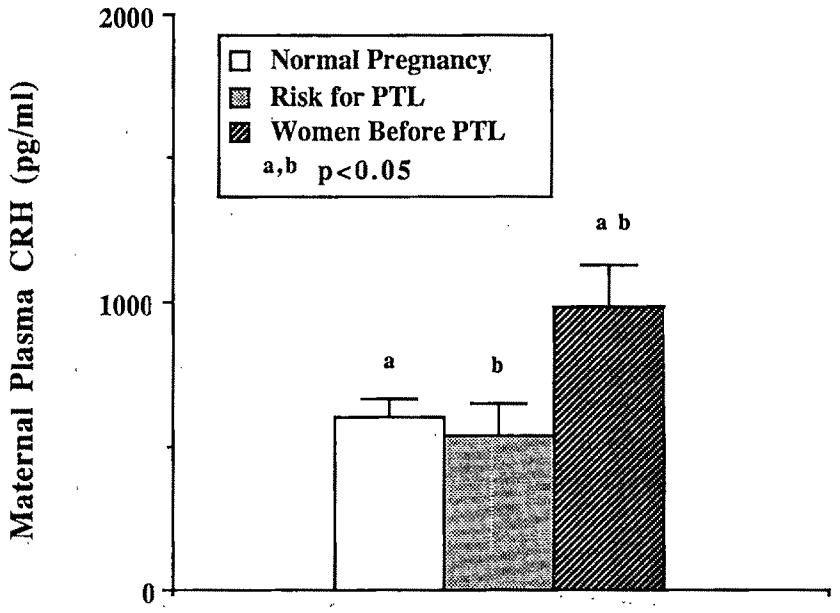

Fig. 3. Mean maternal plasma CRH levels in women monitored prospectively for risk of preterm labor and in normal pregnancy. Women at risk for preterm labor were divided into two groups: those in whom preterm labor ultimately developed *(Women Before PTL)* and women who were at risk but who did not have preterm labor *(Risk for PTL)*. By analysis of variance there was a significant effect of study group on maternal plasma CRH concentration [$F_{4,78}$ (2, 32), $p < 0.02$]. Women in whom preterm labor subsequently developed had higher mean maternal plasma CRH level than either women with normal pregnancy or women at risk who did not have preterm labor ($p < 0.05$). *PTL*, preterm labor.

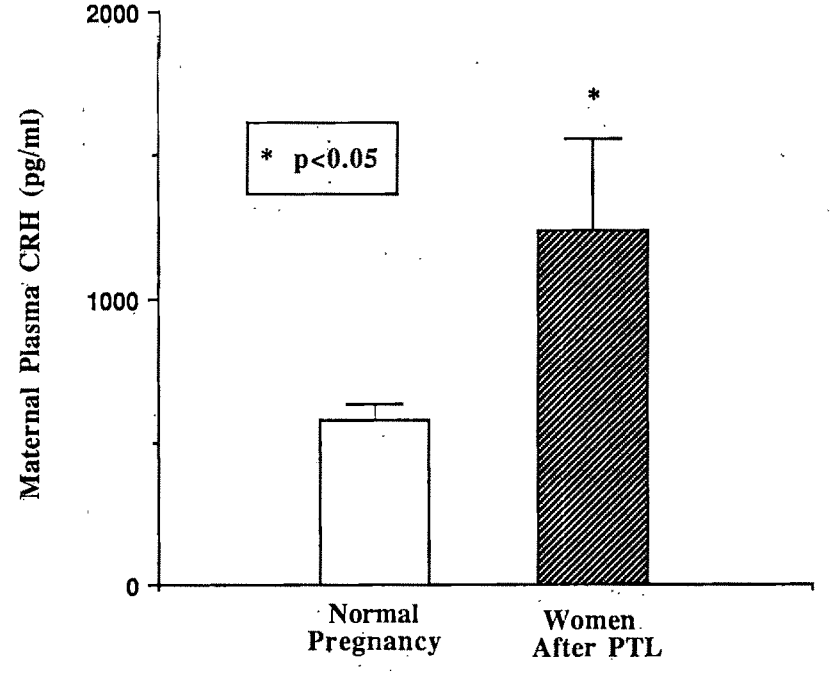

Fig. 4. Mean maternal plasma CRH levels at 29 to 36 weeks of gestation in women after treatment for preterm labor and in normal pregnancy Mean maternal CRH concentration was significantly higher for women after treatment than for women with normal pregnancies by unpaired t test ($p < 0.05$). *PTL*, preterm labor.

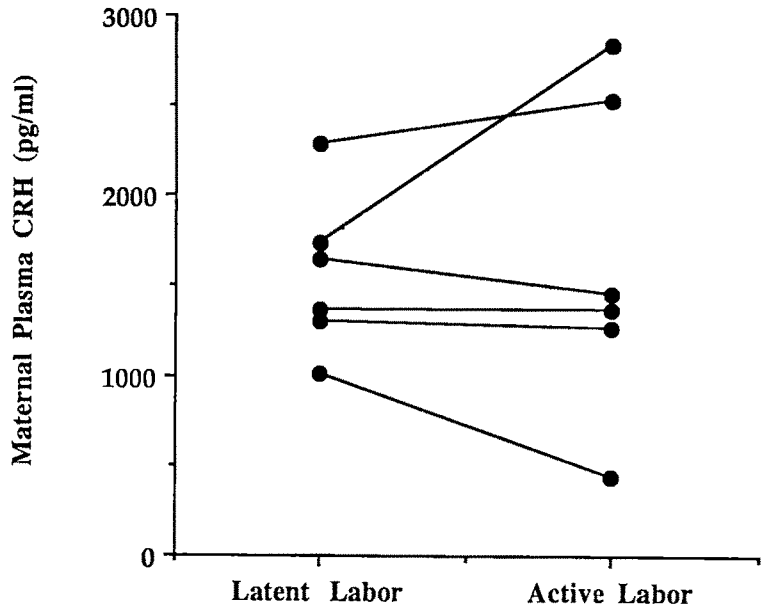

Fig. 5. Maternal plasma CRH levels in six women during both latent and active labor at 37 to 40 weeks of gestation. Mean plasma CRH levels were not different in latent and active labor.

plasma CRH levels, we found no change in mean plasma CRH levels during the acute stress of labor.

Some investigators have reported rising CRH levels during normal labor at term, suggesting that processes during labor may cause maternal plasma CRH to increase.[5, 16, 17] In one study initial blood samples were obtained as much as a week before the onset of labor.[16] Maternal plasma CRH concentrations rise exponentially in the weeks before parturition, and therefore the reported increase in CRH levels may have occurred before labor began. In another study samples in latent and active labor were obtained from different women.[5] Variation between these groups could account for the differences reported. Other investigators have found no significant increase in maternal plasma CRH levels during labor.[4, 6, 13] We found no increase in maternal CRH levels in active labor as compared with latent labor in women at term. Furthermore, maternal plasma CRH levels were elevated before labor was diagnosed in women who ultimately had preterm labor. This suggests that elevated CRH levels in patients who had preterm labor were due to mechanisms that began before the onset of labor and were not due to the process of labor itself.

Women followed up in the high-risk clinic after treatment for preterm labor had higher plasma CRH levels than found in normal pregnancy. Therefore suppression of uterine contractions at the myometrial level by tocolytic agents did not appear to cause a corresponding suppression of placental CRH secretion, although a stimulatory effect of these agents on placental CRH secretion cannot be excluded. The continued elevation of maternal plasma CRH levels without clinical evidence of uterine contractions suggests that, although activated placental CRH secretion may play a role in the initiation of parturition, it is not sufficient to cause labor and that other factors are necessary for labor to occur.

We did not use premature delivery as the end point for this study because the success of treatment for preterm labor depends on many factors unrelated to the mechanisms of labor. These include the lag time between onset of contractions and presentation to the labor suite, association with spontaneous rupture of membranes, and other perinatal complications. Further studies are needed to determine if our ability to suppress uterine contractions with tocolytic agents was related to the maternal plasma CRH concentration.

Preterm labor represents a clinical end point that most likely can be reached through several mechanisms. Studies have shown an association between preterm labor and infectious processes.[19-22] Pathways to the stimulation of uterine contractions have been suggested through bacterial endotoxins and release of cytokines in response to infectious processes, resulting in increased prostaglandin production in the amnion and decidua.[23-25] We report that maternal plasma CRH levels in women with infections and preterm labor were similar to levels found in normal pregnancy. However, CRH concentrations in women in preterm labor with-

out infections were significantly higher than normal. We thus may have identified a subset of women with preterm labor in whom secretion of placental CRH is abnormally activated. In these women the pathway to preterm labor may be through paracrine or endocrine mechanisms involving the placental-pituitary-adrenal axis.

In summary, we have shown that maternal plasma levels of placental CRH are elevated early in pregnancies complicated by preterm labor. This does not appear to be related to the process of labor itself as high levels are found before preterm labor is diagnosed clinically and we found no rise in maternal CRH levels during term labor. In a subset of women with preterm labor and associated infections, plasma CRH levels were similar to levels seen in normal pregnancy. These data suggest that early activation of the placental-pituitary-adrenal axis, as reflected by early elevations in maternal plasma CRH concentrations, may be part of a cascade of events leading to the onset of premature labor in some pregnancies.

We thank Irene Conwell, BA, for her excellent technical assistance; Rosemond Anderson, RN, and the labor and delivery staff for their assistance in collecting the samples; and Michael M. Myers, PhD, for assistance in the statistical analysis.

Discussion

Dr. Atef Moawad, Chicago, Illinois. The etiology of the initiation of term and preterm labor in women is still, to a great extent, unknown. We have witnessed over the years the debates concerning many theories—to mention some, the oxytocin theory championed by Caldeyro-Barcia, the placental progesterone theory and its local blockade to the myometrium by the late Arpad Csapo, and then there was a great excitement when Liggins identified the important role of the fetal adrenal cortex in initiating labor in the sheep. However, the effect of cortisol in the human in initiating labor, to date, remains doubtful.

We know that cortisol and cortisol-binding globulin

levels increase substantially in pregnancy,[1] and so does free and bound cortisol.[2] We know also that maternal CRH has been shown to be of placental origin. The placenta has a higher concentration of it,[3] its progressive rise in pregnancy coincides with placental maturation, and it is significantly higher in multiple pregnancies. We also know that CRH has no effect on corticotropin and cortisol secretion in women in late pregnancy.[4]

The authors are to be commended for undertaking a difficult study in which they measured CRH in pregnant women and in those who had normal labor at term. These were compared with those at risk for preterm labor. The latter group was prospectively followed up to the final outcome of either preterm labor or uncomplicated term pregnancy. They further broke down the preterm labor group into infected and uninfected cases.

Their results indicate that CRH is higher in laboring women when compared with those not in labor. They thus confirmed previous reports in which it has been shown that this hormone progressively increases in maternal plasma during pregnancy, increases further during delivery, and declines rapidly to nonpregnant levels on the first day post partum.[5-8]

The authors report the significant finding that the elevation of the maternal serum CRH precedes the onset of preterm labor (in those women at risk who eventually had progression to premature labor). To our surprise this is not the case in those patients who had an infectious process that presumably contributed to the initiation of preterm labor.

These results, again, prospectively confirm what Campbell et al.[6] showed retrospectively, that women with premature labor had plasma CRH concentrations higher than those of women with normal labor for a substantial period of time before the onset of labor.

The lack of rise of CRH in cases with infections is somewhat surprising. The authors did not elaborate on mechanisms that may be implicated. Are prostaglandins implicated as a common factor that may regulate placental CRH release? If so, why shouldn't CRH be elevated in cases of chorioamnionitis? To study this process in detail one must have more data concerning the organisms involved and the breakdown of these cases. Another question that needs to be asked is, can asymptomatic bacteriuria be considered as an infection?

One must also ask the question whether it is valid to use a single venous sample for determinations from patients with gestational ages between 24 and 36 weeks. It is expected that there would be considerable variations among individual women. Consequently, the statistics based on population or group comparison are not very convincing. It would be necessary to monitor several women longitudinally with blood samples in a serial fashion at close intervals. Some of these data have already been reported by Campbell et al.[6] One needs to know if there are diurnal variations or pulsatile secretion of the hormone.

Preterm delivery was not used as an end point. The reason given is the presence of many factors unrelated to the mechanisms of labor. Still, one would be interested in the final outcome, especially in the infected group. Although some of the data are combined appropriately in small gestational age groups (e.g., the effects of gestational age or CRH), other data are pooled from women at 29 to 36 weeks. On the basis of observed significant effects of gestational age on CRH, the appropriateness of pooling data over such an extended period of gestation is unclear.

In summary, the authors confirmed previous findings of the progressive increase in maternal CRH in pregnancy and its further rise in labor, with significantly higher levels in cases with preterm labor not associated with infections.

I commend the authors for undertaking a difficult study with many variables. I have some concerns about the pooling of the data and the lack of multiple longitudinal observations, especially in the cases that were prospectively followed up; perhaps this becomes a more compelling argument when the number of cases in some of the studied groups was small. One must consider this report preliminary and I would encourage Dr. Warren to continue the study further to validate these data.

We know from previous studies that there are low CRH levels in umbilical cord plasma, which implies that there is limited or no transfer of the placental CRH to the fetus. This means that the role of the fetus in this process is minimal. Where does this leave us as far as the fetal adrenal secretion and the mechanisms of parturition?

I wish to congratulate the authors and hope that they further elucidate some of the mechanisms that explain their results and delineate a role for this hormone.

DR. STEPHEN L. CURRY, Hartford, Connecticut. A second major problem for the practicing obstetrician is that of postdate pregnancy. I wonder if you looked at those patients who have postdates pregnancies, and do they have lower levels of CRH compared with normal patients?

DR. EBERHARD MUELLER-HEUBACH, Winston-Salem, North Carolina. With regard to chorioamnionitis, how many of the nine patients had chorioamnionitis compared with asymptomatic bacteriuria, and were there any placental pathology results available to indicate whether there was histologic chorioamnionitis? As I understand it, these were cases of clinical chorioamnionitis.

Furthermore, of the eight women who went into preterm labor out of the 17 at high risk of preterm labor, how many of those actually went on to delivery and were there any differences in CRH level among those who were delivered versus those in whom the preterm labor was successfully inhibited?

DR. CALVIN J. HOBEL, Los Angeles, California. If stress is an important part of preterm labor, i.e., the central nervous system–adrenal axis, then this could possibly mean that uteroplacental stress could increase CRH, and the question would be, what is the stimulus? Have you looked carefully at histories of these patients to sort out mental stress that would involve the maternal corticoadrenal axis or physical stress that would sort out peripheral release of neurotransmitters?

DR. JOHN LARSEN, Washington, D.C. If these were cases of asymptomatic chorioamnionitis, what method was used for sorting them out? Was it strictly cultures and maternal serologic testing or was there any invasive testing such as amniocentesis?

DR. ROBERT K. CREASY, Houston, Texas. I have two questions relative to the potential usefulness of this test. It would appear that you were giving standard errors and that these were relatively large. Could you give us some indication as to whether the ranges are going to be so wide as to potentially be useful in the clinical setting?

And second, in the patients who had elevations that were being monitored antenatally and who subsequently did have preterm labor, can you give us some idea as to the time interval between blood sampling and the development of the preterm labor process?

DR. MICHAEL R. SOULES, Seattle, Washington. From an endocrinology point of view, it has been known that measuring hypothalamic neuropeptides in peripheral serum is difficult, so I would like to know more about the CRH assay that you were using.

DR. WARREN (Closing). Let me address that last question first. We collect blood in chilled tubes, spin the blood down, and freeze the plasma. We extract the CRH with Sep Pak C-18 cartridges, after which plasma is assayed with our own antihuman CRH antibody. The intraassay coefficient of variation is 6.3%; our interassay variation is about 17%. Our recovery of synthetic human CRH is about 65%. This assay was developed by Dr. Goland in our laboratory and has been very consistent over the last 4 years or so.

To address the issue of elevation of CRH from labor itself, it is still controversial. A number of investigators have shown that CRH does increase during labor, whereas others have shown that it does not. In a preliminary study we looked at six women in latent and active labor and found no difference between levels in these women with a paired *t* test.

To address your questions on chorioamnionitis and infection, we used clinical criteria for infection and we grouped chorioamnionitis and asymptomatic bacteria together. We used a clinical diagnosis for chorioamnionitis as described by Gibbs. When we had pathologic specimens of the placentas, we used them to correlate with the clinical diagnosis. We did not have pathologic studies on all the patients. Therefore we are continuing the study now, looking at histologic diagnosis of chorioamnionitis and measuring levels of the peptide in maternal plasma and in placental extracts.

To address some of the questions with regard to the cross-sectional aspect of the study, our numbers were too small to describe the interval between sampling for CRH and the onset of preterm labor. However, we are now starting a study in which we measure levels sequentially in women at risk for preterm labor to begin to get an idea of the actual curve of the CRH in the plasma. In other words, is the curve actually shifted over so that it increases gradually to a certain point at which labor occurs or is there a sudden increase?

Our group has shown that CRH is secreted in fairly constant levels throughout the day, so there does not appear to be diurnal variation. It does not appear to be pulsatile, although we have not done the studies—and I do not believe anyone has done the studies with frequent enough measurements to determine whether it is secreted in a pulsatile nature.

As far as the question about pooled data, we obviously were very concerned that differences in gestational age would influence the level of CRH because levels go up so dramatically with gestational age, especially near term. We analyzed the gestational ages in the different groups of pooled data, and they were virtually identical with no statistical difference. So, although these are pooled data and it would be nice to have a week-by-week sample, in these small numbers we were not able to do that analysis.

CRH is present in the umbilical cord at lower levels than in the maternal plasma, and as I said, umbilical venous levels are higher than umbilical arterial levels, also suggesting the CRH is coming from the placenta. The levels are certainly within the biologically active range in the fetal plasma.

We have looked at a few patients who are postdates, but as you know from the collaborative study it is very

hard to confirm that those patients are postdates. It is something we would like to look at, but we have not gotten to it just yet.

We did break down our data to determine how many women were delivered preterm and how many were not and how many were successfully treated with tocolytic agents. There were no significant differences in CRH levels between those two groups. However, I have to say that our numbers are too small and we would like to look at that question in larger numbers to see if the actual level of CRH was related to the success or failure of tocolytic treatment.

As far as intrauterine stress and CRH, we do not know what regulates placental CRH in vivo. We know that stress certainly stimulates hypothalamic CRH, but the placenta is a completely different structure and the regulation of CRH in the placenta is unclear as yet. So I do not think that we can say that CRH is released by the placenta in acute stress. The role of chronic stress is under investigation.

As far as the potential usefulness of this as a predictor for preterm labor, the variation of levels between patients and even among single patients is quite large. In addition, women can have fairly high levels without the onset of labor, and women can have very low levels and develop labor. So I do not think we can really consider this yet as a clinical tool.

Rates and outcomes of planned pregnancy after use of Norplant capsules, Norplant II rods, or levonorgestrel-releasing or copper TCu 380Ag intrauterine contraceptive devices

Irving Sivin, MA,[a] Janet Stern, BS,[a] Soledad Diaz, MD,[b] Margarita Pavéz, RN,[b] Francisco Alvarez, MD,[c] Vivian Brache, BS.,[c] Daniel R. Mishell, Jr., MD,[d] Maria Lacarra, RN,[d] Terence McCarthy, MB, BS,[e] Pentti Holma, MD,[f] Philip Darney, MD,[g] Cynthia Klaisle, MSN,[g] Sven-Eric Olsson, MD,[h] and Viveca Odlind, MD[h]

New York, New York, Santiago, Chile, Santo Domingo, Dominican Republic, Los Angeles and San Francisco, California, Singapore, Jyväskylä, Finland, and Uppsala, Sweden

OBJECTIVES: The objectives were to measure rates of planned pregnancy and factors affecting these rates after use of very-long-acting contraceptive methods (Norplant or Norplant II implants, a levonorgestrel-releasing intrauterine contraceptive device, or the copper T (model TCu 380Ag) intrauterine contraceptive device.

STUDY DESIGN: The design was a concurrent, multicenter prospective study of 372 women who stopped contraception for planned pregnancy. Analysis was by life-table, log-rank, and standard χ^2 methods.

RESULTS: Pregnancy rates 12 and 24 months after cessation of contraceptive use were 82 and 89 per 100, respectively. Age at removal and family planning intentions at initiation of contraception were both significantly correlated with pregnancy rates ($p < 0.05$), but former contraceptive regimen and duration of contraceptive use were not. Pregnancy outcomes did not deviate from normal limits and did not differ by contraceptive formerly used.

CONCLUSION: Contraceptive implants releasing 30 μg/day of levonorgestrel or intrauterine contraceptive devices releasing 20 μg/day of levonorgestrel or having copper surface areas of 380 mm² are associated with normal fertility after use for women seeking pregnancy at termination. Durations of use do not affect pregnancy rates. (Am J Obstet Gynecol 1992;166:1208-13.)

Key words: Pregnancy after contraception, implant reversibility, post-IUD fertility

Preservation of reproductive potential is an essential feature of contraceptive methods. Studies have shown an initial delay of fertility after combined oral contraceptive use in comparison with the experience of women who stopped use of intrauterine contraceptive devices (IUDs) or diaphragms.[1] The progestin-only injectables, depot medroxyprogesterone acetate and norethindrone acetate, also have been associated with delays of pregnancy subsequent to use.[2-4] Proportions pregnant within 12 or 24 months, however, indicate normal fertility after cessation of use of these steroidal contraceptives. In contrast, case-control studies have suggested an association between prior use of IUDs and infertility at 1 year, mediated by pelvic inflammatory disease and multiple sex partners.[5, 6] Because preservation of reproductive potential is a critical issue in contraception, as new contraceptives emerge and progress toward general distribution, they require evaluation of the pace and completeness of achievement of pregnancy and childbirth after cessation of method use. The need for evaluation is particularly compelling with very-long-acting medicated contraceptive methods. Prolonged medication may affect normal reproductive

function even after contraception has ceased and may therefore impose extended delays in conception. We report pregnancy rates and outcomes subsequent to cessation of use of four relatively new, long-acting contraceptives, all of which first received regulatory approval between 1983 and 1990 for periods of 3 to 5 years of continuous use.

Material and methods

Contraceptive methods. Two medicated IUDs, a device releasing 20 μg/day of levonorgestrel and a copper T, model TCu 380Ag, were in randomized trials from 1981 through 1990 in seven centers.[7-9] Another set of seven clinics compared two subdermal implant systems, Norplant capsules and Norplant II rods, in trials from 1982 through 1990.[10-12] Clinics participating in both trials contributed 76% of studied removals for planned pregnancy.

The Norplant capsule system (Leiras Pharmaceuticals, Turku, Finland) releases a rated 30 μg/day of levonorgestrel for 5 years. After removal of capsules, residual levonorgestrel is rapidly metabolized. With an initial half-life of 18 hours, the drug is undetectable 1 week after removal.[13]

The Norplant II system (Leiras) is a set of two 4.4 cm rods that release 30 μg/day of levonorgestrel from a cured homogeneous mixture of the drug and a polydimethylsiloxane elastomer covered by thin-walled silicone rubber tubing. Once these rods are removed, levonorgestrel levels decrease as described for capsule implants. Rod implants have been approved for 3 years of continuous use in Finland. Subjects assigned to particular Norplant II manufacturing lots were, however, permitted continuous use for 5 years.

The levonorgestrel-releasing IUD (Leiras) releases drug at a rated 20 μg/day from a cured homogeneous rod of levonorgestrel and polydimethylsiloxane elastomer. Two variants with drug loads of 46 and 60 mg were studied for 5 and 7 years, respectively. The IUD, here designated as the LNg 20, has been approved for 5 years of use in Finland.

The copper T IUD, model TCu 380Ag (Outokumpu Oy, Pori, Finland), has a copper surface of approximately 380 mm^2. A silver core wire differentiates this from the similar device marketed in the United States. Approved for 5 years of use in Finland, this IUD was studied for 8 years of continuous use.

All four contraceptive systems were developed by the Population Council's International Committee for Contraception Research or by the Population Council's licensee.

Conduct of trial and follow-up after removal. For admission to either trial, women had to be healthy, to be regularly exposed to the risk of pregnancy, and to have no contraindications to combined oral contraceptives; in the IUD trial they had to be without uterine anomalies contraindicating IUD use. Previous pregnancy was required. Women with a history of pelvic inflammatory disease since the last pregnancy were excluded. At admission, women in the IUD trial were 18 to 38 years old; in the implant study they were 18 to 40 years old.

Subjects gave informed consent and were monitored 1, 3, and 6 months after admission and semiannually thereafter. Except in the case of IUD expulsion, stopping required a clinic visit for extraction of the IUD or implant. Three-year continuation rates were >50 per 100 for each regimen. Large percentages of subjects using Norplant, Norplant II, or the levonorgestrel-releasing IUD therefore reached the putative end of the contraceptive's effective period. The majority of these women adopted contraception again immediately after removal, as had the majority of subjects who discontinued use because of menstrual or other medical problems.

Women with removals for planned pregnancy were asked to maintain contact until pregnancy and its subsequent outcome. Data in this report stem from clinics that determined the subsequent pregnancy status of at least 75% of subjects who ceased use by October 1990. As of July 1991, 91.9% of these women had been contacted after removal for planned pregnancy.

Rates of planned pregnancy were computed by actuarial life-table methods, which calculate the exposure interval from the date of removal of the contraceptive device to the date of pregnancy, or report of change of mind, or separation from husband or partner, or use of another contraceptive. After removal, between 8% (LNg 20 IUD) and 19% (Norplant) of women changed their minds and/or were no longer exposed to the risk of pregnancy. These women are included during the exposure interval in the analysis of pregnancy rates. Eight percent of women were not seen after removal and are not included in the life tables. Log-rank χ^2 methods tested statistical significance among life-table pregnancy rates. Contingency table χ^2 methods tested for statistically significant differences among pregnancy outcomes and subject characteristics.

Characteristics of subjects. At seven clinics 2748 subjects had enrolled in contraceptive trials. By October 1990, 372 of these requested removal for a planned pregnancy. Smaller proportions of implant subjects (10% to 12%) than of IUD subjects (17% to 20%) sought such a removal (Table I). Median ages at admission were 26 years for all IUD subjects and 27 years for the implant subjects. Average age at admission of the women who later sought planned pregnancy was 1 to 2 years below the overall average. Mean age at removal for planned pregnancy was 27.8 years, with significant variation by contraceptive method (Table I) ($p < 0.05$).

Women who had used Norplant II implants were youngest at removal, 26.7 years, while copper T users were oldest, 28.6 years. Age at Norplant capsule removal was 1.5 years greater than age at removal of Norplant II ($p < 0.05$) (Table I).

Mean parity at removal was 1.75, with a range from 1.70 to 1.80 children by contraceptive method (Table I). Twenty-four percent of women requesting removal for planned pregnancy had stated at admission they did not want additional children.

Women planning pregnancy used the copper T device an average of 38.9 or 8.7 months longer than their peers used the LNg 20 IUD ($p < 0.01$) (Table I). Norplant capsules were used a mean of 4.5 months longer than were rod implants ($p < 0.05$).

Results

For the entire group of women who planned pregnancy, the 12-month life-table rate of pregnancy was 82 per 100. This rate ranged by device from 77 to 84 per 100 (Table II). Two years after removal, the pregnancy rate was 89 per 100, varying by former contraceptive regimen from 87 to 92 per 100 (Table III). Neither 1- nor 2-year cumulative conception rates differed significantly by method formerly used.

Eighty-five per 100 women seeking pregnancy before age 30 achieved it in the first year, a rate not significantly affected by method formerly used (Table II). When the quest for pregnancy began at age ≥30, the 1-year pregnancy rate was about 10 per 100 lower than that of women aged <30 ($p = 0.08$). Higher pregnancy rates among younger women were manifest with each of the four methods (Table II). Two years after ceasing contraception, 93 per 100 of the younger women were pregnant, a rate 13 per 100 higher than that of women ≥30 years old ($p = 0.03$, Table III).

Univariate analysis by duration of contraception indicated no significant variation in pregnancy rates ($p = 0.20$). Among women who had used contraception ≥3 years, the 12-month pregnancy rate was 84 per 100 and was essentially uniform by method, 82 to 85 per 100 (Table II). Women who used contraception <3 years had a similar 12-month pregnancy rate, 81 per 100. Two years after removal, the pregnancy rate was 89 per 100 for each duration-of-use group.

Parity had little effect on conception rates. At 1 year the pregnancy rate of women with fewer than two children was 83 per 100, comparable to the 81 per 100 among women with two or more children (Table II). Two years after device removal, pregnancy rates by parity group were 89 to 90 per 100.

contraceptive trial was significantly related to posttrial pregnancy rates. Women who had expressed a desire to have more children at study entry, i.e., contraceptive spacers, had pregnancy rates of 85 per 100 at 1 year and 92 per 100 at 2 years. These were substantially above the rates of 70 and 81 per 100 at 1 and 2 years, respectively, for family limiters, women who had stated at admission they did not want additional children ($p = 0.03$).

We examined effects on pregnancy rates of the dichotomous categories of age (<30 or ≥30 years), duration of contraceptive use (<37 or ≥37 months), and family planning intention at admission (spacer or limiter) by holding the other variables constant. Younger age (<30 years) was associated with higher pregnancy rates than was older age in all four duration–family planning intention groupings, confirming the significant finding at 2 years in the univariate analysis (Table III). Family planning spacers in all age–duration-of-use comparisons had higher pregnancy rates 1 and 2 years after removal than did women who entered the trials as limiters of family size. Women with longer durations of contraceptive use had higher pregnancy rates than did shorter-term users in all four age–family planning intention groups. The magnitudes of the effect of age and duration were greater among women who were initial limiters than among initial spacers.

The joint effects of family planning intention, age, and duration of use were strong. Women <30 years old at removal of the contraceptive who had used contraception to space children and who had used the contraceptive ≥37 months had a 1-year pregnancy rate of 93 per 100. In contrast, women ≥30 years old who used contraception to limit family size and used the contraceptive method <37 months had a pregnancy rate of 58 per 100 ($p < 0.02$).

$p > 0.05$.

Women who reported a history of pelvic inflammatory disease followed by a pregnancy and then entry into the randomized IUD trial had the same rate of conception as did women with no reported history of PID (Table II).

Although conception rates 1 and 2 years after removal were within normal limits, pregnancy rates in the first 3 months after removal differed considerably among methods ($p < 0.01$). Fifty-eight percent of women who had discontinued Norplant II rods became pregnant within 3 months, in contrast to 34% of former users of levonorgestrel-releasing IUDs. Forty-three percent and 37%, respectively, of copper T IUD and Norplant capsule users were pregnant within 3 months.

During use of the levonorgestrel IUD, substantial proportions of women experienced no menstrual events in any given calendar month.[7, 8] When the levonorgestrel IUD was removed for planned pregnancy, 25% of women had not menstruated in the preceding 90 days. The first-month pregnancy rate was 5 per 100 for this group. First-month pregnancy rates for other users of this IUD also were below the expected range of 16 to 33 per 100. Nevertheless, by the end of the first year, cumulative conception rates by duration of amenorrhea preceding removal were in the normal range, 80 to 92 per 100 among former users of the levonorgestrel IUD (Table II).

Pregnancy outcome. By July 1991 the outcomes of 92.1% of the pregnancies had been established. Of these, 88% had terminated with a live birth. Two infants (0.9%) had birth weights <2500 gm (Table IV). One tubal pregnancy occurred in a former Norplant II rod implant user. Female infants constituted 50.5% of all infants born; sex ratios did not vary significantly by device ($0.25 < p < 0.50$). Pregnancy outcomes did not differ by contraceptive previously used ($0.25 < p < 0.50$, Table IV). Apart from the two premature births all children were reported as healthy or normal.

Comment

Women who had stopped use of any of four new contraceptives to become pregnant conceived at rates (77 to 84 per 100) within the sampling error of 85 per 100 for the 1-year rate demographers regard as typical.[14] Two years after devices were removed, pregnancy rates ranged from 87 to 92 per 100 by method formerly used. At neither 1 nor 2 years did pregnancy rates differ significantly by former method.

Fecundability, the probability of conception in the first month, was depressed among women who used the levonorgestrel IUD, especially among those who experienced no menstrual bleeding in the 90 days preceding device removal. Nevertheless, women who had used this IUD had the same normal cumulative pregnancy rates at 1 and 2 years as did women whose contraception was with the other study methods. Users of the two types of levonorgestrel-releasing implant experienced normal fecundability and pregnancy rates. The Norplant and Norplant II systems thus differ from progestin-only injectables in which women must wait 1 to 3 months or more for the injected drug to disappear before effectively stopping contraception and for which an initial delay of conception has been recorded.[2-4]

Pregnancy rates were significantly associated with age at removal and family planning intentions at study admission. Among women <30 years old, the 2-year probability of pregnancy, 93 per 100, was 13 per 100 higher than that of women ≥30 years old. Similar observations concerning age in previous IUD studies in an implant study and in the general population have been reported.[15-21]

Duration of use, dichotomized at 3 years, had no significant impact on cumulative pregnancy rates for any of the methods. With age and prior family planning intention held constant, longer duration of use (≥37 months) seemed to be associated with moderately increased pregnancy rates but not significantly so. Diaz et al.[19] suggest duration has no effect on planned pregnancy after 5 years of Norplant use. Absence of duration effects on recovery of fertility has been suggested by several authors for former IUD users.[15-19, 22]

Initial family planning intention to have another child was associated with increased pregnancy rates, when duration of use and age were held constant. The

data suggest that women whose family planning intentions had changed may have remained ambivalent about the planned pregnancy and this ambivalence may have affected the frequency of their exposure to unprotected intercourse.

The current study also suggests that women who experienced both pelvic inflammatory disease and a subsequent pregnancy before IUD use have no greater difficulty conceiving than do other women who had used IUDs or Norplant capsules or rods.

The proportions of births, spontaneous abortions, and ectopic pregnancies in this study agree with those found in large studies of former users of contraception.[23, 24] Contemporary estimates of ectopic pregnancy rates have been >1% of recognized pregnancies for several years in the United States and northern Europe, well above the 0.4% observed in this study.

The findings of a significant effect of initial family planning intention on subsequent pregnancy rates suggests potential difficulties or pitfalls in studies that ascertain recovery of fertility among women who stop using contraception because of side effects. Among such women pregnancy rates may be affected by ambivalence with respect to pregnancy.

Women in this study represent a self-selected group who stopped contraception to become pregnant. Thus the generality of these findings may be limited. Case-control studies of infertility and contraception are affected by similar limitations, derived from the self-selection of subjects. In studies of tubal infertility after IUD use cases have been women who sought medical evaluation of infertility. Cases have differed significantly from controls in income[5] and geographic location,[6] as well as in smoking and sexual behavior. Markedly incomplete coverage of cases and controls has also characterized these case-control studies of relative risks of infertility after contraception.

In this study of women desiring pregnancy after contraception, the 1-year life-table rate of conception was 82 per 100. The complement of that rate, 18 per 100, does not materially differ from the 17 per 100 rate of secondary subfertility estimated by Greenhall and Vessey.[25] We conclude that neither the recovery of fertility nor pregnancy outcomes are adversely affected by any of these four new methods of contraception.

Progression of diabetic retinopathy in pregnancy: Association with hypertension in pregnancy

Barak Rosenn, MD,[a] Menachem Miodovnik, MD,[a] George Kranias, MD,[b] Jane Khoury, MS,[c] C. Andrew Combs, MD, PhD,[a] Francis Mimouni, MD,[c] Tariq A. Siddiqi, MD,[a] and Matthew J. Lipman, MD[b]

Cincinnati, Ohio

OBJECTIVE: To test the hypothesis that women with insulin-dependent diabetes and chronic or pregnancy-induced hypertensive disorders are at increased risk for developing retinopathic complications during pregnancy.

STUDY DESIGN: One hundred fifty-four women with insulin-dependent diabetes were prospectively followed in an intensive program of diabetes in pregnancy. Ophthalmologic evaluations were obtained through pregnancy and at 6 to 12 weeks post partum, and findings were graded by a standard scale. Association of retinopathic progression with risk factors was tested with χ^2 and multiple logistic regression analysis.

RESULTS: Fifty-one women had progression of retinopathy during pregnancy; postpartum regression was observed in 13 women. Changes in glycemic control early in pregnancy, chronic hypertension, and pregnancy-induced hypertension were significantly associated with progression of retinopathy.

CONCLUSION: Women with insulin-dependent diabetes who have hypertensive disorders in pregnancy are at increased risk for progression of retinopathy. (Am J Obstet Gynecol 1992;166:1214-8.)

Key words: Diabetes, retinopathy, pregnancy, pregnancy-induced hypertension

The effect of pregnancy on the natural course of diabetic retinopathy is a matter of controversy.[1] Although some patients with insulin-dependent diabetes experience rapid worsening of retinopathy during pregnancy, others do not. Moreover, retinal changes observed during pregnancy frequently improve post partum.[1]

Systemic hypertension is also associated with retinal changes, and advanced diabetic retinopathy may be associated with lesions similar to those caused by atherosclerosis and arterial hypertension. We therefore hypothesized that women with insulin-dependent diabetes with chronic or pregnancy-induced hypertensive disorders are at increased risk of developing retinopathic complications during pregnancy.

Material and methods

From 1978, women with type I insulin-dependent diabetes with a history of diabetic ketoacidosis have been enrolled in our continuing program of diabetes in pregnancy at the University of Cincinnati.

Complete medical and obstetric histories were obtained on enrollment. Pregnancy dating was based on menstrual dates and confirmed by physical and ultrasonographic examination. Subjects were examined every 1 to 2 weeks, at which time blood glucose level, body weight, blood pressure, results of urinalysis, and insulin dose were recorded. Glycemic control was maintained with split-mixed-dose regimens of short- and intermediate-acting insulin preparations, along with dietary regulation. The goals of glycemic control were a fasting blood glucose concentration of <100 mg/dl and a 90-minute postprandial glucose concentration <140 mg/dl. Patients were hospitalized when necessary to maintain these goals. In addition, after 1982 patients routinely performed and recorded self-monitoring of blood glucose with reflectance meters. Maternal blood glycohemoglobin A_1 concentrations were measured at entry and every 4 weeks thereafter by Isolab column chromatography (interassay coefficient of variation 7.2%, normal range 5.5% to 8.5%).[2]

Patients underwent ophthalmologic evaluations by one of two ophthalmologists once each trimester and 6 to 12 weeks post partum. Direct and indirect ophthalmoscopy, documented with color photography, was performed at the time of evaluation. Retinopathy was

Table I. Classification of diabetic retinopathy

Grade	*Criteria*
0	Normal fundi
Background retinopathy	
1	Mild background retinopathy: microaneurysms only (one or more)
2	Moderate background retinopathy: microaneurysms, hemorrhages, and soft and hard exudates
3	Extensive background retinopathy: microaneurysms, soft or hard exudates, intraretinal microvascular abnormalities, and venous bleeding
Proliferative retinopathy	
4	Mild proliferative retinopathy: optic disc neovascularization less than standard picture 10c of Diabetic Retinopathy Study[3] or retinal neovascularization less than standard picture 7
5	Moderate proliferative retinopathy: optic disc or retinal neovascularization equal to or more than standard pictures 10c and 7
6	Extensive proliferative retinopathy: optic disc or retinal neovascularization with fibrous proliferation, retinal elevation, or preretinal or vitreous hemorrhage

graded according to funduscopic findings as shown in Table I. The following definitions were used in this study: *progression of retinopathy,* development of retinopathy de novo or upgrading of retinopathy from first or second trimester to later trimesters or post partum or changes in women with grade 6 retinopathy requiring additional photocoagulation; *pregnancy-induced hypertension,* more than one occurrence, 24 hours apart, after 20 weeks' gestation of a mean arterial pressure ≥105 mm Hg or an increase ≥20 mm Hg from baseline; *chronic hypertension,* presence of mean arterial pressure ≥105 mm Hg before 20 weeks' gestation or chronic hypertension diagnosed before pregnancy with or without history of use of antihypertensive medications before pregnancy; *chronic hypertension with superimposed pregnancy-induced hypertension,* an increase of ≥20 mm Hg in mean arterial pressure from baseline after the first 20 weeks of gestation in a patient previously defined as a chronic hypertensive. The current analysis includes all women who had at least two ophthalmologic evaluations during pregnancy, including one in the first or second trimester and one in the third trimester or post partum. In the absence of a third-trimester evaluation (because of either early delivery or noncompliance), a postpartum evaluation showing progression of retinopathy was considered indicative of progression occurring during late pregnancy. Changes in a patient were defined whether present in one or both eyes.

Data were analyzed with SAS (Statistical Analysis Systems, Cary, N.C.). χ^2 was used for categorical variables and the Student t test for continuous variables. The logistic regression model included variables found to be significant on univariate analysis. A p value <0.05 was considered significant.

Results

One hundred fifty-four women with insulin-dependent diabetes had at least two ophthalmologic evaluations during pregnancy (49 had four evaluations, 91 had three, and 14 had two); 51 women (33%) had progression of retinopathy during pregnancy. Retinopathy progressed in 37 women by one grade, in nine by two grades, and in five by three grades or more. Spontaneous improvement from grade 2 in the first trimester to grade 1 in the second was observed in two women. Factors associated with progression of retinopathy during pregnancy are presented in Table II. Women with advanced White class were more likely to have progression than women of White class B or C ($p = 0.01$). Progression of retinopathy was significantly associated with duration of diabetes ($p = 0.04$) and with first-trimester retinal grade ($p = 0.01$). First-trimester mean glycohemoglobin and the magnitude of decrease in mean glycohemoglobin from first to second trimester were also significantly positively associated with retinal changes ($p = 0.01$).

Twenty-two women had development of pregnancy-induced hypertension and three of the 18 women with chronic hypertension had development of superimposed pregnancy-induced hypertension. The associations of retinal changes with hypertensive disorders are outlined in Table III. Women with pregnancy-induced hypertension were significantly more likely than normotensive women to have progression of retinopathy. Women with chronic hypertension (with or without superimposed pregnancy-induced hypertension) were at high risk for progression of retinopathy during pregnancy.

Seven women (three without pregnancy-induced hypertension, two with pregnancy-induced hypertension, two with superimposed pregnancy-induced hypertension) with preexisting background retinopathy had proliferative changes during the course of pregnancy that necessitated photocoagulation therapy. Thirteen of the 51 women who had retinopathic progression during pregnancy experienced postpartum regression of the changes; the distribution of these 13 women was

Table II. Factors associated with progression of retinopathy during pregnancy

	No progression (n = 103)	*Progression (n = 51)*	*Significance (p)*

Table III. Progression of diabetic retinopathy in pregnancy: Association with hypertensive disorders

	No.	*No progression (n = 103)*	*Progression (n = 51)*	*Significance (p)*
No hypertensive disorder	114	85 (75%)	29 (25%)	
				0.02
Pregnancy-induced hypertension	22	11 (50%)	11 (50%)	
Chronic hypertension (with or without superimposed pregnancy-induced hypertension)	18	7 (39%)	11 (61%)	0.001
All hypertension (pregnancy-induced, chronic, superimposed pregnancy-induced)	40	18 (45%)	22 (55%)	0.0001

as follows: 7 of the 29 normotensive (24%), 3 of the 11 with pregnancy-induced hypertension (27%), and 3 of the 11 with chronic hypertension (27%). None of the women who had proliferative changes during pregnancy had spontaneous regression of the lesions.

Multiple logistic regression analysis was performed to determine which of the univariately significant variables were independently associated with progression of retinopathy. Results indicated that the magnitude of decrease in glycohemoglobin from first to second trimester, pregnancy-induced hypertension, and chronic hypertension were all independently associated with retinopathic progression ($p = 0.004$, $p = 0.01$, $p = 0.02$, respectively). The correlation between first-trimester glycohemoglobin and glycohemoglobin decrease from first to second trimester was 0.71 ($p = 0.0001$); higher first-trimester glycohemoglobin concentrations were associated with greater decreases in glycohemoglobin from first to second trimester. The interaction between these two variables with regard to progression of retinopathy was nonsignificant ($p = 0.7$).

Odds ratios for retinopathic progression were calculated with regard to chronic hypertension, pregnancy-induced hypertension, and a decrease of >2% in glycohemoglobin in women with first-trimester values >8.5%. Odds ratios (with 95% confidence limits) were 2.1 (1.7 to 3.6), 1.8 (1.1 to 3.1), and 1.4 (0.9 to 2.2), respectively.

Comment

Several reports indicate that chronic hypertension may be associated with retinopathy in diabetic patients.[4, 5] However, the association of pregnancy-induced hypertension in an otherwise normotensive pregnant women with insulin-dependent diabetes and progression of retinopathy has not been previously elucidated. Although some authors have found no such association,[6, 7] others have noted a coincidence of pregnancy-induced hypertension and proliferative retinopathy.[8, 9] Most reports do not include an analysis of such possible associations. From our data we conclude that the presence of any hypertensive disorder of pregnancy is associated with progression of diabetic retinopathy.

This conclusion holds true both for previously normotensive women who have development of pregnancy-induced hypertension and, in general, for women with any kind of hypertensive disorder in pregnancy.

There is evidence to suggest that the normal regulatory mechanisms controlling microvasculatory flow are impaired in diabetes[10, 11] and that this impairment parallels the progression of vascular disease. Although mechanisms underlying the association of diabetic retinopathy with hypertension are unclear, it is conceivable that alterations in blood pressure constitute an additional detrimental stress on an already impaired autoregulatory mechanism of blood flow control. Indeed, even intermittent alterations in blood pressure may produce significant blood flow changes in retina vessels[12] and aggravate retinal microangiopathy.[13] Thus the transient hypertension of pregnancy may have a detrimental effect on the already vulnerable diabetic retina. In addition, the mechanisms underlying changes in systemic blood flow and pressure in pregnancy-induced hypertension might also exert a direct effect on retinal microvasculature.

Our findings support previous observations that in pregnant and nonpregnant women with insulin-dependent diabetes the duration of diabetes and the severity of existing retinopathy are major determinants of the progression of retinal disease.[12] Several authors have reported an association between worsening retinopathy and the induction of intensive insulin therapy in nonpregnant subjects with insulin-dependent diabetes.[14-16] Phelps et al.[17] found such an association in women with insulin-dependent diabetes enrolled in an intensive treatment program during pregnancy. In our study a strong association was found between the occurrence of retinal changes and the change in glycohemoglobin from first to second trimester, reflecting the magnitude of change in glycemic control instituted early in pregnancy. However, we also found an association between retinal change and mean first-trimester glycohemoglobin, reflecting glycemic control during the initial stage of pregnancy. The women with higher first-trimester glycohemoglobin values are also those in whom the greatest reduction in glycohemoglobin is to be expected once they enter an intensive program of diabetes in pregnancy. Indeed, the correlation between these two variables was found to be highly significant, whereas the interaction between them was nonsignificant, which would imply that they have no independently additive effect on progression of retinopathy. Thus progression of retinopathy during pregnancy may be associated with either of the following factors: institution of rapid glycemic control in the first trimester or, alternatively, poor glycemic control early in pregnancy. We believe the latter hypothesis to be true and support the opinion of Phelps et al.[17] advocating the pursuit of good glycemic control in diabetic women as early in pregnancy as possible, because the association of poor glycemic control with adverse pregnancy outcome is now widely recognized.[18] Moreover, it has been shown that the accelerated progression of diabetic retinopathy observed in patients receiving intensive insulin therapy is not sustained over time and that these patients tend to have less overall deterioration over the course of 2 years.[19] Preconceptional institution of intensive insulin therapy has been associated with improved pregnancy outcome[20-22]; it remains to be seen whether patients may benefit from such an approach with regard to progression of retinopathy and whether preconceptional normalization of glycohemoglobin is associated with a lower risk for progression of retinopathy during pregnancy.

It is clear that at least in some women with insulin-dependent diabetes who experience progression of background retinopathy during pregnancy postpartum regression of these changes may be expected.[7, 23] How long it may take for such regression to be evident is unclear, and we cannot exclude the possibility that some of the women in our study experienced improvement after the 6- to 12 week-postpartum examination. Because pregnancy-induced hypertension is a transient phenomenon related to pregnancy, it might be expected that the rate of postpartum regression of retinopathic changes would be higher in women with insulin-dependent diabetes who have pregnancy-induced hypertension than in chronically hypertensive or normotensive women. However, we found that the rate of postpartum retinopathic regression was similar among women with or without pregnancy-induced hypertension. This observation supports the contention that even transitory changes in blood pressure may exert permanent retinopathic effects.

Prenatal ultrasonographic findings associated with wide clefting of the upper two thirds of the fetal sternum

Paula R. Mahone, MD, David M. Sherer, MD, Carl D'Angio, MD, and James R. Woods, Jr., MD

Rochester, New York

Complete or partial absence or clefting of the fetal sternum is uncommon. A teenage primiparous patient at 34 weeks' gestation with severe preeclampsia was delivered of an infant with wide clefting of the upper two thirds of the sternum. The infant had no respiratory or cardiac symptoms. There were no other congenital abnormalities. Corrective neonatal surgery was performed at 1 month of age. Retrospective analysis of the ultrasonographic examination performed at 34 weeks revealed evidence of this fetal sternal defect. (AM J OBSTET GYNECOL 1992;166:1219-21.)

Key words: Partial cleft of fetal sternum, ultrasonography

Partial absence of the fetal sternum is a rare occurrence. Three instances of complete absence of the sternum have been reported since 1979.[1] More commonly, clefting, perforation, or indentation of the sternum has been observed.

We present a case of the prenatal ultrasonographic findings associated with wide clefting of the superior two thirds of the fetal sternum.

Case report

A 14-year-old, gravida 2, para 0, Hispanic female patient presented for prenatal care at 30 weeks' gestation. Ultrasonography at that time revealed a singleton fetus with what appeared as normal fetal anatomy and growth parameters that were appropriate for gestational age.

She was hospitalized at 34 weeks 1 day of gestation with preeclampsia. She was asymptomatic. Blood pressure ranged between 140 and 170/100 and 110 mm Hg and she had proteinuria (2+). Physical examination was remarkable for a fundal height of 27 cm, 3+ deep tendon reflexes, and trace pedal edema. Fetal heart rate monitoring revealed a reactive nonstress test.

Intravenous magnesium sulfate was continued at a rate of 2 gm/hr after an intravenous loading dose of 4 gm. Subsequent blood pressure measurements taken in the left lateral recumbent position were between 130 and 140/80 and 100 mm Hg. Ultrasonography on admission revealed a vertex-presenting infant with reduced amniotic fluid volume. The estimated fetal weight was 1895 gm, which is the 20th percentile for 34 weeks' gestation.

Laboratory values of significance included a uric acid level of 7.1 mg/dl. (The results of a 24-hour urine collection were available after delivery and revealed >13 mg of protein and a creatinine clearance of 132 ml/min.) On the third hospital day, fetal monitoring revealed a reactive nonstress test with decreased beat-to-beat variability. Blood pressure was 150/100 mm Hg. A subsequent fetal heart rate tracing showed fetal distress with a repetitive late deceleration pattern. The patient underwent a primary low-transverse cesarean section for severe preeclampsia and fetal distress.

A 1625 gm female infant with Apgar scores of 4 and 9 at 1 and 5 minutes, respectively, with thick meconium, was delivered. There was no meconium below the vocal cords. Physical examination of the infant in the delivery room revealed complete absence of the manubrium sterni and wide clefting of the upper two thirds of the body of the sternum (Fig. 1, *A*). The sternal abnormality was U-shaped with the apex at the level of the fifth rib and measured 4 cm in width. The lower segment of the sternum, as well as the xiphoid, was intact and together they measured 2 cm in length. The medial aspects of the laterally displaced clavicles and the anterior aspects of the ribs were palpable at the margins of the defect. Cardiac activity was easily observed through the intact skin. There were no other abnormal findings.

The infant did not manifest any respiratory symptoms. An electrocardiogram and an echocardiogram were normal. Chest x-ray film showed lateral displacement of the clavicles with normal configuration of the ossified portions of the 12 ribs (Fig. 1, *B*). A computerized tomographic scan of the thorax revealed absence of the upper two thirds of the sternum. Retrospective analysis of the ultrasonographic examination per-

formed at 34 weeks suggested evidence of the fetal sternal defect (Fig. 2). Because of potential injury to the unprotected neonatal heart, corrective surgery of the anterior chest wall was performed on the infant at 4 weeks of age. The diagnosis of an absent manubrium sterni and wide superior sternal clefting was confirmed at operation, and the infant's postoperative course was unremarkable.

Comment

The sternum originates from the lateral plate mesoderm that will also form the pectoralis muscle. The earliest indication of the sternum is a pair of mesenchymal bands that can be identified in the human embryo at 6 weeks.[1] These bands lie ventrolaterally in the body wall and initially have no connection with the ribs or with each other. After attachment of the ribs to the sternal bars, the paired bands unite progressively in a craniocaudal direction. At 9 weeks the union of the cartilaginous bands is complete. The cranial end of the developing sternum incorporates two separate suprasternal cartilages with which the clavicles articulate. These cartilages join the manubrium of the sternum and subsequently lose their identity. The ossification centers of the sternum normally appear later in the midline, at approximately 20 to 24 weeks' gestation.

Congenital absence of the sternum is usually seen in association with other fetal anomalies such as ectopia cordis or pentalogy of Cantrell (midline supraumbilical abdominal defect, defect of the lower sternum, defi-

ciency of the diaphragmatic pericardium, deficiency of the anterior diaphragm, and intracardiac anomalies). Various degrees of isolated sternal abnormalities have been described. The most common defect is failure of the sternal bars to fuse in the midline.[2] Nutritional deficiencies have been associated with skeletal deformities. Hague and Zaidi[2] described two cases of complete absence of the sternum in infants born to nomadic Saudi Arabian mothers. Both women lived in a region where essential vitamins were often absent from the diet. These authors suggested that chronic nutritional deficiencies, especially of riboflavin, may be associated with this skeletal anomaly. Our 14-year-old patient, socioeconomically disadvantaged female showed no signs of malnutrition.

Surgical repair of superior sternal clefting is usually performed as early as the infant's condition will permit. As the infant grows older, the cartilage becomes less malleable and the thoracic contents move anteriorly into the defect. In V-shaped defects the edges of the sternum can often be approximated by suture closure with relaxing osteotomy of the edges if needed. U-shaped defects often require transection of the limbs of the U at the juncture with the normal sternum, followed by suture approximation. Wire or synthetic mesh prosthesis or a bone graft may be required if the defect is very large or difficult to close.

To the best of our knowledge, this case is the first description of prenatal ultrasonographic findings associated with isolated clefting of the fetal sternum.

Bound volumes available to subscribers

Bound volumes of the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY are available to subscribers (only) for the 1992 issues from the Publisher, at a cost of $68.00 for domestic, $95.76 for Canada, and $91.00 for international for Vol. 166 (January-June) and Vol. 167 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the JOURNAL name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, USA; phone (800) 325-4177, ext. 4351, or (314) 453-4351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular JOURNAL subscription.

The presence of platelet-activating factor binding sites in human myometrium and their role in uterine contraction

Yan-ping Zhu, PhD,[a] R. Ann Word, MD,[b] and John M. Johnston, PhD[b]
Dallas, Texas

It has recently been suggested that platelet-activating factor is involved in a number of processes associated with reproductive biology. We have demonstrated a critical role for this autacoid in the initiation and maintenance of parturition both in animals and man. In the present investigation, it has been demonstrated that platelet-activating factor affects contraction in strips of human myometrium at concentrations as low as 10^{-10} mol/L. A platelet-activating factor receptor has been identified and characterized in human myometrium. Platelet-activating factor acts to cause an increase in intracellular Ca^{2+} concentration of isolated myometrial smooth muscle cells in culture and an increase in the phosphorylation of the 20 kd light chain of myosin in a concentration-dependent fashion. The presence of platelet-activating factor receptors in human myometrium, the observed increase in Ca^{+2} concentration and phosphorylation of myosin light chain in the presence of platelet-activating factor provide further support for the importance of this autacoid in the initation of parturition. (AM J OBSTET GYNECOL 1992;166:1222-8.)

Key words: Platelet-activating factor, myometrium, platelet-activating factor receptors, calcium, myosin light chain phosphorylation

Prostaglandins have been associated with reproductive biology since their discovery in the early thirties. More recently, a second autacoid, namely platelet-activating factor (1-O-alkyl-2-acetyl-*sn*-glycero-3-phosphocholine, PAF) has also been implicated in many of these processes, including ovulation,[1] sperm motility,[2] embryo implantation,[3] and the initiation of parturition and fetal lung maturation.[4, 5] In previous studies it was reported that PAF could be isolated and identified in amniotic fluid obtained from women at term and in active labor.[6] PAF was not present in amniotic fluid obtained from women at term who were not in labor. These observations were confirmed by Nishihira et al.[7] PAF affects contraction of rat,[7] guinea pig,[8] and human myometrium.[9] It has been suggested that PAF in amniotic fluid is, at least in part, of fetal lung origin.[10] PAF metabolism in the maternal compartment may also be important throughout gestation. The enzyme PAF acetylhydrolase catalyzes the inactivation of PAF to form lysoPAF. In the rabbit, the activity is decreased to 10% of the nonpregnant level in the maternal plasma during the last half of pregnancy.[11] After delivery, the PAF acetylhydrolase activity returns to prepregnancy levels within 24 hours. A decrease in PAF acetylhydrolase activity has also been demonstrated in the maternal plasma of the human.[12] It has been suggested that the combination of increased PAF synthesis in the fetal compartment, in combination with the decreased capacity of the maternal compartment to inactivate the autacoid, may promote delivery of PAF along with other autacoids, such as prostaglandins, to the myometrium, where they act to stimulate myometrial contractions.[13] PAF binding in endometrium has been characterized,[14] and the presence of a PAF receptor in rabbit myometrium suggested.

In the current investigation we report the presence of PAF receptors in human myometrium. We have also investigated the molecular basis of PAF action in human myometrial smooth muscle cells in culture by quantifying changes in the intracellular Ca^{2+} concentration and the extent of myosin light chain phosphorylation in these cells.

Material and methods

Human myometrial smooth muscle cells in culture. Human uterine specimens were obtained from premenopausal women at the time of hysterectomy performed for reasons other than endometrial or myometrial disease. Myometrial smooth muscle cells were isolated and maintained in primary and first-passage monolayer cultures as previously described[15] in Ham's F12–Dulbecco's minimal essential medium that contained fetal bovine serum (10%) and antibiotic-anti-

mycotic solution (10,000 U/ml penicillin G, 10,000 μg/ml steptomycin, and 25 μg/ml amphotericin B; 1% by content). Cells were incubated in a serum-free medium that contained human serum albumin (0.4%) for 16 hours before experiments.

Preparation of membrane fraction for PAF binding studies. Fresh human myometria denuded of endometrium were minced into very small pieces (1 to 3 mm^3) and then homogenized with a Polytron device (Kinematica, GmbH, Lucerne, Switzerland) for 3 minutes at 0° C in eight volumes (wt/vol) of prechilled Tris hydrochloride buffer (50 mmol/L, pH 7.6) at a setting of 5. Plasma membrane was prepared with a slight modification of the method previously described.[16, 17] The homogenate was filtered through two layers of cheesecloth, followed by centrifugation at 1000 *g* for 10 minutes at 4° C. The resulting pellet was resuspended in magnesium chloride (5 mmol/L), Tris (10 mmol/L), and ethylenediaminetetraacetic acid (2 mmol/L), pH 7.0, and fractionated on a discontinuous sucrose density gradient between 10%, 30%, 35%, 40%, and 50%. The membrane fragment used banded at the interface between the 35% and 40% sucrose solution. The specific activity of the plasma membrane marker enzyme[18] alkaline phosphatase had the highest specific activity in this fraction. This fraction had the highest PAF binding and was identical to the fraction reported for other tissues.[16, 17] The PAF receptor antagonist L-659,989 was used to further characterize the binding.[19] The membranes were stored at −80° C until use. No significant loss of tritium-labeled PAF specific binding was found during storage for up to 2 weeks. The protein concentration was determined by the method of Lowry et al.[20] with bovine serum albumin used as the standard.

PAF receptor binding assay. The specific binding of tritium-labeled PAF to the membranes of myometrium was assayed in a manner similar to that previously described by Hwang et al.[17] The membranes were suspended in magnesium chloride (10 mmol/L), Tris (10 mmol/L), and bovine serum albumin (0.25%) at pH 7.0. The suspension was incubated with tritium-labeled PAF in a total volume of 1 ml in the presence or absence of various concentrations of nonradioactive PAF (range 0.04 to 2.5 nmol/L) for 2 hours at 0° C. Nonspecific binding was determined by the addition of a 1000-fold excess on nonlabeled PAF. Binding was terminated by rapid vacuum filtration over a filter (HVLP 01300, Millipore Corp., Bedford, Mass.), followed by five 1.5 ml rinses with cold (4° C) buffer. The radiolabeled PAF present on the filter was counted by liquid scintillation spectrometry. The specific binding was computed as the difference between total binding and nonspecific binding. The PAF receptor antagonist studies were carried out with a method similar to that previously described.[19]

Quantification of intracellular Ca^{2+} concentration. The cultured cells were removed from the flask by treatment with Hank's balanced salt solution containing trypsin (0.05%, wt/vol, ethylenediaminetetraacetic acid (0.6 mmol/L), and Hepes (10 mmol/L, pH 7.4) for 5 to 8 minutes. The cells were then pelleted by centrifugation, washed two times, and incubated at 25° C for 15 minutes in culture medium that contained fura-2 acetoxymethyl ester (0.5 μmol/L). Thereafter, the cells were centrifuged, washed, and suspended a concentration of 1×10^6 cells per milliliter in buffer that contained potassium chloride (4.8 mmol/L), sodium chloride (130 mmol/L), magnesium chloride (1 mmol/L), calcium chloride (1.5 mmol/L), sodium phosphate (1 mmol/L), glucose (15 mmol/L), and Hepes (10 mmol/L, pH 7.4), as previously described.[21] Intracellular Ca^{2+} concentration was determined with a Perkin-Elmer 650-10S fluorescence spectrometer (Perkin Elmer, Norwalk, Conn.) by quantification of fluorescence with 340 nm excitation and 510 nm emission wavelengths, as described by Tsien et al.[22] and implemented in our laboratory.[21]

Determination of phosphorylation of light chain of myosin. The phosphorylation of myosin light chain was determined by densitometric analysis of myosin light chain (nonphosphorylated and monophosphorylated) that was visualized on immunoblots, as described.[23] The data are expressed as the percent of the total immunodetectable 20 kd myosin light chain that is phosphorylated.

Contraction of human uterine smooth muscle strips. Uterine longitudinal smooth muscle strips were prepared from the human uterus as described previously.[24] Before the addition to the test solution, individual strips were stretched to optimal length for force development and conditioned by a single contraction in physiologic saline solution that contained potassium chloride (65 mmol/L) substituted isotonically for sodium chloride. PAF was added to the incubation media in 2.5% bovine serum albumin that had been dissolved in normal saline solution and adjusted to pH 7.4. Control incubations contained bovine serum albumin alone.

Chemicals. Tritium-labeled PAF (1-O-[hexadecyl-1′-2′-^{3}H(N)]-2-acetyl-*sn*-glycero-3-phosphorylcholine), was purchased from New England Nuclear, Boston, with a specific activity of 10 Ci/mmol. Unlabeled C16-PAF was obtained from Avanti, Pelham, Ala., and from Sigma Chemical Co., St. Louis. L-659,989 was kindly supplied by Dr. J.C. Chabala of Merck Sharp & Dohme, Rahway, N.J.

Statistical analysis. The values given are the means ± SEMs.

Results

PAF receptor. The specific binding of tritium-labeled PAF to human myometrial plasma membrane was com-

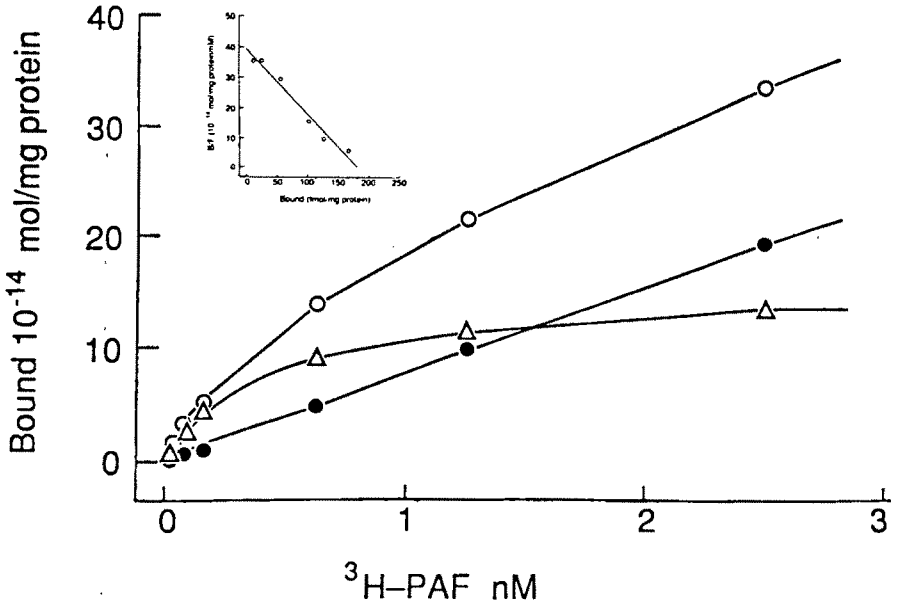

Fig. 1. Binding of tritium-labeled PAF to plasma membrane fraction prepared from human myometrium (○—○, total binding; ●—●, nonspecific binding; △—△, specific binding). *Inset*, Scatchard analysis of PAF receptor binding. Dissociation constant and maximal binding sites were 0.38 and 155.8 fmol/mg protein, respectively.

puted by the subtraction of the nonspecific binding from the total binding. The binding was determined with a 1000-fold excess of nonradiolabeled PAF (Fig. 1). Scatchard analysis of the PAF receptor for the human myometrium membranes is shown in the insert. This analysis is indicative of a single class of receptor sites for PAF in the membranes of myometrium. PAF receptor maximal binding sites of the human myometrial membranes was computed and found to be approximately 94.3 ± 25.2 fmol/mg protein. The mean equilibrium dissociation constant of PAF receptor of this sample of human myometrial membranes was 0.27 ± 0.05 nmol/L.

We also examined the effect of PAF receptor antagonist L-659,989 on the binding of PAF to the membrane fraction prepared from human myometrium. The membranes were incubated as previously described, with the exception that the PAF antagonist L-659,989 (6 nmol/L) was included in the experimental flasks.[19] A 50% inhibition of PAF binding was observed in myometrial membranes incubated in the presence of L-659,989. The inhibition was similar to that observed in other tissues.[19]

Effect of PAF on uterine contractility. Longitudinal uterine muscle strips from nonpregnant women were treated with PAF at a concentration of 2×10^{-10} mol/L. PAF acted to increase the active force of spontaneous contraction from 2.5 to 4.5 gm, and baseline tone increased from 1 to 3 gm for >20 minutes or until PAF was washed from the bath and replaced with salt solution (data not shown). Rhythmic contractions were superimposed on this elevation in baseline tone. The force of spontaneous contractions and the contractile force in response to PAF was determined by quantification of the area of active force during the 10 minute period just before and the 10-minute period after the addition of PAF. PAF induced a threefold increase in contractile activity. Previously, Tetta et al.[9] also reported a myometrial contractile response in human myometrial muscle strips of the lower uterine segment that were treated with PAF.

Effect of PAF on intracellular Ca^{2+} concentration and myosin light chain phosphorylation in myometrial cells in culture. PAF (10^{-14} to 10^{-10} mol/L) stimulated an increase in intracellular Ca^{2+} concentration (Fig. 2). PAF (10^{-10} mol/l) stimulated a threefold increase in intracellular Ca^{2+} concentration (from 112 to 301 nmol/L). The increase was transient with maximal values observed from 12 to 15 seconds, returning to basal levels by 60 seconds (Fig. 2, inset). Treatment of human myometrial smooth muscle cells with PAF resulted in an increse in phosphorylation of myosin light chain. In cells treated for 15 seconds with PAF at a concentration of 10^{-10} mol/L, myosin light chain phosphorylation increased from 3% (control) to 40% (Fig. 3).

Comment

Numerous investigations have been reported concerning the role of a variety of agents that effect the initiation and maintenance of parturition in various species, including the human. The role of various ei-

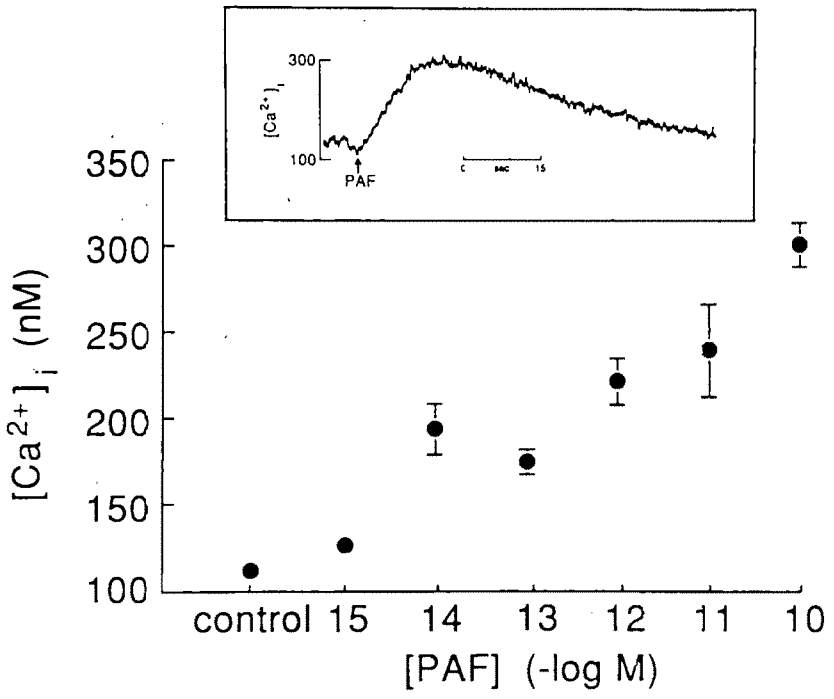

Fig. 2. Effect of PAF in intracellular Ca^{2+} in human myometrial smooth muscle cells. Data are expressed as mean ± SEM for 3 to 10 samples. *Inset*, Recording of fluorescence (340 nm) of fura-2-containing myometrial cells treated with PAF (10^{-10} mol/L). Data are represented as mean ± SEM.

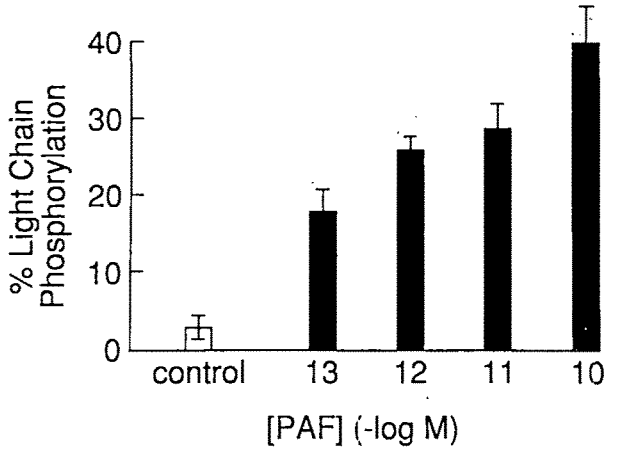

Fig. 3. Effect of PAF on myosin light chain phosphorylation in myometrial smooth muscle cells. Cells were treated with various concentrations of PAF. After 15 seconds, cellular protein was precipitated with trichloraacetic acid (10% wt/vol) and processed for immunoblot analysis after urea-glycerol gel electrophoresis, as described in Material and methods. Data are represented as mean ± SEM of extent (percent) of immunoreactive myosin light chain that is phosphorylated in three to four samples.

cosanoids in the events of parturition has been a major focus.[25, 26] Several years ago it was suggested that PAF may also play a role in this process, and the presence of PAF in the amniotic fluid of women at term and in labor was demonstrated.[6] It was suggested that the tissue origin of the PAF in amniotic fluid was the fetal lung[10] and kidney,[6] not the decidua.[27] The synthesis of PAF and the presence of PAF precursors were demonstrated in fetal membranes, but these tissues have limited capacity for PAF secretion.[28] The role of the fetal lung is implied by the fact that significant amounts of the PAF present in the amniotic fluid are associated with the surfactant-containing lamellar body fraction,[6] and an increase in PAF occurs in the rabbit fetal lung

during development.[10, 29] A direct role for PAF in surfactant biosynthesis was also suggested.[30, 31] PAF will also stimulate prostaglandin E_2 production in amnion tissue and cells.[32, 33] At later stages of gestation, when the fetal tissues have an increased capacity to synthesize PAF, there is a decreased capacity in the maternal plasma to inactivate PAF because of the decrease in plasma PAF acetylhydrolase activity.[11, 12] Early in pregnancy the small amounts of PAF synthesized may be prevented from reaching the myometrium by high circulating levels of maternal plasma PAF acetylhydrolase. The abundant blood supply of the decidua makes it a likely site for the inactivation of PAF.[13]

In the reported results we have confirmed the effect of PAF on the contraction of uterine smooth muscle and have demonstrated and characterized the PAF receptor in the plasma membranes of human myometrium. The characteristics of this receptor are similar to those reported for other tissues.[17] Kudolo and Harper[14] have demonstrated the presence of the PAF receptor in various uterine tissues of the rabbit. Although their efforts have focused primarily on the PAF receptor in the endometrium, they have noted that the receptor is present in the rabbit myometrium, albeit at a much lower density. The recent cloning of the PAF receptor from guinea pig lung,[34] a first among the various lipid mediators, provides further support for the concept that PAF exerts its action by a receptor-mediated event. In this study the receptor has been demonstrated and characterized from nonpregnant women. We have demonstrated previously that the administration of the PAF receptor antagonist L-659,989 to pregnant rats causes a prolongation of parturition.[35] We have concluded that L-659,989 also inhibits PAF binding to a membrane fraction prepared from human myometrium. This PAF receptor antagonist has been reported to be a rather specific inhibitor.[19] Thus the combination of these findings would provide further support for the suggestion that PAF is involved in parturition.[3]

We have also demonstrated that PAF will stimulate the contraction of strips of myometrium at relatively low concentrations (threefold at 10^{-10} mol/L). An increase in intracellular Ca^{2+} concentration and myosin light chain phopshorylation has been observed within seconds of the addition of PAF to human myometrial smooth muscle cells in culture. In most studies in which various agents have been used to stimulate uterine contraction, intracellular Ca^{2+} concentration increase, or myosin light chain phosphorylation, the concentration of the agonist used was between 10^{-6} and 10^{-9} mol/L.[36]

As indicated in Figs. 2 and 3, PAF stimulated Ca^{2+} uptake (Fig. 2) and the phosphorylation of myosin light chain (Fig. 3) at concentrations $<1 \times 10^{-10}$ mol/L. Thus it appears that PAF is one of the most potent stimuli of myometrial contraction. PAF is active in other systems at concentrations of 10^{-10} to 10^{-12} mol/L.[37, 38] The dissociation constant for PAF in the myometrial membranes used in this investigation is of the order of 10^{-10} mol/L. PAF acted to cause an increase in intracellular Ca^{2+} concentration in myometrial cells in culture in concentrations as low as 10^{-14} mol/L. Additional mechanisms must be invoked to account for the mechanism of action of PAF. Recently it has been reported that the PAF receptors present in the plasma membrane of various different cell types are heterogeneous.[39] In addition, this group of investigators has demonstrated the presence of the intracellular receptors in certain tissues.[39] The existence of PAF receptors of the intracellular type in human myometrium and their possible role in the contractile processes is presently under investigation.

In summary, we have demonstrated a receptor for PAF in human myometrium and that human myometrial smooth muscle cells in culture respond to PAF with an increase in intracellular Ca^{2-} concentration and myosin light chain phosphorylation. The PAF receptor antagonist L-659,989 blocks the PAF binding to the membrane fraction. On the basis of these findings and previously published observations,[12, 13] it is suggested that PAF may play an important role in conjunction with other autacoids in the initiation and maintenance of parturition.

We thank M. Linette Casey (Southwestern Medical School, Dallas, Texas) for assistance in the culture of human myometrial smooth muscle cells, and James T. Stull (Southwestern Medical School, Dallas, Texas) for the polyclonal antibody to myosin light chain. The assistance of Melanie King, RN, and Valencia Hoffman in obtaining tissues is appreciated.

Effects of platelet-activating factor on prostaglandin E_2 production by intact fetal membranes

Christine Morris, MB, BS, Haroon Khan, MD, Mark H.F. Sullivan, PhD, and M.G. Elder, MD

London, England

OBJECTIVE: The hypothesis tested in this study is that platelet-activating factor increases prostaglandin E_2 synthesis from fetal membranes.

STUDY DESIGN: Fetal membrane disks obtained before or after labor were incubated with or without platelet-activating factor for time periods of up to 24 hours. The production of prostaglandin E_2 and its inactive metabolites was determined by specific radioimmunoassays.

RESULTS: Platelet-activating factor (1 to 10 μmol/L) stimulated the production of prostaglandin E_2 and its metabolites by intact fetal membranes and chorion-decidua threefold to fourfold after 24 hours of incubation. Platelet-activating factor had far greater effects on the production of prostaglandin E_2 by intact fetal membranes obtained after the onset of labor, such that prostaglandin E_2 production was increased by tenfold to 100-fold.

CONCLUSION: These results suggest that platelet-activating factor mainly stimulates prostaglandin E_2 production by the chorion-decidua before labor and that it may act in synergism with other stimulatory factors present in the fetal membranes during labor. (Am J Obstet Gynecol 1992;166:1228-31.)

Key words: Platelet-activating factor, fetal membrane, labor, prostaglandin E_2

The control of normal term human labor and delivery has been extensively studied over the last 15 to 20 years, and although the role of prostaglandins E_2 (PGE_2) and $F_{2\alpha}$ has been established unequivocally,[1, 2] relatively little progress has been made beyond this point. The measurement of increased prostaglandin (and prostaglandin metabolite levels) in preterm and term labor,[3, 4] together with the ability of endogenously administered prostaglandins to initiate labor and delivery,[5] has shown that these compounds have a focal role in the process of labor. However, the factors that control intrauterine prostaglandin production remain to be identified, although activation of the immune response and the release of cytokines have been implicated in preterm labor associated with infection.[6-8] The similarities between pathologic preterm labor and the normal, term process remain unclear, although small increases in cytokines have been shown in amniotic fluid obtained from women with term labor,[6, 8] but definitive data linking these stimuli with the initiation of labor are lacking.

Platelet-activating factor (PAF, 1-O-alkyl-2-acetyl-*sn*-glycero-3-phosphocholine), a bioactive lipid, has been implicated in labor by the finding that PAF levels in amniotic fluid are elevated in both term and preterm labor.[9-11] PAF is a component of fetal urine and may be secreted by the maturing fetal lung[12]; it may also be released by decidual activation associated with intrauterine infection.[13, 14] The synthesis of PAF is integral to the normal immune response to infective agents,[13, 14] so the production of PAF during preterm labor associated with infection is likely to be part of this general reaction rather than a specific initiation of labor. In term labor the synthesis of PAF from specific tissues[12] may be directed to initiate labor. PAF is known to increase prostaglandin production by a number of tissues,[15, 16] so we investigated the effects of PAF on the production of PGE_2 by cultured intact fetal membrane, the amnion, and the chorion-decidua.

Methods and material

Fetal membranes were obtained after delivery either by elective cesarean section or by normal term labor and vaginal delivery. Fetal membrane disks were prepared and cultured as described elsewhere.[17] In brief, the membranes were cultured on the ends of glass cylinders (outside diameter 14 mm) and held in place by silicone rubber rings (J. Walker & Co., Ltd., Woking, Surrey, England). Excess membrane was removed with a scalpel. Silicone rubber washers (J. Walker) were placed on the other end of the cylinder to support the glass cylinders from the lid of a 12-place multiwell plate

in which holes with a diameter of 24 mm had been drilled. Tissue culture medium (1.5 ml) was then added to each side of the membrane, to produce a two-compartment experimental system. One compartment was in contact with the amnion (fetal side), and the other was in contact with the chorion-decidua (maternal side). The medium used was medium 199 with antibiotics (Gibco, Paisley, Scotland), 10% heat-inactivated horse serum (Gibco), and 1% L-glutamine (Gibco). An intact multiwell lid was placed over the top of the system to maintain sterile culture conditions, and the culture system was incubated at 37° C in 95% air and 5% carbon dioxide. In all the experiments a 24-hour period of incubation was used before any further experimentation to allow the membrane to recover from the trauma of delivery and the laboratory procedures. Cell membrane integrity was tested with diaphorase histochemical staining,[18] and this was used as an assessment of the viability of the cells in the fetal membranes.[17]

PAF (from Sigma Chemical Co., Poole, Dorset, England) at concentrations from 1 pmol/L to 10 μmol/L was added to either the maternal side, the fetal side, or both sides of the membrane, and the incubation was continued for various times from 4 to 24 hours, after which the medium was removed and frozen at −20° C until measurement of PGE_2 and its metabolites by radioimmunoassays.[19] In some experiments the membrane was split before culture, and separated amnion or chorion-decidua was cultured in the same way as intact fetal membrane. Differences in the production of PGE_2 and its metabolites were assessed by two-way analysis of variance. The radioimmunoassay for PGE_2 was an "in-house" technique, with PGE_2 standard and PGE_2 antibody from Sigma Chemical Co. and tritiated PGE_2 and scintillation proximity assay reagent from Amersham International (Aylesbury, Buckinghamshire, England). PGE_2 metabolites were measured with a kit from Amersham International.

Results

In the initial experiments platelet-activating factor was added simultaneously at the same concentration to both sides of the fetal membrane, and total PGE_2 production on both sides of the membrane was determined. PAF stimulated PGE_2 production by cultured amnion maximally at a concentration of 0.1 μmol/L after 24 hours of incubation (Fig. 1). At shorter incubation times, PAF stimulated smaller increases in PGE_2 production (results not shown). Higher concentrations of PAF (1 to 10 μmol/L) were required to stimulate PGE_2 production from intact fetal membrane (Fig. 1) and chorion-decidua (results not shown). In subsequent experiments the intermediate concentration of 5 μmol/L PAF was used to stimulate PGE_2 production from intact fetal membranes or chorion-decidua.

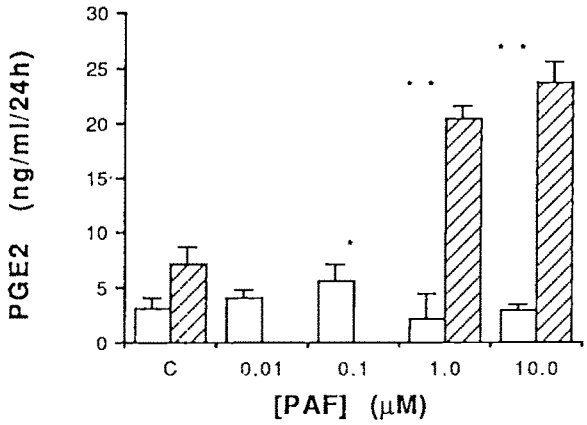

Fig. 1. Production of PGE_2 from amnion *(open box)* or intact fetal membrane *(hatched box)* in response to different concentrations of PAF added simultaneously to both sides of membrane. All data are means ± SEM ($n = 4$) and are representative of three experiments. *One asterisk*, $p < 0.05$ (vs control); *two asterisks*, $p < 0.01$ (vs control).

Further studies on intact fetal membranes showed that PAF added to the amnion side of the intact membrane had little effect on PGE_2 production (Fig. 2, *A*) whereas PAF added to the decidual side of the membrane stimulated PGE_2 production fourfold (Fig. 2, *A*). The addition of PAF to both sides of the fetal membrane increased PGE_2 production on the decidual side, whereas PGE_2 metabolite was increased on both sides of the membrane (Fig. 2, *B*), which suggested that the increase in PGE_2 was unlikely to be due to a decrease in the rate of metabolism. Similar threefold to fivefold increases in PGE_2 and PGE_2 metabolite levels were found when PAF was added to the decidual side of cultured chorion-decidua (results not shown).

Intact fetal membranes obtained after labor produced basal levels of PGE_2 that were higher (Fig. 3) than those in the corresponding tissue obtained before labor (Fig. 2). PAF (5 μmol/L) further increased PGE_2 production more than tenfold, such that PGE_2 production exceeded 100 ng in 24 hours (Fig. 3) but only when it was added to the decidual side of the membrane. PAF added to the amnion side had no effect, and the addition of PAF to both sides of the membrane had less effect than PAF added to the decidual side alone (Fig. 3).

Comment

PAF has been implicated in labor by the finding that increased levels of this substance are present in amniotic fluid during both preterm and term labor,[11] but the sources of this PAF have not been identified. The increased levels of PAF may come from the maturing fetal lung,[12] which may be of importance in term labor, or from activation of the immune response after intra-

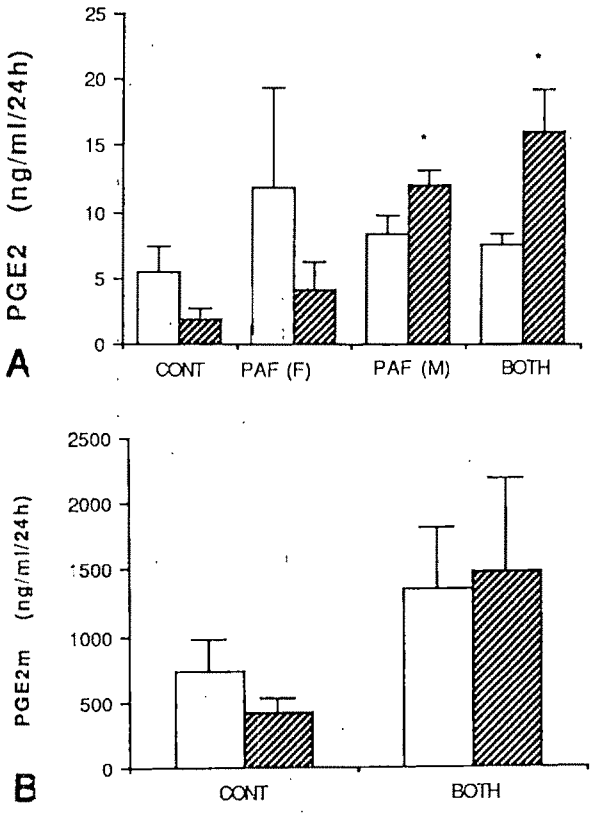

Fig. 2. Production of PGE_2 **(A)** or PGE_2 metabolites **(B)** by intact fetal membranes in presence or absence of PAF (5 μmol/L). PAF was added to fetal *(F)*, maternal *(M)*, or both sides of membrane as shown; and prostaglandin production was measured in medium in contact with amnion *(open box)* or chorion-decidua *(hatched box)*. All data are means ± SEM ($n = 3$) and are typical of three experiments. *One asterisk*, $p < 0.05$ (vs control).

uterine infection,[13, 14] which would be relevant to preterm delivery. Regardless of source, PAF could then stimulate intrauterine prostaglandin production, as it is known to do in other tissues,[15, 16] and thus be of focal importance in the process of labor. It is also possible that PAF may be produced by decidual macrophages activated as part of the process of labor.[20] Thus increased PAF production would be indicative of the process of labor, rather than an initiator of it.

Our results suggest that PAF affects prostaglandin production by the intact fetal membrane in a complex manner. PAF stimulated a small increase in the production of PGE_2 from the amnion but had a more potent effect on the production of both PGE_2 and PGE_2 metabolites from the intact fetal membrane and chorion-decidua. It would therefore seem that most of the PGE (PGE_2 plus metabolites) produced by the stimulated intact fetal membrane originates in the decidua, because the amnion alone contributes 10 to 20 ng/ml/24 hours (Fig. 1) compared with 1000 to 2000 ng/ml/24 hours (Fig. 2, *B*) from the intact membrane. This is consistent with other studies that indicate that most of the PGE produced by intact fetal membranes is detected as inactive metabolites[19, 21] and may originate in the decidua. In addition, PAF added to the decidual side of the intact fetal membrane stimulated PGE_2 production to a greater extent than PAF added to the amnion side of the membrane, which is consistent with other reports implicating the decidua in prostaglandin production during labor.[20, 22]

Intact fetal membranes obtained after labor showed a higher basal level of PGE_2 production, especially on the amnion side (Fig. 3), which is consistent with other reports indicating increased production of prostaglandins by amnion after labor.[23, 24] The addition of PAF to the amnion side of the membrane had no effect, whereas PAF added to the decidual side stimulated PGE_2 production by sixfold to tenfold on both sides of the membrane (Fig. 3). These results suggest that, although PAF can increase PGE_2 production by the amnion, the major effects of PAF are on the decidua when the intact fetal membrane is used. In addition, PAF stimulated very high levels of PGE_2 production after labor, which suggests that it may interact with factors in the fetal membrane after labor to stimulate prostaglandin production. Further studies are under way to assess which of the cell types present in the decidua (macrophages, stromal cells, and lymphocytes)[25] respond to PAF by increasing PGE_2 production.

These results indicate that PAF per se does not initiate the process of labor but rather may be an important factor in the maintenance of the elevated prostaglandin production integral to the process of labor. Further studies are needed to identify the factor or factors that act in synergism with PAF to increase fetal

membrane prostaglandin production. PAF added to the amnion side of the intact fetal membrane had little effect on PGE_2 production, which suggests that PAF in amniotic fluid, which may be fetal in origin, may have only a limited role in the initiation of labor. PAF produced by activated decidual macrophages may therefore be involved in the process of labor, so the control of the synthesis of PAF by these cells requires further investigation.

Papanicolaou smear abnormalities in ambulatory care sites for women infected with the human immunodeficiency virus

Carola Marte, MD, Patricia Kelly, CNP, Mardge Cohen, MD, Rachel G. Fruchter, PhD, Alexander Sedlis, MD, Leza Gallo, MD, Vera Ray, MD, and Carolyn A. Webber, MD

New York and Brooklyn, New York, and Chicago, Illinois

OBJECTIVE: We attempted to determine the prevalence of cervical dysplasia in human immunodeficiency virus–infected women in ambulatory care settings and to correlate Papanicolaou smears with demographic and clinical variables.

STUDY DESIGN: Papanicolaou smears of 135 women attending three ambulatory care clinics were reviewed. Chart review identified demographic and clinical variables, including CD4 count. Prevalence of abnormal smears was compared with baseline community rates. Demographic and clinical variables were correlated with Papanicolaou results with the χ^2 test.

RESULTS: Fivefold to eightfold increased rates of abnormal smears in human immunodeficiency virus–infected women were observed. Prevalence of abnormal smears increased from 21% in women with CD4 counts >600/mm³ to 45% in women with CD4 counts <400/mm³. Age, ethnicity, or mode of human immunodeficiency virus transmission was not significantly correlated with Papanicolaou smear findings.

CONCLUSION: Increased rates of abnormal Papanicolaou smears and significant correlation with CD4 counts were observed in human immunodeficiency virus–infected women at ambulatory care sites. We recommend comprehensive gynecologic care, including semiannual Papanicolaou smears, for all human immunodeficiency virus–infected women. (Am J Obstet Gynecol 1992;166:1232-7.)

Key words: Human immunodeficiency virus, acquired immunodeficiency syndrome, cervical cytology, Papanicolaou smears, CD4 lymphocytes

Human immunodeficiency virus (HIV) infection and acquired immunodeficiency syndrome (AIDS) are now increasing more rapidly in women than in men in the United States.[1] Conditions unique to women, notably gynecologic conditions, are beginning to gain recognition. However, because of the focus on HIV treatment in the setting of infectious disease specialization, women's primary care needs, including gynecologic care, have received less attention than they should.

Cervical dysplasia is of particular concern because of its potential for malignant development. Given that cervical neoplasia is known to be more common and more aggressive in iatrogenically immunodeficient women such as renal transplant patients,[2] cervical Papanicolaou test screening and information on cervical dysplasia are of particular importance in the growing population of women with HIV-associated immunodeficiency.

This study was stimulated by the concern of primary care providers in three different ambulatory sites for HIV-infected women. Subjective impressions of a high frequency of abnormal smears and genital warts among our patients and early reports of associations between cervical neoplasia and HIV disease[3-5] led us to initiate this multicenter study of cervical cytologic results and immunodeficiency. The goal of this study was to ascertain the prevalence of cytologic abnormality in HIV-infected women and to explore the relationships between associated variables including mode of HIV transmission, demographics, immune status, and HIV disease stage.

Methods

Three ambulatory care facilities offering comprehensive primary care to HIV-infected persons initiated a program of consistent gynecologic services and gathered routine gynecologic data for comparison. The sites were The Women and Children with AIDS Project at Cook County Hospital, Chicago, the Infectious Disease Clinic at Kings County Hospital, Brooklyn, and the Community Health Project, a satellite facility of Bellevue Hospital, New York.

At each of the three sites a protocol for routine gynecologic care was introduced that called for pelvic examination with Papanicolaou test and screening for sexually transmitted diseases (STDs) every 6 months. All women were informed of the protocol and the rationale

for its use and were offered gynecologic services at the clinic sites.

Pelvic examinations were performed and specimens were obtained for cervical cytologic testing (Papanicolaou test). Serum syphilis screening and gonorrhea culture were obtained in all cases; chlamydia assay and wet mount for *Candida* and trichomonas identification were obtained as indicated at each site.

Patients' charts were reviewed to obtain data on age, race or ethnicity, test results for chlamydia, gonorrhea, and syphilis, the original cytology report, mode of HIV transmission, stage of HIV disease, and CD4 lymphocyte counts obtained within 2 months of cytologic testing. Race or ethnicity was defined as African American, Latina, and European American with each category including both those born in the United States and immigrants.

Cytology slides were read by each institution's cytology staff who were unaware of the subjects' HIV status. Slides were reviewed by a fourth independent cytologist experienced in interinstitutional studies. Several slides from women with unknown HIV status were included to ensure a blinded review. The reviewer was not aware of the original cytologists' reports. The interpretation of the reviewer was used for the 113 slides reviewed, whereas the original interpretation was used for the 22 slides not available for review.

Smears were categorized according to the Bethesda system.[6] Slides were considered to show abnormality if they were reported as containing atypia of uncertain significance, low-grade squamous intraepithelial lesions (human papillomavirus, mild dysplasia), or high-grade squamous intraepithelial lesions (moderate and severe dysplasia, carcinoma in situ). Papanicolaou tests indicating inflammatory atypia or infection by any organism other than human papillomavirus were categorized as normal.

A baseline rate for "abnormal" Papanicolaou tests was obtained from the cytology service of each site. In each case this baseline rate consisted of the rate of abnormal Papanicolaou tests for outpatients attending routine medical, gynecologic, and obstetrics clinics. The baseline estimate did not include hospitalized patients or those attending specialty clinics such as oncology clinics.

Differences in proportions were estimated by the χ^2 test and the Fisher exact test. The degree of concordance between original and reviewed cytologic results was estimated with the κ statistic and the degree of skewness by a modified McNemar test for symmetry.

Results

The ambulatory care sites varied considerably with respect to race or ethnicity, mode of HIV transmission, and severity of immunodeficiency as judged by CD4 lymphocyte count (Table I). There was no difference with respect to age. Kings County Hospital subjects differed from those at Community Health Project and Cook County Hospital in having more severe immunodeficiency as measured by CD4 counts and in that only one quarter had been intravenous drug users. Community Health Project subjects differed from those

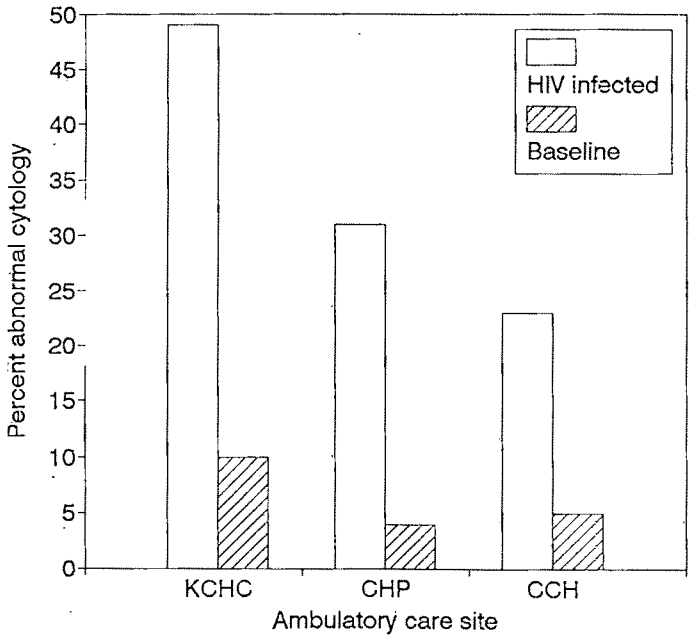

Fig. 1. Percent of HIV-infected women with cytologic abnormality compared with baseline rate at each ambulatory care site. *KCHC*, Kings County Hospital Center; *CHP*, Community Health Project; *CCH*, Cook County Hospital.

at Kings County Hospital and Cook County Hospital in that 60% were European American.

The frequency of abnormal smears was compared with the baseline rate at each institution according to the original criteria of each laboratoy (Fig. 1). In HIV-infected women the rate of abnormal Papanicolaou test results was 23% at Cook County Hospital, 48% at Kings County Hospital, and 32% at Community Health Project. While the baseline rate varied with each site, the rates in HIV-infected women were consistently fivefold to eightfold higher than the corresponding baseline rates.

Cytology slides were reviewed for 82% of Cook County Hospital subjects, 86% of Community Health Project subjects, and 86% of Kings County Hospital subjects. With the classification of normal versus abnormal, there was complete concordance between reviewer and original at Kings County Hospital. For Community Health Project two smears were reclassified from normal to abnormal, but the κ statistic of 0.84 indicated excellent agreement beyond chance. For Cook County Hospital eight slides were reclassified from normal to abnormal and two from abnormal to normal, and the κ statistic of 0.56 indicated fair to good agreement beyond chance. Overall, there was a significant tendency ($p = 0.02$ in McNemar's symmetry test) for the reviewer to upgrade normal results to abnormal ones.

The relation between selected patient characteristics and the frequency of cytologic abnormality is shown in Table II. There was no significant difference in the proportion of abnormal smears by age, race or ethnicity, ambulatory care site, or mode of HIV transmission. A difference that approached, but did not reach, statistical significance was that none of the five women with transfusion-acquired HIV infection had cytologic abnormality ($p = 0.08$ in Fisher exact test).

Overall, 41% of 134 subjects had CD4 counts $<200/mm^3$, 23% had counts of $200/mm^3$ to $399/mm^3$, 18% had counts of $400/mm^3$ to $599/mm^3$, and 17% had counts $>600/mm^3$. Women with CD4 counts $<400/mm^3$ had nearly a twofold higher prevalence of cytologic abnormality than women with higher CD4 counts (45% vs 26%). Although CD4 counts >600 were associated with the lowest proportion of abnormal smears, CD4 counts <200 were associated with the same rate of abnormal smears as CD4 counts of 200 to 399 (Fig. 2).

The proportion of women with both AIDS and cytologic abnormality was higher, but not significantly, than the proportion of HIV-infected women without AIDS but with cytologic abnormality. There was no difference in abnormality rates between those with symptomatic HIV disease and those without symptoms. In this series only six women had cytologic results indicative of high-grade squamous intraepithelial lesions. Of the six, four had CD4 counts <200 and two had CD4 counts between 200 and 399.

Low rates were found for active syphilis, gonorrhea, and chlamydia: 5 of 135 (4%) required treatment for

Comment

Two significant findings emerge from this study. First is the high rate of cytologic abnormality compared with baseline rates in each of three demographically and geographically distinct ambulatory care centers. Second is the association between severity of immunodeficiency and frequency of cytologic abnormality.

Since this study was initiated, the association between HIV infection and cytologic abnormality has been confirmed in several studies[7-9] with odds ratios of about 5. Our finding of a fivefold to eightfold increase in cytologic abnormality in HIV-infected women over the baseline rate at each site is consistent with these other studies.

Two prior studies suggest that increased rates of cervical neoplasia are associated with increased immunodeficiency. Maiman et al.[10] found increasing rates of histologically confirmed cervical intraepithelial neoplasia as CD4 count decreased in 32 HIV-infected women. Schafer et al.[7] showed an association between lowered CD4 counts and increased prevalence of cytologic abnormality. Their results were similar to ours in the finding of a significantly higher prevalence of Papanicolaou test abnormalities in women with CD4 counts <400/mm^3 but no significant difference in abnormality rates within subgroups with CD4 counts <400/mm^3.

Several explanations for the association between HIV infection and cytologic abnormality may be proposed. Most cytologic abnormality is associated with infection by human papillomavirus, and human papillomavirus infection may have a more aggressive course in HIV-infected women than in immunocompetent individuals. It is known that immunosuppression in HIV-infected men and women places them at risk for unusually frequent or severe manifestations of certain other viral infections, for example, cytomegalovirus and herpes simplex virus. Increased frequency of human papillomavirus and associated anogenital neoplasia has been reported in HIV-infected men.[11, 12] Other immunodeficiency states resulting from congenital and iatrogenic factors are also associated with high rates of cervical neoplasia.[2, 13] In addition, an association between HIV infection and cervical dysplasia would be expected on the basis of common sexual risk factors since both cytologic abnormality and HIV infection are associated with having multiple sexual partners. In this study we did not have information on the sexual behavior histories of the women and therefore could not control for sexual behavior.

There is a growing consensus among clinicians that Papanicolaou test screening for cervical intraepithelial neoplasia must become a routine part of care for HIV-infected women and that treatment for human papil-

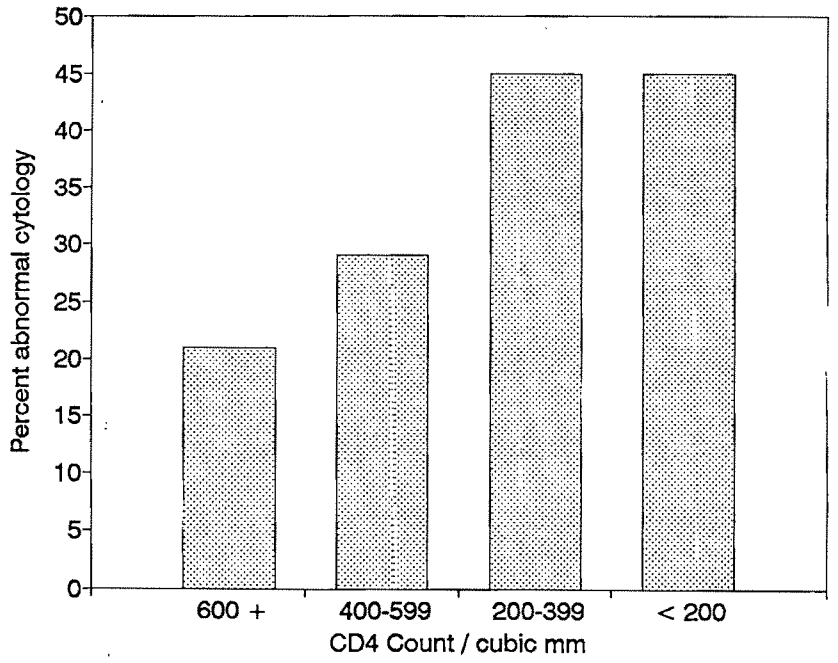

Fig. 2. Percent of cytologic abnormality by CD4 count. (Cytologic results reviewed by independent reviewer.)

lomavirus–related disease should be at least as careful as, or even more aggressive, than for uninfected women. There is still little information on the natural history of cervical disease in HIV-infected women on which to base guidelines for the proper interval for screening.[14] However, because of the indication that cervical disease may be more aggressive in the presence of HIV infection[13] and because of possible disordance between cytologic and histologic results,[10] we recommend that HIV-infected women have Papanicolaou tests at 6-month intervals rather than annually until the appropriate interval is clearly established. In addition, we recommend that all women with both low-grade and high-grade squamous intraepithelial lesions (grades 1 to 3 cervical intraepithelial neoplasia) on cytologic test results be referred for immediate colposcopy for the same reasons. The treatment of choice for cervical abnormalities in HIV-infected women has yet to be investigated. However, close and frequent follow-up after standard treatment is advisable because of the potential for recurrence.

The purpose of Papanicolaou test screening is to identify and treat cervical neoplasia at an early stage, preventing the development of invasive cancer and associated mortality. The course of cervical neoplasia in HIV-infected women must be evaluated since the immunodeficiency that allows a high prevalence of cervical disease may also allow rapid progression and poor response to therapy. As treatment of HIV-associated conditions becomes more effective and the lives of HIV-infected women are prolonged, the need to prevent the development of life-threatening cancer becomes more critical.

The clinical implications for women are clear. First, infectious disease specialists and other clinicians caring for HIV-infected women should ensure that their patients receive appropriate gynecologic care. Second, in areas with high rates of HIV disease, women with abnormal Papanicolaou test results should be considered at risk for HIV infection and should be offered confidential HIV counseling and testing.

Intravenous nitroglycerin for uterine relaxation of an inverted uterus

Kenneth M. Altabef, MD, James T. Spencer, MD, and Stanley Zinberg, MD
New York, New York

Intravenous nitroglycerin has recently come to the attention of obstetricians as a potent uterine relaxant. In the case presented, it was used to permit replacement of a tightly contracted, inverted uterus. Relaxation was rapid, effective, and associated with no adverse side effects. (AM J OBSTET GYNECOL 1992;166:1237-8.)

Key words: Nitroglycerin, uterine inversion

Since the first synthesis of nitroglycerin in 1846, it has found many uses among specialists in internal medicine. These include therapy for acute episodes of angina, ischemic heart disease, unstable angina syndrome, congestive heart failure, and control of acute hypertension during cerebrovascular and coronary surgery. The safety, predictability, and ease of intravenous administration of this drug have been firmly documented. In recent years intravenous nitroglycerin has come to the attention of the obstetrician as a potent uterine relaxant. This case describes its use to enable replacement of a completely prolapsed, inverted uterus.

Case report

The patient was a 27-year-old Chinese woman, gravida 3, para 1, abortus 1, admitted at 40 weeks of gestation with onset of labor. Prenatal course was significant for gestational diabetes controlled by dietary measures. Medical and surgical history was negative. The patient was admitted in active labor at 4 cm dilatation with contractions every 10 minutes. Artificial rupture of membranes was performed; over the next 4 hours the cervix progressed to full dilatation, and she was taken to the delivery room. Blood pressure throughout labor was 100/70 mm Hg. Normal spontaneous vaginal delivery ensued over a right mediolateral episiotomy. With traction on the cord and Brandt maneuver to secure the uterus, delivery of the placenta was attempted. With the bulk of placenta at the introitus the patient appeared to be in an unusual amount of pain for delivery of the placenta. It was then noted that the uterus was external to the introitus. The placenta was tightly adherent to the inverted, completely prolapsed uterus.

It was decided to attempt uterine relaxation with intravenous nitroglycerin, as opposed to general anesthesia. Nitroglycerin 50 μg was administered intravenously, and within 90 seconds moderate uterine relaxation was noted but it was not sufficient to effect replacement of the uterus. Sedation with 10 mg keta-

6/1/35382

mine given intravenously was also used. An additional 50 μg dose of nitroglycerin was administered, and complete uterine relaxation was achieved. The placenta was easily stripped from the endometrium, and the uterus was replaced with the assistance of the operator's fist. The relaxation was reversed within 2 minutes by uterine massage, intravenous oxytocin, and intramuscular ergotrate, and the uterus contracted. Episiotomy was then repaired. Vital signs were monitored by an automated blood pressure cuff and electrocardiogram. Blood pressure was 90/60 mm Hg and pulse 130 beats/min with uterine inversion, 95/55 mm Hg and 140 beats/min after the initial dose, 85/55 mm Hg and 130 beats/min after the repeat dose, and 100/55 mm Hg and 130 beats/min on transfer to the recovery room. There was a blood loss of 1800 ml that necessitated transfusion.

Comment

Uterine inversion, a serious and often unexpected obstetric complication, has a reported incidence of 1 in 2000 deliveries. Inversion is associated with excessive hemorrhage and shock. Traditional management includes prompt replacement of the uterus, vigorous hydration and transfusion, and often the use of general anesthetics to provide relaxation of the pregnant uterus. This course has significant risks, especially in pregnancy, where the risk of aspiration of gastric contents is markedly increased. Halothane is a cardiodepressant and is often associated with hypotension.

Nitroglycerin has been shown to be an effective relaxant of strips of rat myometrium in vitro, but there are few reports of the use of intravenous nitroglycerin for uterine relaxation in humans. Peng et al.[1] reported their experience with intravenous nitroglycerin for manual removal of the placenta in 15 patients where the cervix had contracted. In that report a dose of 500 μg was used, with success in all cases. However, at that dosage a statistically significant, although clinically unimportant, reduction in blood pressure was noted. Side effects such as headache and prolonged uterine relaxation were not observed.

In another report, DeSimone et al.[2] described the use of a 50 to 100 μg dose in 22 patients who required uterine muscle relaxation for manual removal of the placenta when the uterus was firmly contracted around the cord. In all cases relaxation was achieved with no clinically significant changes in blood pressure or heart rate. No patient complained of headache, palpitations, or other subjective effects.

This is the first reported case of intravenous nitroglycerin for use in patients with an inverted uterus. It is ideal for such a situation because of its powerful uterine relaxant effect and short plasma half-life (2 minutes). With the low doses of nitroglycerin used, the degree and duration of uterine relaxation can be controlled easily and without maternal side effects. In this way the significant risks of general anesthesia may be circumvented.

Severe anti-C hemolytic disease of the newborn

John M. Bowman, MD,[a] Janet M. Pollock, RT,[a] Frank A. Manning, MD,[b] and Chris R. Harman, MD[b]
Winnipeg, Manitoba, Canada

OBJECTIVE: Because of referral of a C-alloimmunized pregnant woman with a previous hydropic death whose fetus survived after four intraperitoneal transfusions, prevalence and severity of anti-C hemolytic disease of the newborn were investigated.
STUDY DESIGN: The numbers of C- or Ce-alloimmunized pregnancies in Manitoban women and their outcome for the 28-year period ending Oct. 31, 1990, were reviewed. The literature relating to C or Ce alloimmunization from 1944 to 1990 was surveyed.
RESULTS: In Manitoba for the period reviewed there were 120 pregnancies in 80 C- or Ce-alloimmunized women. Twenty-two ended in abortion and two in fetal death unrelated to anti-C or anti-Ce. Of the remaining 96, 33 fetuses of 32 pregnancies were affected but only eight (6.7%) required treatment after birth. None were severely affected. In the literature there are only three other reported deaths from C or Ce hemolytic disease; two of the three may have been the same patient. The prevalence of C or Ce alloimmunization reported in various series, including our own, ranged from 8.7 to 185 per 100,000 pregnancies.
CONCLUSIONS: Because on rare occasions, C or Ce alloimmunization can cause severe hemolytic disease, criteria for investigative measures such as amniocentesis or cordocentesis do not differ from the criteria for instituting these measures in Rh_o (D)–alloimmunized pregnancies. (Am J Obstet Gynecol 1992;166:1239-43.)

Key words: Anti-C hemolytic disease, fetal transfusions

Although anti-C is listed as an antibody capable of causing severe hemolytic disease of the newborn,[1] reports of anti-C causing severe hemolytic disease are extremely rare. In 1986 the Rh Laboratory and the Division of Fetal and Maternal Medicine, Faculty of Medicine, University of Manitoba, and the Health Sciences Centre, Winnipeg, participated in the management of an anti-C alloimmunized pregnant women whose fetus required intrauterine transfusions to survive. In 46 years of experience with maternal alloimmunization, this was the Rh Laboratory's first example of anti-C hemolytic disease of such severity. We report this case in detail, with a review of the Rh Laboratory experience and the experience of others with anti-C or anti-Ce alloimmunization.

Case report

At the time of her first pregnancy this para 2, gravida 3, group A, Rh-positive, C-negative, Cw-negative, e-negative (R^2R^2) woman was transfused at cesarean section for abruptio placentae. Her second pregnancy ended at 37 weeks' gestation with a hydropic stillbirth. At that time she was found to have very strong anti-C and anti-Cw and very weak anti-e blood group antibodies. Her husband was group B, Rh positive, C positive, e positive, and Cw negative (R^1R^1). Thus anti-C was the alloantibody responsible for the hydropic fetal death.

Mrs. S. was referred to Winnipeg in 1986, in her third pregnancy at 22½ weeks' gestation. The anti-C titer was 256 in albumin and 1 in saline solution. Two amniocenteses had been carried out at the referring center, the Δ optical density readings at 450 nm (ΔOD_{450}) were 0.355 and 0.362 at 20½ and 22½ weeks' gestation. Two days later in Winnipeg, at the time of the first intraperitoneal fetal transfusion, the ΔOD_{450} reading was 0.346. Hepatomegaly was evident on ultrasonography, but the fetus was not hydropic.

Four intraperitoneal fetal transfusions were carried out with infusion of tightly packed, fresh, compatible, group O, C-negative, Cw-negative, e-negative (R^2R^2), Kell-negative red blood cells at 22½, 24, 27½, and 31 weeks' gestation.

She was delivered of a female infant by elective cesarean section at 33½ weeks' gestation in the tertiary-level center from which she had been referred. Jaundice was present and there was marked hepatosplenomegaly. Cord red blood cells were 99.7% adult donor in origin by Kleihauer acid elution testing. Cord hemoglobin level was 117 gm/L; cord serum bilirubin level was 138 μmol/L total and 38 μmol/L by direct reaction.

Table I. Anti-C or anti-Ce alloimmunization, Manitoba, Nov. 1, 1962, to Oct. 31, 1990
475,000 pregnancies

Anti-C or anti-Ce immunized women	*Total anti-C or anti-Ce pregnancies*	*Abortions and unrelated losses*	*Unaffected (direct antiglobulin test–negative) infants*	*Affected, no treatment required*	*(Direct antiglobulin test–positive) treatment required**	*Perinatal or intrauterine death caused by anti-C and anti-Ce*
80	120†	24‡	64	25§	8‖	0

*Treatment: exchange transfusion and/or phototherapy.

†Fifty of the 120 were not detectable by an indirect antiglobulin test.

‡Twenty-two spontaneous or induced abortions, two fetal deaths unrelated to anti-C or anti-Ce. Both women had subsequent healthy surviving infants.

§One set of twins, 24 pregnancies.

‖One woman accounted for four of the eight babies.

An immediate double-volume exchange transfusion was carried out, followed by a second exchange transfusion on the second day of life. The highest indirect serum bilirubin level was 228 μmol/L (13.4 mg/dl). She had evidence of transient hepatocellular damage,[2,3] an index of severe hemolytic disease, with the direct (conjugated) bilirubin level peaking at 125 μmol/L. The neonatal nursery course was uneventful. At 7 months of age she was progressing normally.

Results

Prevalence of anti-C or anti-Ce alloimmunization. The Rh Laboratory records for the 28-year period, Nov. 1, 1962, to Oct. 31, 1990, were reviewed. The laboratory is responsible for antibody screening of all women in Manitoba (population of 1 million with 17,000 pregnancies annually). The policy of the laboratory is that all pregnant women should be screened at their first prenatal visit. Unimmunized Rh-negative women are then screened at monthly intervals. A second blood sample for screening of unimmunized Rh-positive women is requested at 28 to 34 weeks' gestation but is not always obtained.

Antibody screening of maternal serum is carried out by a sensitive two-stage, enzyme-treated red blood cell method[4] and a low-ionic autoanalyzer method.[5]

If an Rh-positive pregnant woman has a blood group alloantibody, further blood samples are requested at 2- to 8-week intervals, depending on length of gestation, the specificity of the antibody, and its strength (titer). If the antibody is one that is known to cause fetal hemolytic disease, amniotic fluid spectrophotometry or, in the past 5 years, fetal blood sampling is carried out, on the basis of the same criteria used for initiating either procedure in Rh-negative, Rh_o (D)–immunized pregnant women (history of a prior perinatal death, a fetus or infant requiring treatment, or antibody titers of ≥16 in albumin or ≥32 to 64 by indirect antiglobulin).[6]

Because the Rh Laboratory carries out all cord blood testing and treatment of affected babies after birth and, in conjunction with the Division of Fetal and Maternal Medicine, carries out all amniotic fluid measurements, fetal blood testing, and fetal transfusions in Manitoba, the subsequent course of each pregnancy and the fetal-neonatal outcome are known and are part of each alloimmunized woman's Rh Laboratory record.

The numbers of anti-C or anti-Ce alloimmunized pregnancies, excluding those in Rh-negative women with anti-D, for the 28-year period ending Oct. 31, 1990, are set out in Table I, with their respective outcomes. There were 80 C- or Ce-alloimmunized women who had 120 pregnancies (121 conceptuses) in the 28-year period. Nineteen women, six of whom were Native Americans, had 59 of the pregnancies (60 conceptuses). Of the remaining 61 women who had one C- or Ce-alloimmunized pregnancy, only three were Native Americans.

There were 22 abortions and two fetal deaths unrelated to C or Ce alloimmunization in the study group. Of the remaining 96 cases, 33 fetuses of 32 pregnancies (27.5%) were affected. However, only eight fetuses (6.7%) required treatment after birth: Two needed exchange transfusions and six required only phototherapy. Two of the six subsequently required simple transfusions.

All eight treated babies were only moderately affected. None required induced early delivery and none required intrauterine fetal transfusion. In this series there were no deaths caused by C or Ce alloimmunization. One woman, a Native American, accounted for four of the eight babies who needed treatment (one required exchange transfusion and the other three required phototherapy only). Her next baby, again affected, did not need treatment. In all, she accounted for seven of the 120 C- or Ce-alloimmunized pregnancies.

Some Manitoban C-alloimmunized women had anti-C or anti-Ce antibody titers as high as that of our patient (256 in albumin, 1 in saline solution). Five women with affected babies who required treatment had anti-C titers of 128 in albumin and 8 in saline solution, 64 in albumin and 8 in saline solution, 64 in albumin and 32 in saline solution, 16 in albumin and 16 in saline so-

lution, and 8 in albumin and 0 in saline solution, respectively. Three women who had mildly affected babies not requiring treatment had anti-C titers of 2048 in albumin and 512 in saline solution, 256 in albumin and 16 in saline solution, and 256 in albumin and 8 in saline solution, respectively.

Literature survey. The literature relating to anti-C or anti-Ce alloimmunization was surveyed from 1944 to 1990 (*Quarterly Cumulative Index Medicus*, 1944 to 1956; *Current List of Medical Literature*, 1950 to 1959; and *Cumulated Index Medicus*, 1960 to 1990). Although the review of the non-English literature was thorough, it may not have been complete; the review of the English literature was comprehensive.

Perinatal deaths from anti-C or anti-Ce hemolytic disease. Reports of perinatal deaths or fetuses requiring transfusions for anti-C or anti-Ce hemolytic disease are extremely rare. In 1981 Baker et al.[7] reported on a group A, Rh-positive, C-negative woman in whom anti-C developed as a result of blood transfusion in childhood. Her first affected baby required phototherapy. Her second pregnancy ended at 39 weeks' gestation in a macerated stillbirth. There was autopsy evidence of erythroblastosis. The anti-C titer at that time was 1024 in albumin. At the beginning of her third pregnancy, the anti-C titer was 512 in albumin. Because of amniotic fluid bilirubin levels of 4.8 and 6.0 μmol/L at 27 and 29 weeks' gestation, three intraperitoneal fetal transfusions were carried out (90, 110, and 130 ml of C-negative compatible blood at 30, 32, and 34 weeks' gestation). The infant, delivered at 36 weeks' gestation, had a cord hemoglobin concentration of 162 gm/L (65 gm/L of which was residual fetal C positive in origin). He did well after phototherapy and one exchange transfusion.

Hardy and Napier[8] in their review of red blood cell antibodies in Rh-positive women in south and mid Wales over a 30-year period (1948 to 1978) described two infants with hemolytic disease caused by anti-C who died, one after an exchange transfusion and one without undergoing exchange transfusion. They gave no further details of these two cases. Clarke et al.[9] in their report of deaths from hemolytic disease in England and Wales in 1984 and 1985 report, without giving any details, one perinatal death from C hemolytic disease in the 9-year period from 1977 to 1985. It is quite possible

that the perinatal death reported by Clarke et al. is one of the deaths reported by Hardy and Napier.

Remaining case reports. All remaining case reports of anti-C or anti-Ce alloimmunization[10-17] described affected infants who did not require treatment or who needed only exchange transfusion or phototherapy. None were severely affected, other than that of Waller et al.[10] (1944). This, the first reported example of hemolytic disease caused by anti-C, was a baby born at 39 weeks' gestation who had moderately severe hemolytic disease and required seven simple transfusions. The syndrome of transient hepatocellular damage developed in the baby, but it recovered with no neurologic sequelae.

Atypical or irregular blood group antibody surveys. Various surveys of the prevalence of non–Rh_o (D) blood group alloimmunization, including anti-C and anti-Ce, have been published[8,9,18-25] (Table II). The prevalence of anti-C and anti-Ce alloimunization ranged from 8.7[8] to 185[20] per 100,000 pregnancies. In the current series the prevalence was 25.3 per 100,000 pregnant women (Table II).

The numbers of affected babies requiring treatment in all of the series reporting affected babies needing treatment totaled 15, eight of them in our series. The incidence of affected babies requiring treatment compared with the total number of anti-C and anti-Ce alloimmunized pregnancies ranged from 2.6% to 22.2% (5.7% in our series).

Comment

Anti-C, Ce alloimmunization occurs rarely and when it does occur does not often cause serious hemolytic disease. The reported prevalence of C and Ce alloimmunization in unselected pregnant populations ranges from 8.7 to 13.6 per 100,000 pregnancies, except in the series of Queenan et al.[20] and our series. We have no explanation for the extremely high prevalence of C alloimmunization in the series of Queenan et al. (185/100,000). The reasons for the increased prevalence in our series are twofold. First, a sensitive two-stage, enzyme-treated red blood cell screening method was used.[4] Forty-two percent of our C or Ce alloimmunized population had antibodies detected only by this method and not by indirect antiglobulin.[6] If indirect antiglobulin screening alone had been used, which may well have been the case in the other series, the prevalence of C or Ce alloimmunization in our series would have been 14.7 per 100,000 pregnancies. Second, the prevalence of anti-C or anti-Ce in Manitoban women has an overrepresentation of Native Americans, six of 19 such women (32%) accounting for 25 of the 59 multiple alloimmunized pregnancies (42%). There is no such overrepresentation in the 61 women who had only one C or Ce alloimmunized pregnancy (3 or 5%). If one corrects for the multiparity of Manitoban Native American C and Ce alloimmunized women, the prevalence of C or Ce alloimmunization becomes 12.2 per 100,000 pregnancies, well within the 8.7 to 13.6 per 100,000 pregnancies reported by others.

Although anti-C or anti-Ce alloimmunization very rarely causes perinatal deaths (four or five in all reported series in the past 46 years), it does so on occasion. We believe that the C or Ce alloimmunized pregnant woman should be managed in the same manner as the D, c, or Kell alloimmunized pregnant woman. It would appear from the case of Baker et al.[7] and our case that blood transfusion causing C alloimmunization is a significant risk factor.

From the standpoint of the critical anti-C or anti-Ce antibody titer at which invasive, investigative procedures such as amniocentesis or cord blood sampling should be carried out, our patient had a titer of 256 in albumin. The patient of Baker et al.[7] had a titer of 512 in albumin. These titers are considerably higher than the critical anti-D titers for similar investigations. Several of our patients with mildly or moderately affected babies had similar or even higher antibody titers, although most had greater immunoglobulin M (saline solution) components. However, because one of the women had an affected baby who required treatment in spite of a titer of 16 in albumin and 16 in saline solution and another had a titer of only 8 in albumin and 0 in saline solution, we recommend that the same titer criteria for invasive investigations in C or Ce alloimmunized pregnancies as in D alloimmunized pregnancies should be used, $\geq$16 in albumin and $\geq$32 to 64 by indirect immunoglobulin.

An integrated therapy for peripartum pelvic instability: A study of the biomechanical effects of pelvic belts

Andry Vleeming, PhD,[a] H. Muzaffer Buyruk, MD,[c] Rob Stoeckart, PhD,[a] Sacid Karamursel, MD,[c] and Chris J. Snijders, PhD[b]

Rotterdam, The Netherlands, and Istanbul, Turkey

OBJECTIVES: The objectives of this study were to investigate the influence of pelvic belts on the stability of the pelvis and to discuss the treatment of peripartum pelvic instability.
STUDY DESIGN: In six human pelvis-spine preparations, sagittal rotation in the sacroiliac joints was induced by bidirectional forces directed at the acetabula. Weight-bearing was mimicked by the application of a compressive force to the spine. The biomechanical effect of a pelvic belt was measured in 12 sacroiliac joints.
RESULTS: The pelvic belt caused a significant decrease in the sagittal rotation in the sacroiliac joints. The effect of a 100 N belt did not differ significantly from that of a 50 N belt.
CONCLUSION: The combination of a pelvic belt and muscle training enhances pelvic stability. The load of the belt can be relatively small; location is more important. The risk of symphysiodesis, especially as a result of the insertion of bone grafts, is emphasized. (Am J Obstet Gynecol 1992;166:1243-7.)

Key words: Pelvic instability, low back pain, sacroiliac joint, symphysiolysis, symphysiodesis

The pelvis must be considered part of a complex kinematic chain between the legs and spine. Important connections in this chain are the joints between the sacrum and the L-5 (intervertebral disc and zygapophyseal joints) and the sacroiliac joints. Several studies demonstrate mobility in the sacroiliac joints.[1-5] Profound effects on the kinematic performance of the spine result from exceptional laxity of the sacroiliac

joints, from which dysfunction of the low back, pelvis, and hip joints may occur.[5]

The reported incidence of pelvic instability, which is inadequately characterized, varies from 0.005% to 4%.[6, 7] This lack of characterization may be related to the lack of agreement for criteria that differentiate between normal and pathologic peripartum relaxation.[8]

Since 1930, a radiologic method has been used to diagnose pelvic instability.[9] However, because most symphyseal joints show peripartum diastasis, radiographs are of little value.[3, 10] Callahan[8] stated that without clinical findings even a 3 to 5 cm separation cannot be considered a rupture of the symphysis in the absence of clinical symptoms. Clinical evaluation seems to be the only method by which to discover whether symphyseal diastasis creates symptoms.

In most studies on pelvic instability, limited attention is given to the functional anatomic interaction of the constituent parts. Pelvic instability defined according to topographic anatomy can be viewed as abnormal displacement of the pubic bones and treated as an isolated problem. In that case it is easy to forget that hypermobility at the symphysis is exclusively possible with hypermobility in the sacroiliac joint and/or profound bone deformation. Although bone deformation cannot be disregarded, extensive deformation is not usual (Vleeming A, et al. Unpublished observations). Therefore hypermobility of the symphysis is accompanied by hypermobility in the sacroiliac joints.

One of the structural devices causing stability in the sacroiliac joints, as well as in other joints, is the shape of the articular surface. Recently, Vleeming et al.[11] demonstrated specific roughening patterns in the sacroiliac joints that were more pronounced in men than in women. As shown in a biomechanical study,[12] articular surfaces with roughening patterns show higher friction coefficients. Roughening of the sacroiliac joints, which increases stability, was considered to be a physiologic process that reflected dynamic development. With reference to a loading mode in the frontal plane, friction in the sacroiliac joints could theoretically be increased by the use of a pelvic belt.[12] In that biomechanical model the location of the belt, and not the load, appeared to be crucial.

The use of pelvic belts in peripartum women has been demonstrated by Snijders et al.[13] Furthermore strapping of the pelvis gave satisfactory results in cases of symphysiolysis.[14-17] However, there is no experimental evidence that shows how strapping of the pelvis is effectively performed; the specific biomechanical effects are also obscure. In this study the influence of pelvic belts on the stability of the pelvis has been evaluated by measuring the effect of the belt on sagittal rotation (nutation and contranutation) in sacroiliac joints of human pelvis-spine preparations. The requested precision of the measurements cannot be obtained in living persons unless invasive techniques are used.

Material and methods

Six human specimens were embalmed by vascular perfusion with a medium containing 2.2% formaldehyde. Four of the specimens (P2, P3, P4, and P5) were female (age range 83 to 97 years). The ages of the male specimens (P1 and P6) were 76 and 90 years, respectively. The fifth lumbar vertebra of each specimen was connected to a frame. To mimic a real-life situation, an artificial gravity force was applied to the pelvis (for details, see Vleeming et al.[18]). Bilateral forces of 150 N were applied to the acetabula of the iliac bones to induce movement in the sacroiliac joints. To induce nutation (flexion) and contranutation (extension), cranioventral and dorsal forces, respectively, were used. Sagittal movement between ilium and sacrum was recorded by digital displacement meters. Movement was measured with and without a pelvic belt. For this purpose a 110 × 5 × 0.3 cm leather pelvic belt was positioned just above the greater trochanter. The tension and the size of the belt could be tightened with adjustable hooks and a steelyard.

Movement in each of the 12 sacroiliac joints was tested at four subsequent stages: without belt, with a pelvic belt of 50 N tension, with a belt of 100 N tension, and without belt. Stage 4 served to control whether the sacroiliac joints remained intact during the experiment.

The amount of rotation was recorded during the first, fifth, and tenth minutes of force. The measurements at 1 and 5 minutes were used to control whether displacement occurred regularly. Normally, about 90% of total rotation occurred during the first minute. The measurements of the tenth minute (generally three measurements for each joint at each stage) were used to calculate the amount of rotation between sacrum and ilium. For the method of calculating total rotation (nutation plus contranutation), see Vleeming et al.[18] For each joint the significance of the differences between the stages of the experiment was tested with the Student t test; for all joints as a group the sign test was used ($p \leq 0.05$ for both). Because no significant differences occurred between the measurements of stage 1 and stage 4, those data were grouped and used as controls.

Results

Without a pelvic belt, the total rotation (nutation plus contranutation) in the sacroiliac joints varied between 0.12 and 4.54 degrees (Fig. 1). In seven out of 12 sacroiliac joints, application of the 50 N loaded pelvic belt caused a significant decrease in rotation. In these preparations the average reduction in rotation was 29.3% For all preparations together rotation was significantly

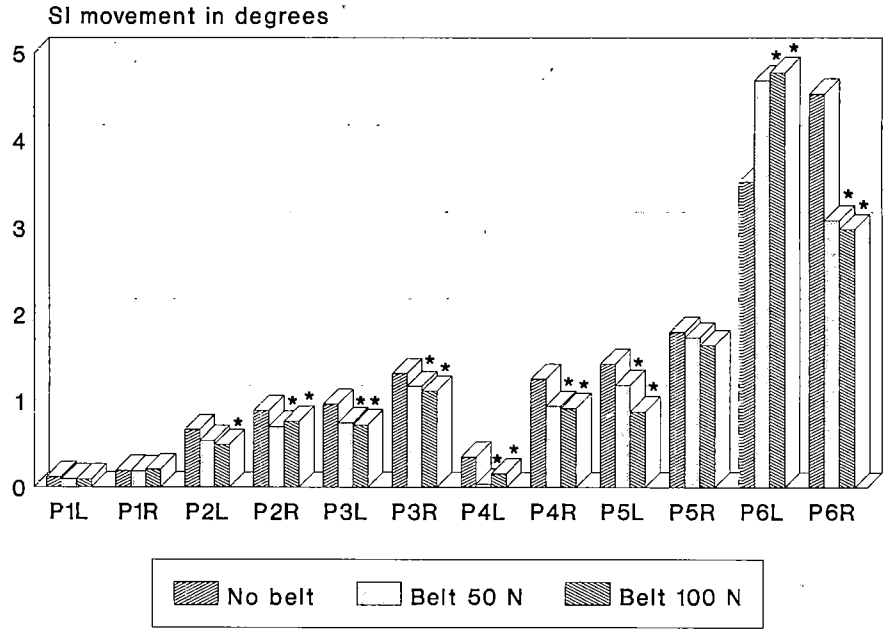

Fig. 1. Effect of application of 50 and a 100 N pelvic belts on sagittal rotation in 12 sacroiliac *(SI)* joints (*L*, left; *R*, right). *Asterisk*, Significant difference from control.

reduced by 18.8%. A comparable result was obtained with the 100 N belt: a significant decrease in eight sacroiliac joints and 29.5% and 18.5% reductions, respectively. Again, the reduction in rotation was statistically significant. The differences between the 50 and 100 N belts were not statistically significant.

The belt failed to reduce rotation in four sacroiliac joints, three of which were in male pelvises. One of these joints (pelvis 6, left), showed a significant increase in rotation.

Comment

Specific comment. In this study the effect of a pelvic belt on sagittal plane movements was studied in 12 sacroiliac joints. Movement was significantly restricted by application of a nonelastic belt with a tension of 50 N. Larger forces did not give better results; this was also the case in the previously mentioned biomechanical model,[12] in which the efficacy of a pelvic belt was primarily determined not by the amount of tension but by the site of application. Wearing the belt just above the greater trochanter achieved self-bracing of the pelvis. Increase of force in this instance may even be counterproductive because the symphysis is artificially compressed.

In one joint of a male specimen, rotation in the sacroiliac joints was increased by the belt. This reversed effect may reflect degeneration of the joint or damage to the sacroiliac joint by disintegration of ridges and depression.[11] Motion in the sacroiliac joints of female subjects was decreased by the belt. This decreased motion may be related to the relatively low friction in female sacroiliac joints that results from their relatively small and flat articular surfaces,[11] which, when combined with hormonal weakening of the pelvic ligaments, may result in unstable pelvic joints during pregnancy. Initiating higher friction by means of a pelvic belt can enhance stability of the sacroiliac joints and the symphysis. Then less force in the ligaments is needed for bearing the upper body.[12]

Hypermobility at the symphysis needs hypermobility in the sacroiliac joints. However, exceptions may occur. There is evidence that relaxin stimulates metabolic processes in both the symphysis and the sacroiliac joints,[17, 19] but in peripartum symphyses its effect differs markedly.[20] Whether the mobilizing effect of relaxin on the symphysis is in concert with the relaxation of the sacroiliac joints is unknown. As a consequence, relaxin could be responsible for the unbalanced relaxation of the sacroiliac joints and symphysis, which could result in isolated symphyseal or sacroiliac joint problems.

General comment. Symphysiolysis is frequently the diagnosis in cases of pelvic instability. Objective criteria are generally lacking. That diagnosis is often followed by treatment primarily directed at the symphysis, which may be assumed to be the site of the instability. However, this approach might preclude appropriate treatment. In the preparations studied an artificial separation of the pubic bones at the symphysis did not generate a massive loss of pelvic stability (Vleeming A, et al. Unpublished observations). These findings agree with those of Van Roosmalen.[21] These studies dem-

onstrate that true pelvic instability is characterized by simultaneous slackening of the dorsal sacroiliac joint ligaments and relaxation of the symphysis.

In a characteristic hospital report on symphysiodesis, the orthopedic surgeon stated, "A bone graft was inserted under strain in the symphysis." Insertion of bone grafts into the symphysis under strain as a treament for pelvic instability will lead to tension in the thin ventral sacroiliac ligaments and slackening of the dorsal interosseous sacroiliac joint ligaments, which will have serious consequences because the dorsal ligaments are extremely thick and are important to the stability of the sacroiliac joints.

If bone growth of the graft is achieved, another problem arises. The individual pelvic bones will be immobilized and will function as one massive bone with respect to the sacrum and vice versa. Increased hypermobility at the sacroiliac joints could result. Hypermobile sacroiliac joints imply large forces at the pubic bones. Thus insertion of bone grafts (especially under tension) into the symphysis may be counterproductive to a normal pelvis-spine mechanism. As Lavignolle et al.[3] demonstrated, the instantaneous center of rotation of the constituent bones of the pelvis is located at the symphysis. An appropriate functioning pubic articulation at the symphysis is therefore imperative for normal pelvic function.

Surgical symphysiodesis is based primarily on a study by Olerud and Walheim.[22] However, their relatively positive results may be partially the result of arthrodesis of the sacroiliac joints: Five of eight patients evaluated received both symphysiodesis and arthrodesis of the sacroiliac joints! Thus we question whether symphysiodesis is an appropriate treatment for pelvic instability, especially when bone grafts are used, because that approach disregards two facts: Nature created mobility between the pubic bones of men and women, and encroaching on the kinematic chain must have consequences elsewhere.

We concluded that a pelvic belt enhances pelvic stability because it reduces movement in the sacroiliac joints. If pelvic instability occurs, clinical tests can indicate whether problems are primarily at the sacroiliac joint, the symphysis, or both. Determination of the amount of instability in relation to pain seems to be crucial. Immediately after the initial functional test, the test procedure can be repeated with a pelvic belt, which can be initially positioned just above the greater trochanter. The exact position must be adjusted according to the patient's demands. If pain is diminished, therapeutic application of a pelvic belt is advisable; this supports the beneficial results of strapping the pelvis as described by several authors.[8, 14-17] In severe cases strapping can be combined with bed rest.[14, 15] If hypermobility at the symphysis occurs, the lithotomy position with strongly abducted legs must be used cautiously because of the adductor muscle stress on the symphysis.[15, 23, 24]

We do not advise use of the pelvic belts as a monotherapy. In our opinion simultaneous muscle training, especially training of the internal pelvic musculature and the gluteus maximus muscle, is important. This approach is based on a biomechanical study[12] and on the consideration that the sacrotuberous ligaments are important structures in the kinematic chain between the pelvis and spine. Muscles attached to these ligaments, such as the gluteus maximus and in some individuals the long head of the biceps femoris, can dynamically influence movement in the sacroiliac joints. The gluteus maximus in particular can enlarge friction in these joints and thus can stabilize the pelvis.[25] If the proposed integrated approach is not efficient, then an increase of belt tension is not recommended.

If none of these interventions gives beneficial results, a surgical approach can be considered: arthrodesis of the sacroiliac joints if the sacroiliac joints are exceptionally unstable and symphysiodesis if symptoms are located predominantly at the symphysis. In the latter case the two-hole plate technique described by Webb et al.[26] seems to be appropriate from a functional anatomic and biomechanical point of view.

We thank Mr. J. G. Velkers, Mr. C. A. C. Entius, Mr. J. P. van Wingerden, Ms. C. E. S. Brisland, Dr. F. K. Lotgering, Dr. T. Stijnen, and Ms. I. Burggraaf for their assistance.

Giant ovarian cyst: Case report

Miguel Zamora-Garza, MD, Joel Rizo, MD, and Alberto Dominguez, MD
Mexico City, Mexico

We present the case of a woman 22 years old with an ovarian cyst of 6 years' duration. The total weight of the tumor was 154 pounds (70 kg). She was treated surgically with good results. (Am J Obstet Gynecol 1992;166:1247-8.)

Key word: Giant ovarian cyst

We describe a case of a 22-year-old woman with an ovarian cyst of 6 years' duration weighing 154 pounds.

Case report

Clinical history. The patient was a 22-year-old woman admitted to the Woman's Hospital (Health Department) on Nov. 21, 1988. She came from a town in the state of Oaxaca, México.

She presented with features of social deprivation. She was unmarried, with unknown parents and four brothers who died of unknown causes.

At age 13 menstrual periods started; they occurred every 30 days and lasted 3 days. There had been no sexual activity. Her last menstruation was on April 12, 1988. At the age of 16, she noticed that her abdomen was growing gradually, and it was painful.

In 1985 she was hospitalized and nonspecific tests including an abdominal puncture were done. Results are unknown.

The patient reported that since January 1988 the large abdominal volume had made her lose her equilibrium. She had also lost the use of muscles and was fatigued by small efforts. She had had amenorrhea for 17 months, and she had edema of the lower extremities.

Physical examination. Weight on admission was 242 pounds, heart rate 88 beats/min, respiratory rate 24 breaths/min, temperature 36° C, and arterial pressure 110/70 mm Hg. She appeared older than her age with bad conformation because of the large volume of the abdomen. She was pale, with normal breasts and a small amount of pubic hair. The abdomen demonstrated collateral venous trajectories. The measurement from the pubis to the top of cyst was 128 cm. No visceral growth was found. Peristalsis was present. A pelvic examination was not done. The sphincter tonus was normal, and we could not feel either the uterus or the adnexae by rectal

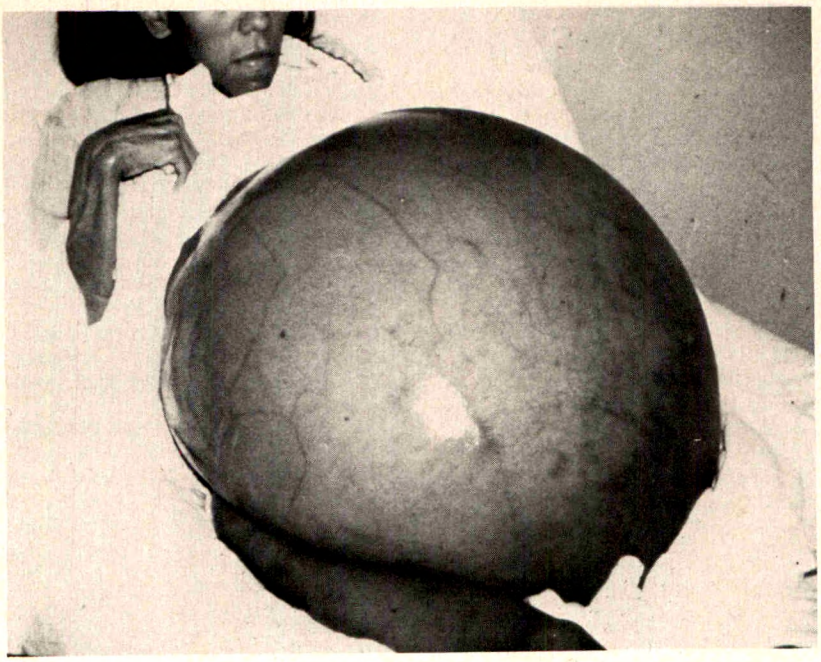

Fig. 1. Appearance of the patient on admission.

examination. The lower extremities had bimalleolar edema, loss of muscular volume, and atrophic changes of the skin (Fig. 1).

On Nov. 23, 1988, she had a cough with basal rales that made pulmonary ventilation very difficult. The cardiac rate increased to 110 beats/min. There was moderate obstruction and hypoxemia with a tendency to hyperventilation. The electrocardiogram showed a sinus tachycardia.

Renal ultrasonography showed hydronephrosis of the right kidney and moderate cholestasis in the left kidney.

The pulmonary surface was diminished on x-ray film. The right hemidiaphragm was at the level of the fourth space between the ribs and the left hemidiaphragm was at the seventh space. The cardiac shadow was horizontal.

The abdominal x-ray films and the abdominal sonogram could not be interpreted.

Treatment with digitalis and decompressive paracentesis was undertaken for 7 days with extraction of 28.8 L of fluid weighing 71.9 pounds. The fluid was negative for malignant cells.

The patient's condition improved, and we decided to perform an exploratory laparotomy on Dec. 5, 1988, with a preoperative diagnosis of a giant ovarian tumor.

Operative procedure. With the patient under general anesthesia, the abdomen was opened. A tumor of the right ovary was removed with an intraoperative diagnosis of serous cystadenoma. The rest of the structures were normal. The abdominal wall was closed with the Mayo technique. During the operation the patient received 400 ml of blood, 250 ml of plasma, and 200 ml of solutions. The postoperative course was satisfactory.

The patient's preoperative admission weight was 242 pounds (110 kg). Her postoperative weight was 88 pounds (40 kg). The weight of the tumor was 154 pounds (70 kg). After 36 days of hospitalization, her weight was 105.6 pounds (48 kg).

Comment

The patient was slowly decompressed because of the systemic effect of the tumor on the cardiovascular system. Fisher[1] reported dissemination after a puncture in the presence of a malignancy. In other reports it is suggested that the puncture is used to prevent rupture of the capsule and greater dissemination.[2]

There is little experience in cases of giant ovarian tumors. The participation of several specialties is necessary: gynecology, anesthesiology, critical care, rehabilitation, and histopathology. The more frequent complications mentioned in the literature are bleeding, supine hypotension, anesthesia complications, and splenic shock.

The blood pressure response to infusions of angiotensin II during normal pregnancy: Relation to plasma angiotensin II concentration, serum progesterone level, and mean platelet volume

Masaharu Ito, MD, Toshimitsu Nakamura, MD, Toshihiro Yoshimura, MD, Hideki Koyama, MD, and Hitoshi Okamura, MD

Kumamoto, Japan

OBJECTIVE: This study is a survey of the determinants of refractoriness to the pressor effects of angiotensin II during normal pregnancy.

STUDY DESIGN: In 25 normal pregnant women, the effective angiotensin II pressor dose was determined 88 times from the twenty-fifth to the thirty-second week of gestation. Immediately before the angiotensin II infusion, blood samples were collected and measured for plasma angiotensin II concentration, serum progesterone level, platelet count, and mean platelet volume.

RESULTS: The effective pressor dose had a significantly positive correlation with plasma angiotensin II concentration and serum progesterone level and a negative correlation with mean platelet volume.

CONCLUSION: The pregnancy-associated refractoriness to angiotensin II is physiologically determined, at least in part, by the elevated circulating levels of endogenously produced angiotensin II and by the progesterone produced by the placenta, whereas platelet activation attenuates the relative refractoriness during normal pregnancy. (Am J Obstet Gynecol 1992;166:1249-53.)

Key words: Effective pressor dose, angiotensin II, progesterone, platelets, normal pregnancy

Pregnant women are relatively refractory to the pressor effects of angiotensin II. In contrast, women who later have the development of preeclampsia lose the normal gestational resistance to the pressor effects of angiotensin II by the twenty-sixth week of gestation.[1] Thus far, volume deficit, plasma angiotensin II level, 5α-pregnane-3,20-dione, and thromboxane A_2 synthetase inhibitors are known to affect the pregnancy-associated refractoriness to the pressor effects of angiotensin II.[2-4] In normal pregnancy, the increased thromboxane biosynthesis is mainly platelet derived and is consistent with increased platelet activation.[5] Young platelets are large, and they become progressively smaller with age.[6] This condition requires much research, particularly with regard to the mean platelet volume and the pressor effect of angiotensin II.

We simultaneously determined the effective angiotensin II pressor dose, plasma angiotensin II concentration, serum progesterone level, platelet count, and mean platelet volume to survey the determinants of refractoriness to the pressor effects of angiotensin II during normal pregnancy and the interrelationships between the effective pressor dose and these parameters.

Material and methods

Twenty-five pregnant women with single fetuses were studied. These women were managed at Kumamoto University Hospital. Full and informed written consent was obtained from the subjects for their participation. None showed symptoms or signs of preeclampsia on the first visit to the clinic, and none had a history of renal disease or a personal or family history of hypertension. The mean age of the subjects was 29.6 years (range 23 to 42 years). There were 8 primigravid and 17 multiparous subjects. In all cases gestational age was estimated from the date of the last menstrual period, and ultrasonographic measurements of the gestational sac and the crown-rump length were used to confirm the gestational age until the twelfth week of pregnancy. These patients were seen throughout the course of pregnancy at 1- or 2-week intervals and were managed with routine monitoring according to the pro-

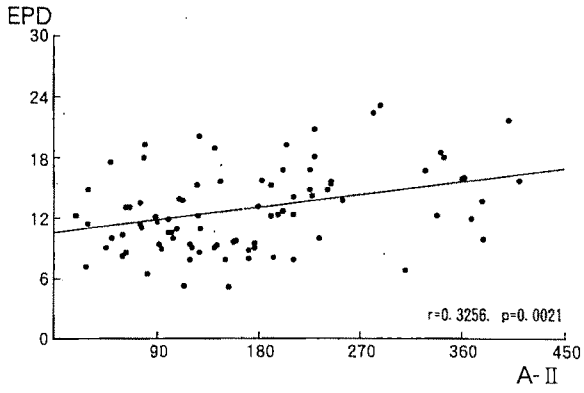

Fig. 1. Relationship between effective pressor dose and plasma angiotensin II concentrations during normal pregnancy. Effective pressor dose was significantly correlated with plasma angiotensin II concentration ($r = 0.3256$, $n = 87$, $p = 0.0021$).

tocol for the hospital, which consists of blood pressure monitoring, urinalysis for protein, body weight, and uterine fundal height measurements, and ultrasonographic measurement of fetal development. No subjects had taken aspirin, other salicylates, or nonsteroidal antiinflammatory medications for a period of 30 days before the study, and their diets were unrestricted during pregnancy.

In all studies the dose of angiotensin II required to elicit a pressor response was determined as described by Gant et al.[1] In 25 subjects the effective pressor dose was determined 88 times between the twenty-fifth and thirty-second week of gestation. The mean number of angiotensin II infusions to each patient was 3.75 ± 0.5 (range 3 to 4). The interval from one angiotensin II infusion to the next was at least 2 weeks. The patients were placed in the supine position and were tilted about 15 degrees to avoid hypotensive supine syndrome. The patients remained in this position for 20 minutes to stabilize the circulation before the angiotensin II infusion was begun. The blood pressure cuff was applied to the right upper arm. A mercury sphygmomanometer was used to measure blood pressure. The diastolic blood pressure was estimated from the fifth Korotkoff sound. After the diastolic blood pressure had stabilized, an intravenous infusion containing 1 μg of angiotensin II amide (Hypertensin Ciba, Ciba-Geigy, Ltd., Basel) per milliliter of 5% dextrose in water was given with an infusion pump (Ivac 530, Ivac Corp., San Diego). The initial dosage (<5 ng/kg of maternal weight per minute) was infused, and small progressive increments were given every 5 minutes until the diastolic blood pressure increased by 20 mm Hg over the baseline diastolic blood pressure. The minimum amount of angiotensin II amide infused per kilogram of body weight per minute that caused an increase in diastolic blood pressure of 20 mm Hg was defined as the effective pressor dose. A nonstress test was performed during each angiotensin II infusion. All patients underwent follow-up throughout pregnancy until at least 4 weeks post partum. None showed any symptoms or signs of preeclampsia.

Immediately before the angiotensin II infusion, blood samples were collected by right antecubital venipuncture for determination of the plasma angiotensin II concentration, serum progesterone levels, platelet count, and mean platelet volume. After plasma or serum was separated by centrifugation, the assay samples were stored at −20° C until they were analyzed. The plasma angiotensin II concentration and serum progesterone levels were assayed with a commercially available radioimmunoassay kit (angiotensin II kit, SMI Bristol Co., Sagamihara, Japan; DPC progesterone kit, Diagnostic Products Co., Los Angeles). All samples were assayed in duplicate. The intraassay and interassay coefficients of variation were 3.2% and 8.4% for plasma angiotensin II determinations and 6.6% and 9.3% for serum progesterone determinations, respectively. Analyses of platelet count and mean platelet volume were performed on a Coulter Counter (model S-plus II, Coulter Electronics Ltd., Luton, United Kingdom), which was an automated hematologic analyzer. Platelet counts were estimated by differential gating, mean platelet volume was measured in femtoliters.[7] Channel calibration with latex particles (platelet volume calibration latex, model No. 8.6 H; Coulter) was completed daily and later weekly to ensure sample comparability with respect to mean platelet volume and platelet distribution width values.

Data were expressed as mean ± SD. The number of samples at each time is indicated by n. Levels of significance were calculated with the unpaired Student t test. The correlation coefficient between a pair of parameters was calculated by single linear regression with a least-squares minimization equal weighting of data points. A p value <0.05 for the number of observations was considered significant.

Results

Effective pressor dose changes during pregnancy. The effective pressor doses at 25, 26, 27, 28, 29, 30, 31, and 32 weeks of gestation were 12.4 ± 2.7 ($n = 7$), 12.9 ± 3.9 ($n = 16$), 12.1 ± 3.2 ($n = 8$), 12.0 ± 4.2 ($n = 13$), 13.0 ± 3.1 ($n = 7$), 14.2 ± 5.2 ($n = 17$), 12.0 ± 3.1 ($n = 6$), and 13.1 ± 4.6 ($n = 14$) ng/kg/min, respectively. From the twenty-fifth to thirty-second week of gestation, the mean effective pressor dose ranged from 12.0 to 14.2 ng/kg/min, and the effective pressor dose was not significantly different from one gestational week to the next.

Correlations between effective pressor dose and plasma angiotensin II concentrations. The plasma angiotensin II concentrations at 25, 26, 27, 28, 29, 30, 31,

and 32 weeks of gestation were 138 ± 71 (n = 7), 124 ± 79 (n = 15), 137 ± 50 (n = 8), 195 ± 98 (n = 13), 212 ± 73 (n = 7), 178 ± 85 (n = 17), 183 ± 78 (n = 6), and 169 ± 89 (n = 14), pg/ml, respectively. The plasma angiotensin II concentration gradually increased and became stable by the twenty-ninth week of gestation. There was not a significant correlation between the plasma angiotensin II concentration and the gestational age (r = 0.1761, n = 87, p = 0.1027). In 25 normal pregnant women, however, a significant positive correlation was found between the effective pressor dose and the plasma angiotensin II concentrations (Fig. 1).

Correlations between effective pressor dose and serum progesterone level. The serum progesterone levels at 25, 26, 27, 28, 29, 30, 31, and 32 weeks of gestation were 63.6 ± 14.6 (n = 7), 63.8 ± 15.6 (n = 13), 67.6 ± 19.0 (n = 8), 67.8 ± 15.5 (n = 13), 70.1 ± 13.8 (n = 7), 92.4 ± 36.0 (n = 17), 106.8 ± 24.8 (n = 6), and 105.1 ± 38.2 (n = 15) ng/ml, respectively. The serum progesterone level gradually increased between the twenty-fifth and thirty-second week of gestation. There was a significant correlation between serum progesterone level and gestational age (r = 0.4774, n = 86, $p < 0.0001$). In 25 normal pregnant women a significant positive correlation was found between effective pressor dose and serum progesterone levels (Fig. 2).

Correlations between effective pressor dose and platelets. The platelet counts at 25, 26, 27, 28, 29, 30, 31, and 32 weeks of gestation were 215 ± 23 (n = 5), 228 ± 56 (n = 15), 224 ± 33 (n = 8), 237 ± 59 (n = 13), 229 ± 26 (n = 6), 246 ± 55 (n = 14), 219 ± 33 (n = 6), and 223 ± 53 (n = 12) $\times 10^3$/ml, respectively. The mean platelet volumes at the same weeks of gestation were 8.9 ± 0.7 (n = 5), 8.8 ± 1.0 (n = 16), 8.9 ± 1.0 (n = 8), 9.1 ± 0.8 (n = 13), 8.5 ± 0.7 (n = 6), 9.0 ± 0.9 (n = 14), 8.9 ± 1.3 (n = 6), and 9.4 ± 1.0 (n = 12) fl, respectively. In 25 normal pregnant women a significant negative correlation was found between the effective pressor dose and the mean platelet volume (Fig. 3), and a significant positive correlation was found between the effective pressor dose and platelet counts (r = 0.2405, n = 78, p = 0.0339). There was a marked negative correlation between the platelet counts and the mean platelet volume (r = −0.4578, n = 79, $p < 0.0001$).

Comment

Normal pregnant women are characterized by a relative refractoriness to angiotensin II.[8] In the study of Abdul-Karim and Assali[8] primigravid women, 21% of whom were white and 79% of whom were black, were studied sequentially from as early in gestation as possible throughout pregnancy. At early stages of pregnancy the mean effective pressor dose was 8.6 ± 0.8 ng/kg/min; this increased until the twenty-eighth week of gestation. From the twenty-sixth week until approximately the thirty-second week of gestation, the effective pressor dose remained markedly increased; the mean effective pressor dose ranged between 13.5 and 14.9 ng/kg/min.[1] In the current study the mean effective pressor dose remained between 12.0 and 14.2 ng/kg/min during this same gestational period. These changes in the effective pressor dose agree with findings reported by Gant et al.,[1,2] but the effective pressor dose values in our subjects were approximately 90% of the value they obtained in African-Americans.

The vascular sensitivity to infused angiotensin II may be dependent on racial or genetic differences. One third of the population in our study comprised multiparous women, and the age distribution was rather different from that in the study of Gant et al.[1,2] We previously reported that calcium supplementation could reduce the vascular sensitivity to infused angiotensin II.[9] Nutritional assessments of daily diet during

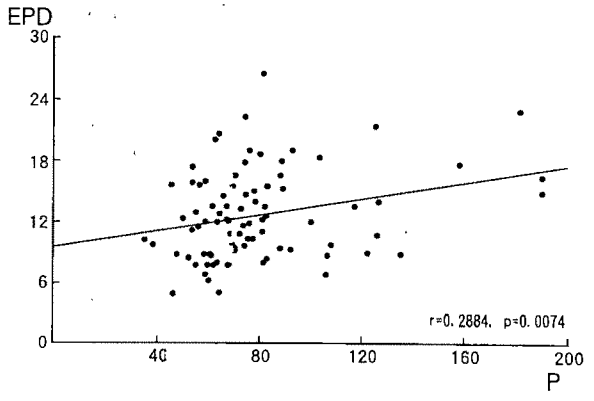

Fig. 2. Relationship between effective pressor dose and serum progesterone levels during normal pregnancy. Effective pressor dose was significantly correlated with serum progesterone level (r = 0.2884, n = 85, p = 0.0074).

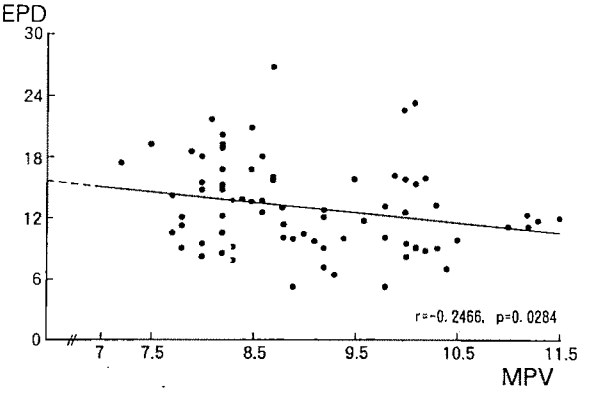

Fig. 3. Relationship between effective pressor dose and mean platelet volume during normal pregnancy. Effective pressor dose was significantly correlated with mean platelet volume (r = −0.2466, n = 79, p = 0.0284).

pregnancy revealed that pregnant Japanese women consume approximately 880 mg of calcium; this is a relatively low calcium intake. The low calcium intake during pregnancy may lead to the disparity noted between Japanese and African-Americans. With respect to the correlation between the effective pressor dose and other parameters of pregnancy, it is important to note that the effective pressor dose does not correlate significantly with gestational age. Maternal volume expansion, which can attenuate the pregnancy-associated refractoriness to angiontensin II has reached 40% in singleton pregnancies and is maintained at this level between the seventh and ninth months of pregnancy.[10] If the effective pressor dose value or blood volume expansion correlated significantly with gestational age, the evaluation of interrelationships between the effective pressor dose and other parameters that increase parallel to gestational age would have less significance because its statistical correlation is believed to be coincidental.

The renin-angiotensin-aldosterone system is remarkably altered in pregnant women. In normotensive pregnant women there are marked increases in the concentrations of plasma renin, renin activity, renin substrate, angiotensin II, and aldosterone. Angiotensin I is converted to the biologically active octapeptide angiotensin II by the converting enzyme. The conflict among studies of plasma angiotensin II concentration and our data in normal pregnancy is primarily a result of the heterogeneity of the study populations.[11] The major effect of angiotensin II is on peripheral vessel resistance. Angiotensin II depolarizes vascular smooth muscle and also has a contractile effect on vascular smooth muscle. There are two types of angiotensin II receptors in rat mesenteric artery, and their number is regulated by the circulating levels of angiotensin II. Prolonged exposure such as that which occurs in normal pregnancy, results in a time-dependent decrease in the binding capacity of the receptor with receptor degradation. Clark[12] reported that elevation of circulating angiotensin II levels selectively depresses the pressor response to exogenously administered angiotensin II and that the observed decrease in responsiveness to angiotensin II is not a result of a general hemodynamic mechanism but rather is specific for angiotensin II. A short-term blockade of endogenous angiotensin II formation by angiotensin-converting enzyme inhibitors produced a specific loss of pregnancy-associated refractoriness to angiotensin II.[13] Therefore the mean plasma angiotensin II concentration varies among individuals and with gestational age, and the interrelationships between the plasma angiotensin II concentrations and the effective pressor dose exhibited a weak (although significant) positive correlation. Thus endogenous angiotensin II may be one of the possible determinants of pregnancy-associated refractoriness to angiotensin II.

In preliminary studies Everett et al.[3] observed that the loss of refractoriness to the pressor effects of angiotensin II after delivery could be delayed by intramuscular administration of large amounts of progesterone to the mother during the later stages of labor, although intravenous administration of progesterone did not restore angiotensin II refractoriness. In an earlier study we found that the decrease in the pressor effects of angiotensin II in pregnant rats is mediated mainly by progesterone rather than by estrogen.[14] In this study a significant positive correlation was found between the effective pressor dose and the serum progesterone levels. The data obtained in the current study confirm those of our previous study. Interestingly, administration of 5α-pregnane-3,20-dione was associated with a blunting of the pressor response in late pregnancy.[3] The plasma concentrations of 5α-pregnane-3,20-dione are strikingly elevated during pregnancy, and this progestin is derived from A-ring reduction of progesterone in the liver. Progesterone decreases the concentration of angiotensin II receptors in rat uterine smooth muscle,[15] and it or a metabolite might have the same effect on vascular receptors in humans. Progesterone, in addition to endogenous angiotensin II, may be considered a possible determinant of the pregnancy-associated refractoriness to angiotensin II.

Pregnancy is accompanied by significant alterations in the hemostatic mechanism and its parameters. When subjects with normal pregnancy were compared with nonpregnant controls. O'Brien et al.[16] demonstrated a significantly lower platelet count and an increase in circulating platelet aggregation and in vitro hypoaggregability in the pregnant women. These findings suggest that normal pregnancy is associated with platelet activation, which leads to their in vivo clumping and aggregation. In this study neither the platelet count nor the mean platelet volume correlated significantly with gestational age. There was a striking negative correlation between the platelet count and the mean platelet volume. Young platelets are large, and they become progressively smaller with age.[6] In diseases characterized by a hyperdestruction and decreased life span of platelets, the platelet count decreases and the platelet volume increases.[17] The increase in mean platelet volume has been interpreted as evidence of increased platelet consumption and indicates shortened platelet life. From these findings it may be possible to show increased platelet consumption in normal pregnancy by demonstrating an increase in mean platelet volume even though the platelet count remains within the normal range. In this study a significant positive correlation was found between the effective pressor dose and the platelet count, and a significant negative correlation was

found between the effective pressor dose and the mean platelet volume. Intracellular platelet organelles are rich sources of β-thromboglobulin and 5-hydroxytryptamine. Arachidonic acid can be converted to thromboxane A_2 in platelets. Both thromboxane B_2 and 5-hydroxytryptamine are potent vasoconstrictors. The concentration of these compounds increases as a result of the release phenomenon after the activation of these platelets. Sakamoto,[18] who compared normal pregnant women with nonpregnant women, reported that β-thromboglobulin and a thromboxane A_2 metabolite (thromboxane B_2) increase significantly in plasma after the twenty-eighth week of pregnancy. Wilcox and Welch[4] reported that thromboxane A_2 synthetase inhibitor given for 3 days in anesthetized rats reduced basal thromboxane B_2 excretion by 75% and also attenuated the angiotensin II–induced rise in mean arterial blood pressure. These findings indicate that when such compounds are released from platelets, they may in part potentiate the pressor effects of angiotensin II that are associated with normal pregnancy.

In conclusion, the results of this study suggest that the pregnancy-associated refractoriness to angiotensin II is physiologically determined, at least in part, by the elevated circulating levels of endogenously produced angiotensin II and by the progesterone produced by the placenta, whereas the activation of platelets during normal pregnancy leads to attenuation of the relative refractoriness to angiotensin II. This observation is supported by the possibility that the impaired production of angiotensin II and progesterone during pregnancy and the increased destruction of platelets may lead to the loss of relative refractoriness to angiotensin II during pregnancy, such as that seen in pregnancy-induced hypertension.

A comprehensive program for cervical cancer detection and management

J.L. Benedet, MD, G.H. Anderson, MB, and J.P. Matisic, MD
Vancouver, British Columbia, Canada

OBJECTIVE: The purpose of this study was to document some of the results of a comprehensive provincial cytology and colposcopy program for the year 1988 and also to review the impact on the incidence and mortality rates for a clinical carcinoma of the cervix.
STUDY DESIGN: This study is a retrospective analysis of the cytologic results of all patients examined provincially in 1988 and a review of the clinical records of patients diagnosed with invasive cancer and those who died of disease.
RESULTS: In 1988 490,985 women (40% of all women over the age of 15 in the population) were screened, with 9.2% showing abnormal cells. A total of 79% of women screened were <50 years old and accounted for 86.3% of all abnormal smears. Women <35 years old were more likely than older women to have moderate dyskaryosis or worse.
CONCLUSION: Intensive comprehensive cytology and colposcopy programs reduce not only the incidence and mortality of clinical carcinoma of the cervix but also rates of in situ disease and other precursors. (AM J OBSTET GYNECOL 1992;166:1254-9.)

Key words: Cytologic screening, colposcopy, squamous carcinoma of the cervix

Regions or countries that embarked on comprehensive population-based cervical cancer screening programs in the past are now enjoying the benefits of these efforts as evidenced by a significant decrease in both the incidence and mortality rates for clinically invasive squamous cell carcinoma of the cervix.[1-6] In those areas where cytologic screening has not been as intense, clinical carcinoma of the cervix continues to be one of the most common forms of malignancy in women and a not infrequent cause of death. In British Columbia,[7] a cervical cancer screening program was introduced in 1949, which had as its main purpose the identification of the early stages in the natural history of the disease that was called preclinical carcinoma. Specifically, efforts were directed toward the detection and management of carcinoma in situ and microinvasive and occult invasive carcinoma. Cytologic smears suggesting earlier phases in the disease process (mild, moderate, and severe dysplasia) had cytologic follow-up. To achieve these aims, a centralized cytology laboratory was established to provide cytologic services for the entire population of the province.

Previous reports[8-12] have documented some of the activities and results of these programs. In the late 1960s and early 1970s, the disease rate for preclinical carcinoma in reproductive age women started to increase; this coincided with the establishment of the regional colposcopy clinic service to complement the existing cytology program.[13-15] The colposcopy clinics are hospital-based and staffed by community gynecologists. All information, results, and recommendations of the cytologic and colposcopic examinations for every patient are maintained in the central cytology registry.

The purpose of this report is to document some of the results of these programs for the year 1988 and to review the impact of these programs on the incidence and mortality rates for clinical carcinoma of the cervix and the trends that have been recorded for preinvasive neoplasia.

Table I. Cytologic screening in British Columbia, 1988

people. Approximately 2800 cervical cytologic smears per day are examined, and the records and results of each patient are incorporated into the computerized file in the central registry. This file now contains records on 1.5 million women. The file was used to produce cytologic data for all women who had a cervical smear in the calendar year January to December 1988. An analysis of these results by cytologic diagnosis and age group was then performed. The central file also contains information and results of all colposcopic examinations performed in the regional clinics. Data relating to all of the colposcopic examinations performed in 1988 were similarly abstracted and analyzed.

Results

During the year 1988, 490,985 women (40% of all women >15 years old in the population) had a cervical cytologic examination (Table I). Of these smears, 45,383 (9.2%) were reported as showing abnormal squamous cells. Squamous lesions consistent with moderate dysplasia or higher were present in 11,368 women. A total of 5576 smears were recorded as being unsatisfactory for interpretation.

Table II shows the number of women screened by age group, those who had their first smear performed in 1988, and the number and rates per 1000 women screened who had abnormal smears showing squamous atypia. The decision as to who enters the screening program and the frequency with which smears are done is made by the woman and her physician. The number of women screened in these various age groups reflects these decisions rather than the composition of the population. Of the women screened, 79% were under the age of 50 years; this group accounted for 86.3% of all abnormal smears during that year. Eleven percent of all women screened in 1988 had their first smear in that year and were responsible for 3862 (8.5%) of all abnormal smears. The proportion of first-time screened women was highest in those under the age of 20 years (52%), followed by women aged 20 to 34 years (11%), and those ≥65 years (11%). Age-specific rates for abnormal smears in women screened either for the first time or previously are also presented in Table II. In women previously screened, the rate decreased with advancing age. These trends are not entirely unexpected as if sufficient numbers of women in the younger age groups of a population are screened the rates of disease in those cohorts should fall over time.

Table III. Analysis of squamous atypia

Category	No.	%
Benign atypia	10,308	22.7
Mild dyskaryosis	23,707	52.2
Moderate dyskaryosis	8,399	18.5
Marked dyskaryosis	1,950	4.3
Suspicious	950	2.1
Malignant	69	0.2
TOTAL	45,383	100.0

Table III presents an analysis by cytologic abnormality for those 45,383 women found to have some form of squamous atypia on the Papanicolaou test. Approximately 75% of these individuals had cell changes consistent with benign atypia or mild dysplasia. This reflects the nature of the population screened, the majority having had several previous Papanicolaou smears. In a highly screened population, reexamination tends to result in lesions being diagnosed and managed at an earlier stage.

Table IV presents the percentage of the various cytologic abnormalities noted within each age group. Women <35 years old were twice as likely to have significant lesions (moderate dysplasia or higher) than were older women (31.5% vs 15.9%).

Table V presents each cytologic diagnosis broken down into the number and percentage of women in each category by age group. Women in the 20- to 34-year age group had the highest proportion of abnormal smears in each cytologic category, followed by women in the 35- to 49-year age group.

Table IV. Analysis of age group by degree of cytologic abnormality

Age group (yr)	Total abnormal (No.)	Cytologic diagnosis				
		Benign atypia (%)	Dyskaryosis			Suspicious/malignant (%)

Percentage screened		5		45		29		14		7	

During the period of the study, it was our policy to recommend colposcopic evaluation for all patients with marked dyskaryosis or higher on Papanicolaou smear. Colposcopic examination was also recommended in patients with two or more consecutive moderately dyskaryotic smears and in cases where mild dyskaryosis was noted over a 24-month period.

In 1988 the 22 regional colposcopic clinics recorded 12,426 patient visits for diagnosis, treatment, and follow-up. Of these, 5667 women were attending a colposcopy clinic for the first time. In addition, a further 3234 women returned for repeat examination. Abnormal cytologic smears were responsible for 85.1% of all new patient colposcopy visits. Table VI lists the presenting cytologic abnormality for those women who had a first colposcopic examination in 1988. Of these women 72.7% were referred because of moderate or higher dyskaryosis on cytologic smears. A total of 3326 (74.2%) of new patients referred because of cytologic abnormality were judged to have satisfactory colposcopic examination on the basis of visualization of both the entire squamocolumnar junction and the lesion margins.

The age distribution of those women having a colposcopic examination for the first time in 1988 is presented in Table VII; 68% were <35 years of age and 92.8% were ≤50 years of age. As might be expected, the rate of satisfactory examinations correlated with the ages of the patients, with young patients having a much higher rate of satisfactory examinations.

The histologic diagnoses of all patients seen in 1988 who had colposcopically directed biopsies are presented in Table VIII. Twenty-eight patients had invasive carcinoma.

Fig. 1 presents the changes in the incidence and mortality rates for clinical invasive squamous carcinoma of the cervix in British Columbia from 1955 to 1988. The rates have shown a gradual decrease from an initial incidence rate of 28.4 per 100,000 women and a mortality rate of 11.4 to the current figures of 4.2, a reduction of 85%, and 2.3, a reduction of 80%, respectively. In addition, the rate and number of in situ carcinomas diagnosed in the screened population have decreased in later years, particularly in the past decade in the younger age group.

Fig. 2 presents the number of cases of in situ squamous carcinoma diagnosed per year between 1955 and 1988. The increase in the first 20 years is due to enhanced efforts to expand the program, resulting in detection of disease in previously unscreened women, prevalence cases, and, to a much lesser extent, to the increase in the population. The marked increase be-

Table VI. Results of colposcopic examination in new patients, 1988: Cytologic diagnosis

	Benign atypia	*Dyskaryosis*			*Suspicious*	*Malignant*	*Total*
		Mild	*Moderate*	*Marked*			
No.	150	1028	1255	1255	568	53	4309
%	3.5	23.9	29.1	29.1	13.2	1.2	100

tween 1974 and 1979 corresponded to the time that the colposcopy program was established and reflects a marked increase in the incidence rate of in situ carcinoma in our population. The cytology screening program predicted 2200 cases of carcinoma in situ in 1979.

The rates of carcinoma in situ per 1000 women screened by age group for the past 9 years in 3-year intervals are presented in Fig. 3. Although the rate in women >40 years old has remained constant, younger women, particularly those in the 25- to 29-year age group, have shown a marked decrease. These trends have occurred because of the colposcopy program, which, over time, has resulted in more of the earlier lesions being diagnosed and treated.

In 1988 the average cost per smear was $6.80. This includes all laboratory costs and the salaries of medical, technical, and clerical staff. Physician office fees are not included in this amount. The colposcopy service in the regional clinics is funded on a sessional basis. A session is approximately 3½ hours in length, during which an average of 12 patients are seen. The actual number of patients seen per session in the various clinics ranged from 8 to 35 and was related to the size of the community served, frequency of clinics held, and number of support personnel available for the session. If all patients with mild dyskaryosis or higher grades of abnormality were to have colposcopy, as suggested by some authorities, a fourfold increase in sessional funding would be required. All medical and hospital costs are covered by universal government health insurance plans.

Comment

Preclinical cervical carcinoma is a condition that is well suited to early detection by a screening program. Although squamous carcinoma of the cervix is a common disease, it has a long preclinical phase so that intervention at this stage can influence the natural history of the disease to prevent progression from a preinvasive to an invasive carcinoma in the majority of instances.

Although much has been written and a great deal of knowledge accumulated with regard to the causes and epidemiologic features[16-21] of squamous neoplasia of the cervix, primary prevention to date has not been particularly effective. Most efforts with regard to the control of cervical cancer have been directed toward secondary prevention with cytologic smears in a screening program. The detection of early preclinical invasive cancer, known as microinvasive or occult invasive carcinoma, in addition to the detection of intraepithelial forms of the disease, is also desirable, as in general the earlier lesions tend to have a better prognosis than those with more advanced stages of disease.

The goal of reducing the incidence and mortality from squamous carcinoma of the cervix can be achieved

through screening programs, as described in this and other reports. The key element in cervical control programs has been, and continues to be, cytologic screening. In areas where facilities and resources for diagnosis and treatment are limited, emphasis should be on increasing the screening net to encompass as many women at risk as possible, particularly those who have never been screened, rather than on increasing the frequency of smears within a given population.

The data presented in this report are a measure of the levels of activity that have occurred in British Columbia to achieve significant results. It should be noted that most of the initial decrease in incidence and mortality occurred before the introduction of the colposcopy component of our program. There is no doubt, however, that before colposcopy, in many women who were managed by the traditional method of cone biopsy for assessment followed by hysterectomy, the disease was overtreated. Colposcopy represents an advance that developed as a response to the problem of increasing disease rates noted in younger women in the early 1970s. From the data presented, it is apparent that only a small proportion of all women (approximately 10%) within a screened population such as ours will have an abnormality on the Papanicolaou test. Of these, approximately 75% of smears showing squamous atypia will be in the low-grade category of mild dyskaryosis or benign atypia. It is apparent that if resources are needed to evaluate and assess colposcopically all women seen initially with these mild degrees of change, then the cost will be considerable. Furthermore, if the practice is then to treat these early, low-grade lesions, the cost escalates dramatically. Many studies[22-25] have shown that, in particular, the milder grades of atypia may regress spontaneously without specific treatment.

Reports[26-28] have appeared advocating the use of human papillomavirus deoxyribonucleic acid testing with cervical cytology and colposcopy in an attempt to better identify and characterize precursor lesions. These tests, however, involve additional expense and do not represent a substitute for the traditional method of cytologic screening.

Efforts directed toward the development of effective automated screening systems continue and offer the promise of reducing the cost of cytologic screening and increasing the reliability of the test. However, until better methods are evident and affordable, every effort should be made to continue with existing technology and expanding the use of cytologic screening programs. Areas with established programs should continue to make the program as comprehensive as possible and work toward improving quality control in their cytology and colposcopy programs.

The use of colposcopy as an adjunct to cervical cancer

detection and treatment programs is particularly helpful but needs to be used appropriately and with expertise to optimize its potential.

The aim of further reducing death rates from cervical cancer is achievable with current knowledge and technology and represents a continuing challenge for all involved in these programs.

Factors affecting the dose response to oxytocin for labor stimulation

Andrew J. Satin, MD,[a] Kenneth J. Leveno, MD,[a] M. Lynne Sherman, RN,[a] and Donald D. McIntire, PhD[b]

Dallas, Texas

For nearly 40 years synthetic oxytocin has been used for labor stimulation by titrating dosage rate to uterine contractions. We used a computerized data base to determine variables affecting the dose response to oxytocin in 1773 pregnancies. Statistically important predictors of required oxytocin dosage included cervical dilatation, parity, and gestational age. Maternal body surface area was found to be associated with a higher oxytocin dosage in women undergoing induction of labor. However, the broad range of the statistical confidence intervals precluded prediction of a given pregnancy's oxytocin requirement. (Am J Obstet Gynecol 1992;166:1260-1.)

Key words: Oxytocin, labor augmentation, labor induction

Labor stimulation with oxytocin is a very common practice in modern obstetrics. The contemporaneous method of administering oxytocin is essentially an individualized bioassay wherein dosage is titrated to uterine contractions. Typically, oxytocin is infused beginning with a low dose and thereafter slowly increasing the infusion rate until adequate contractions are achieved.[1] This method is applied regardless of pregnancy factors that could conceivably influence dose-response characteristics for oxytocin. For example, it seems that an obese woman should require a higher oxytocin dosage than a petite woman with similar pregnancy characteristics. Although many clinicians suspect that several pregnancy factors may influence the response to oxytocin, these potential oxytocin dose-response factors have not been investigated.

The purpose of this study was to determine if factors such as maternal size, duration of pregnancy, and cervical dilatation influenced the oxytocin dosage required for labor stimulation. If such factors were identifiable, the resultant ability to adjust oxytocin dosage regimens a priori could potentially improve labor stimulation efficiency.

Material and methods

This study involving 1773 pregnancies was performed at Parkland Memorial Hospital. Between Nov. 1, 1990, and May 31, 1991, oxytocin was administered by nurses trained in labor stimulation according to a written protocol. The oxytocin regimen described was part of another ongoing investigation. Briefly, the oxytocin regimen used consisted of a starting dose of 6 mU/min with incremental increases of 6 mU/min at 20-minute intervals with a maximum permitted infusion rate of 42 mU/min. Half-dose increments were used in the presence of uterine hyperstimulation. The infusate consisted of 20 U of synthetic oxytocin (United States Pharmacopeia) diluted in 1000 ml lactated Ringer's solution. Electronic fetal monitoring was required, and physicians were in attendance in the labor unit. Oxytocin dosages were regulated to achieve a minimum of three contractions per 10 minutes while avoiding uterine hyperstimulation, which was defined as uterine contractions of ≥2 minutes duration or six or more contractions per 10 minutes. Induction of labor was carried out in pregnancies requiring intervention for maternal or fetal complications without spontaneous labor or ruptured membranes. Cases classified as having augmentation of labor included those pregnancies with ineffective spontaneous labor or rupture of membranes without labor.

Nurses attended each delivery and completed a perinatal data sheet. Research nurses assessed the data for consistency and completeness before electronic storage. Moreover, the labor stimulation record, which contained oxytocin infusion rate, cervical examination, fetal heart rate, contraction quality, and labor complications, was abstracted by the investigators and computerized.

Stepwise multiple regression analysis was performed for pregnancy factors that may be associated with the maximum oxytocin dosage required for labor stimulation. These factors included maternal age, race, parity, cervical dilatation, and body surface area; delivery route; use of epidural analgesia; presence of chorioam-

nionitis; gestational age; birth weight; and condition of newborn.

The significance level for entry of variables into the model and for remaining in the model was $p < 0.15$. Multiple regression analysis was performed on the model selected by the stepwise analysis to account for intercorrelations between variables. The selected prediction equation estimated by multiple linear regression was then used to establish 95% confidence intervals for the prediction of the maximum oxytocin dosage. The statistical analysis was performed with the SAS/STAT statistical program.[2]

Results

Of the 1773 pregnancies, 1011 (57%) received oxytocin for labor augmentation and the remaining 762 for labor induction. Results of multiple regression analysis for maternal, neonatal, and labor demographics in relationship to required maximum oxytocin dosage are summarized in Table I. The statistically important predictors of the maximum dosage of oxytocin required during both labor augmentation and induction included cervical dilatation, parity, and gestational age. Specifically, higher oxytocin dosages were required when cervical dilatation was ≤2 cm, the mother was nulliparous, and duration of pregnancy was ≤36 weeks. Maternal body surface area was found to be associated only with higher oxytocin dosage in women undergoing labor induction. These significant predictors of the infusion rate of oxytocin were then used to derive a predictive formula for the maximum rate of oxytocin infusion. For example, the formula predicted that a term, nulliparous woman with a cervix dilated 2 cm would require a maximum dosage of 36 mU/min for labor induction. However, the standard deviation of this prediction exceeds 20 mU/min, and the 95% confidence interval of the predicted infusion rate would range from 2 to 42 mU/min.

Comment

Our data confirm the suspicion of clinicians that cervical dilatation, gestational age, and parity influence pregnancy response to oxytocin. However, the broad range of the confidence intervals precludes prediction of a given pregnancy's oxytocin requirement. In conclusion, knowledge of cervical dilatation, gestational age, parity, or body surface area offers no practical predictive advantage in determining the dose response to oxytocin used for labor stimulation. Until the pharmacokinetics of oxytocin are better understood, each pregnant woman receiving oxytocin for labor stimulation will continue to represent an individual bioassay.

Middle cerebral artery flow velocity waveforms in normal and small-for-gestational-age fetuses

Giancarlo Mari, MD, and Russell L. Deter, MD
New Haven, Connecticut, and Houston, Texas

The middle cerebral artery flow velocity waveforms were obtained in 16 normal fetuses in a longitudinal study and in 128 normal fetuses in a cross-sectional study with pulsed Doppler ultrasonography. The pulsatility index values of the middle cerebral artery were higher at 25 to 30 weeks' gestation than those observed during the two periods of major cerebral cellular multiplication in the human fetus. In 9 of the 16 fetuses studied longitudinally we compared the pulsatility index values obtained at the end of gestation with those obtained at 1 month after delivery; no significant difference was observed. The pulsatility index of the middle cerebral artery was also determined in 33 small-for-gestational-age fetuses. A middle cerebral artery pulsatility index value below our normal range was recorded in 9 of the 33 small-for-gestational-age fetuses (27.3%). These small-for-gestational-age fetuses with abnormal pulsatility index values had a significantly higher incidence of abnormal fetal heart rate and admission into the neonatal intensive care unit. There were three deaths in the nine small-for-gestational-age fetuses with abnormal pulsatility index values (33.3%) and three deaths in the 24 small-for-gestational-age fetuses with normal pulsatility index values (12.5%). Our data indicate that the pulsatility index of the middle cerebral artery in the normal human fetus has a parabolic pattern during pregnancy and does not change significantly after delivery. The results suggest that the small-for-gestational-age fetus with a normal middle cerebral artery pulsatility index is at lower risk than the fetus with abnormal pulsatility index values; moreover, management of the small-for-gestational-age fetus may be aided by the study of the middle cerebral artery waveforms. (Am J Obstet Gynecol 1992;166:1262-70.)

Key words: Middle cerebral artery, small for gestational age, intrauterine growth retardation, pulsatility index, brain-sparing effect

Several studies of fetal cerebral artery blood flow velocity waveforms have been reported in the third trimester of pregnancy in normal, intrauterine growth retarded (IUGR),[1, 2] and anemic fetuses.[3] The studies emphasized a decrease in downstream impedance in the cerebral vasculature of IUGR fetuses attributed to a brain-sparing effect.[1] Additionally, a reduction in PO_2 established in the umbilical artery through cordocentesis at the end of gestation[4] has been associated with the decrease in pulsatility index noted in the cerebral arteries of normal fetuses during this period of gestation.[5] Normal values for the velocity waveforms of different cerebral arteries have been published by a number of investigators.[1, 2, 5] In many cases the pulsatility index values were derived from cross-sectional Doppler studies, and no longitudinal report on the cerebral blood flow velocity waveforms early in the second trimester of pregnancy (i.e., 15 weeks) has been presented.

Our study presents a serial assessment of the pulsatility index for the middle cerebral artery starting early in the second trimester. Additionally, the pulsatility index of the middle cerebral artery was assessed in 128 normal fetuses in a cross-sectional study. The data obtained in the cross-sectional study have permitted an evaluation of the variability of the pulsatility index within a given population and have provided the basis for the development of normal values of the pulsatility index for the middle cerebral artery in the human fetus. The predicted values derived from the cross-sectional study were compared with the average longitudinal curve. Furthermore, to evaluate the variability of the middle cerebral artery velocity waveforms before delivery and in the first month after delivery, the pulsatility index value of the middle cerebral artery was obtained in nine normal fetuses at the end of gestation and at 1 month post partum. Finally, middle cerebral artery velocity waveforms of 33 small-for-gestational-age (SGA) fetuses are reported and compared with those obtained in normal fetuses.

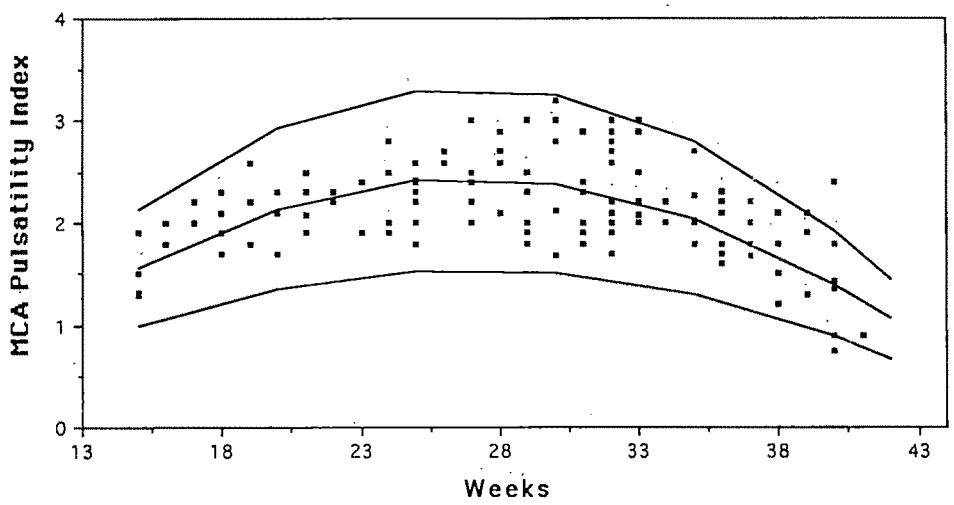

Fig. 1. Normal range of middle cerebral artery pulsatility index (*PI*) as a function of gestational age constructed from study of 128 normal fetuses. Lower limit = Predicted pulsatility index − (2 × 0.184 × Predicted pulsatility index); Upper limit = Predicted pulsatility index + (2 × 0.184 × Predicted pulsatility index).

Material and methods

This study was done with data from 16 normal fetuses (group 1), 128 normal fetuses in a cross-sectional study (group 2), and 33 SGA fetuses (group 3). Informed consent was obtained from all patients. Twenty-five subjects in our study population participated in other investigations.[6] The women in the first two groups were delivered of their fetuses after 37 weeks of gestation; comprehensive pediatric assessment revealed no evidence of growth abnormalities or congenital anomalies. Birth characteristics such as weight, length, head circumference, and abdominal circumference were within the normal ranges for singletons determined by Usher and McLean.[7] Nine normal fetuses monitored longitudinally were studied 1 month after delivery; two of them were studied four times in the first 6 months after delivery.

Fetal age determination. Fetal age in group 1 was determined from the date of the last menstrual period and confirmed by first-trimester and early second-trimester ultrasonographic examinations (crown-rump length, biparietal diameter, and femur diaphysis length measurement).[8]

Gestational age in groups 2 and 3 was determined by both menstrual history and sonographic assessment of fetal biometry from either a scan before 20 weeks' gestation or, if such a scan had not been performed, the first ultrasonographic assessment in this study. Gestational age was based on (1) the date of the last menstrual period when it differed by <2 weeks from the gestational age determined by sonographic parameters or (2) the sonographic assessment if the patient was unsure of the date of her last menstrual period or if the discrepancy between menstrual and sonographic gestational age was >2 weeks. SGA fetuses were defined on the basis of ultrasonographic measurements of head and abdominal circumferences[8] 2 or more SD below the mean and confirmed by a low birth weight.[7]

The data obtained from the Doppler ultrasonographic studies were not used in the clinical management of the patients.

Doppler ultrasonographic examinations. The normal and SGA fetuses were examined when the mothers were in a semirecumbent position. Exposure of the fetal brain to Doppler ultrasonography was kept to a minimum estimated to be around 1 to 5 minutes. Examination of the middle cerebral artery was performed as reported previously.[9] A PASS II (General Electric Medical Systems, Milwaukee, Wis.) with pulsed Doppler beam was used in conjunction with a 2.5 MHz real-time imaging device with a 2 mm sample volume. A 0 to 50 Hz pass filter was used. Ultrasonographic energy was 114 mW/cm² spatial peak temporal average intensity; although it exceeded the 100 mW/cm² level recommended by the Food and Drug Administration for fetal Doppler ultrasonography,[10] the intensity was well below the known peak acoustic field emission of 180 mW/cm² for preenactment ultrasonographic diagnostic devices. In addition, the American Institute of Ultrasound in Medicine recently reported that no independently confirmed significant biologic effects in mammalian tissues have been noted with focused ultrasonographic intensities below 1 W/cm².[11]

Doppler examinations of the middle cerebral artery in the fetuses of group 1 were carried out at 3- to 4-week intervals from 15 to 18 weeks' gestational age

y, Pulsatility index; *x*, gestational age.

(mean ± SD: 16.3 ± 1.5 weeks) to 35 weeks, and at 1- to 3-week intervals thereafter until delivery. After 35 weeks we decided to study the middle cerebral artery more frequently because the time of delivery could not be predicted. The middle cerebral artery of nine fetuses in the longitudinal study was studied as seen in utero at 1 month after delivery. In two fetuses the middle cerebral artery was studied at 1, 4, 12, and 24 weeks after delivery.

The gestational age of the fetuses in group 2 at the time of the study ranged between 15 and 41 weeks (29 ± 7.2 weeks, mean ± SD). In 30 fetuses, two-dimensional directed pulsed Doppler waveforms (Acuson 128; Acuson Co., Mountain View, Calif.) were compared with color-flow Doppler imaging (Acuson 128). Before the middle cerebral artery was interrogated with pulsed Doppler ultrasonography, the color-flow mapping was successively used to confirm that the sample volume had been positioned on the middle cerebral artery and that the angle between the beam and the vessel was <20 degrees.

The gestational age of the SGA fetuses (group 2) ranged from 20 to 37 weeks (31 ± 4.3 weeks, mean ± SD) at the time of the study and from 24 to 42 weeks (33.6 ± 3.9 weeks, mean ± SD) at the time of delivery.

Data analysis. The Doppler velocity waveforms were recorded on videotape, and a digitized computer system (Digisonics Inc., Houston) calculated the following variables: peak systolic velocity, lowest diastolic velocity, and mean velocity. Three consecutive waveforms were analyzed, and the results were averaged. The pulsatility index (Peak systolic velocity − Lowest diastolic velocity)/Mean velocity)[12] was then calculated. Measurements were obtained only during fetal apnea, which was defined as the absence of visible changes in the waveform patterns for ≥15 waveforms.

The intraobserver error (coefficient of variation) for the pulsatility index of the middle cerebral artery was 5.6% as reported previously.[13]

Changes in pulsatility index with gestational age for the fetuses of group 1 were characterized quantitatively by fitting mathematic functions to the experimental data. Regression analysis was used to compare the pulsatility index with gestational age for each fetus. We looked for the optimal polynomial model on the basis of two criteria: (1) coefficients different from zero and (2) maximal coefficient of determination (R^2). Analysis of variance was used to determine whether the regression accounted for a significant part of the variability in the dependent variable. A p value <0.05 was considered to indicate statistical significance. Assessment of the variability of the pulsatility index of the middle cerebral artery during pregnancy was carried out with the measurements made on the fetuses in group 2. There was only one pulsatility index measurement per fetus in this data set. A second-degree polynomial was fitted to the data with the method of least squares and predicted values calculated at each time point where an actual measurement was made. The differences between actual and predicted pulsatility index values were determined and plotted. Because there appeared to be an increase in variability with menstrual age, these differences were expressed as a percentage of the predicted values (percent difference). The mean and SD of the percent difference were calculated, and twice the latter was used as the measure of pulsatility index variability at different times in pregnancy (Fig. 1).

A paired Student's t test was used for statistical com-

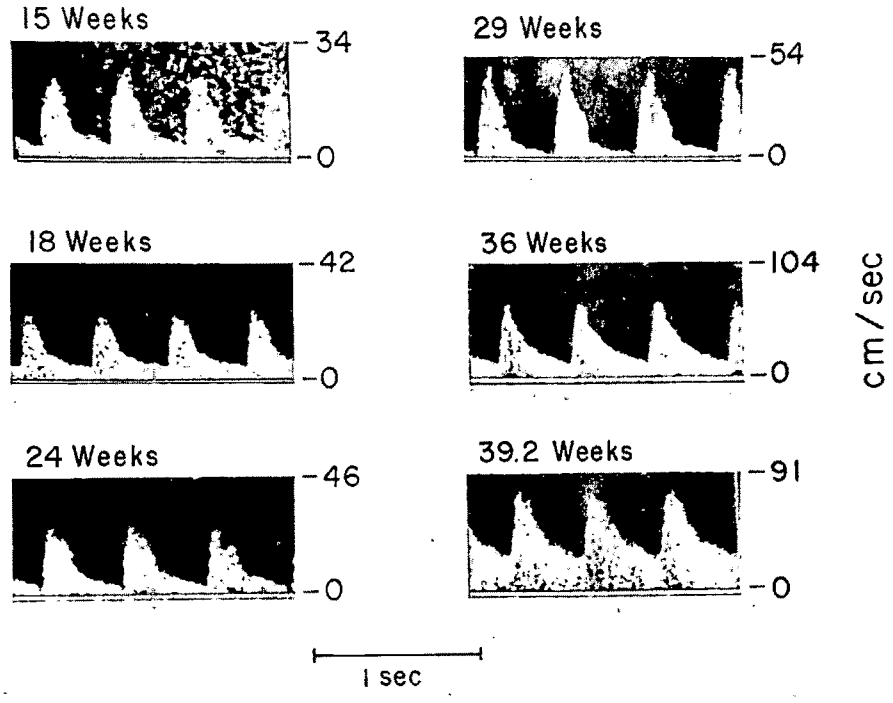

Fig. 2. Flow velocity waveforms of fetal middle cerebral artery velocity waveforms at different gestational ages.

parison of pulsatility index values in the middle cerebral artery of the fetuses and infants. A probability value of <0.05 was considered to indicate statistical significance.

The pulsatility index values for the SGA fetuses (group 3) were measured and plotted with our normal range.

In the SGA fetuses we obtained the sensitivity, specificity, positive predictive value, and negative predictive value for the middle cerebral artery pulsatility index, with the test status being above or below our normal reference range for gestational age (predicted value ± 2 SD) and the outcome status being presence or absence of adverse perinatal outcome (defined as admission to the neonatal intensive care unit for >12 hours or perinatal death).

Results

Initially the patients of group 1 were 34 normal fetuses. The data of 18 fetuses monitored longitudinally were not included in our analysis because of preterm labor ($n = 1$); first measurement after 18 weeks' gestation, an inadequate number of measurements, or both ($n = 13$); hypertension ($n = 3$); or multicystic kidney ($n = 1$). The mothers of group 1 were delivered of fetuses between 38 and 42 weeks (39.6 ± 1.1 weeks, mean ± SD). A total of 144 examinations were performed. On 16 occasions the middle cerebral artery could not be evaluated on first attempt, because of either fetal position or fetal movement. In these cases the examination was repeated within 1 week. On six occasions the measurement of the middle cerebral artery was not obtained.

In each of the 30 fetuses studied with pulsed Doppler and color flow mapping the sample volume was found over the middle cerebral artery in the color image after the middle cerebral artery was obtained with pulsed Doppler ultrasonography. The angle was always <20 degrees.

The best model in group 1 was a second-order polynomial ($y = a_0 + a_1x + a_2x^2$) (Table I). Coefficient a_0 was different from zero in nine cases; coefficient a_1 was different from zero in 13 cases; and coefficient a_2 was different from zero in 14 cases. The middle cerebral artery waveforms manifested a higher diastole at 15 to 20 weeks and at the end of gestation (Fig. 2); this was associated with a lower pulsatility index value between 15 and 20 weeks' gestation and, late in the third trimester of pregnancy, a higher value at 25 to 30 weeks' gestation. Fifteen of the 16 individual fetuses showing evidence of a parabolic change in pulsatility index with gestational age were used to specify the average longitudinal curve by determination of the mean coefficient values. The function is given in Table II.

PI, Pulsatility index; *GA*, gestational age.
*PI = $-2.256 + (0.3293GA) + (-0.00611GA^2)$.
†PI = $-1.9763 + (0.32737GA) + (-0.006071GA^2)$.

In nine infants the pulsatility index of the middle cerebral artery after delivery did not show any significant difference when compared with that obtained at the end of gestation (1.32 ± 0.24 vs 1.29 ± 0.19, mean ± SD) (Fig. 3). In two normal fetuses studied four times after delivery the pulsatility index did not appear to change when compared with the values obtained at the end of gestation (Fig. 4).

The polynomial function Pulsatility index = $-1.9763 + 0.32737$ (menstrual age) $- 0.0060717$ (menstrual age)^2 $R^2 = 44.8\%$ fitted to the cross-sectional data is given in Fig. 1. All coefficients were statistically significantly different from zero by t test. Reasonable agreement was obtained between this standard curve for the pulsatility index of the middle cerebral artery and values derived from the average longitudinal curve for this parameter as shown in Table II. Use of the percent deviations eliminated the change in variability with menstrual age, the mean percent difference being -0.08% (not significantly different from zero by t test) and the SD 18.4%. The standard curve for the pulsatility index of middle cerebral artery constructed from these data is given in Table III.

One SGA fetus studied at 20 weeks' gestation presented head and abdominal circumference below our reference range; the pregnancy was complicated by oligohydramnios. This fetus had reverse flow in the umbilical artery, and fetal demise was diagnosed 4 weeks later.

All fetuses estimated to be SGA in utero turned out to be SGA at birth. In 9 SGA fetuses the middle cerebral artery was below our normal reference range (Fig. 5): 2 of these died in utero; 1 died soon after birth; 5 had fetal distress or were admitted to the neonatal intensive care unit; and 1 was normal. Two of the fetuses transferred to the neonatal intensive care unit for further evaluation had a good short-term outcome and were transferred to the normal nursery within 12 hours. In two fetuses who died in utero the time between the study of the middle cerebral artery and fetal demise ranged from 2 to 4 weeks. The SGA fetuses with a normal value of pulsatility index ($n = 24$) had no complications ($n = 17$); 1 fetus died in utero, 2 fetuses died after delivery, and 4 others had fetal distress or were transferred to the neonatal intensive care unit. The two fetuses with normal middle cerebral artery pulsatility indexes who died shortly after birth were studied 2 days and 7 weeks before delivery, respectively.

Table IV provides calculations of sensitivity, specificity, and positive and negative predictive values for the

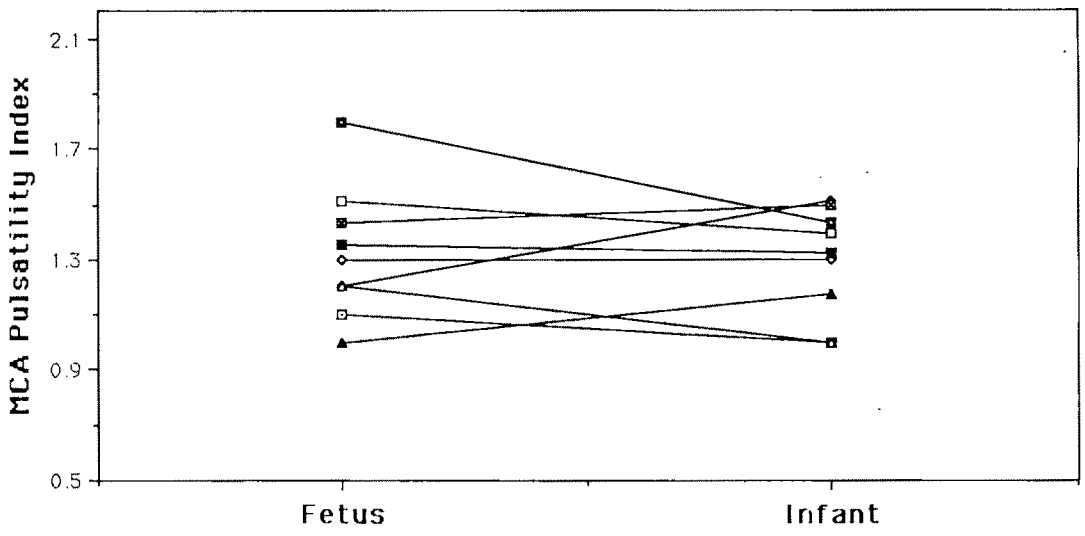

Fig. 3. Middle cerebral artery *(MCA)* pulsatility index values before delivery and at 1 month after delivery in nine normal infants ($p > 0.05$).

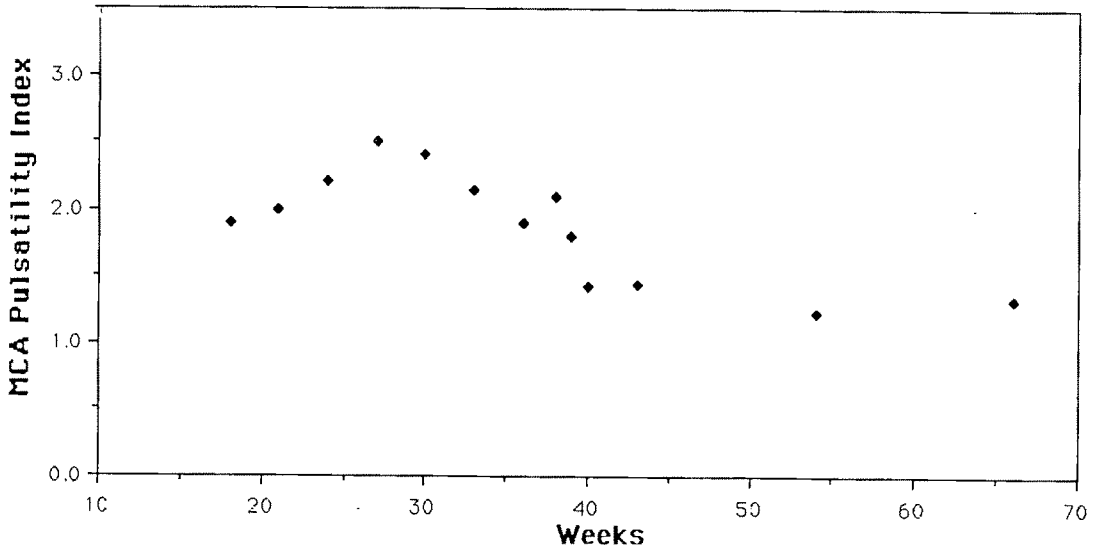

Fig. 4. Middle cerebral artery *(MCA)* pulsatility index values in one infant studied from 16 weeks' gestation to 24 weeks after delivery.

middle cerebral artery pulsatility index below the normal range and adverse perinatal outcome.

Table V provides data on the six perinatal deaths.

The rate of cesarean sections was 42% in the SGA fetuses with normal middle cerebral artery pulsatility index and 55% in the SGA fetuses with abnormal middle cerebral artery pulsatility index. Six of the pregnant women of group 2 had hypertension during their pregnancy.

Comment

Wladimiroff et al.[1] reported that the pulsatility index of the fetal internal carotid artery did not change significantly between 26 weeks' gestation and the term of pregnancy. They suggested that IUGR fetuses could undergo a brain-sparing effect, similar to that reported in the animal literature. Successively, Van Den Wijngaard et al.[5] showed that the pulsatility index of the fetal internal carotid artery decreases during gestation. These authors attributed this change to the relatively low oxygen observed by Soothill et al.[4] in the umbilical artery at the end of pregnancy.

Vyas et al.[14] studied the middle cerebral artery in normal and hypoxemic fetuses and reported that the end-diastolic velocities were absent in 11 of 42 normal fetuses at 18 to 25 weeks' gestation and in 12 of 50

†Predicted value + (2 × 0.184 × Predicted value).

fetuses at 26 to 33 weeks. They reported that maximum reduction in pulsatility index is reached when the fetal Po_2 is 2 to 4 SD below normal for gestation. When the oxygen deficit is greater there is a tendency for the pulsatility index to rise; this presumably reflects the development of brain edema.

Veille and Cohen[15] performed Doppler studies of the middle cerebral artery on 17 fetuses who were SGA at the time of delivery. Results were compared with a group of 25 fetuses who had a normal weight for gestational age at the time of delivery. No difference was found in either the systolic/diastolic ratio[16] or the Pourcelot index[17] of the middle cerebral artery.

It is possible that the physiologic fetal hypoxemia reported by Soothill et al.[4] at the end of gestation could contribute to the low pulsatility index observed in this period of gestation. However, we have observed that the low pulsatility index found in nine normal fetuses late during pregnancy does not change significantly after delivery. Additionally, our study indicates that the pulsatility index of the middle cerebral artery is lowest between 15 and 20 weeks' gestation and at the end of gestation. To postulate another explanation for the low pulsatility index observed in the normal fetus at the end of gestation, the factors that could influence the pulsatility index in the cerebral circulation must be examined. The pulsatility index of the middle cerebral artery is decreased in conditions that suggest a decreased cerebral impedance to blood flow caused by either mechanical factors[18] or fetal hypoxemia such as that observed in IUGR fetuses[1] and in the anemic fetus after intravascular transfusion.[3] Therefore our results could indicate a decreased cerebral vascular impedance to blood flow during these two periods of gestation.

That reasonable agreement was obtained between the results of the longitudinal and cross-sectional studies in normal fetuses supports the concept that this pattern of change in the pulsatility index of the middle cerebral artery is physiologic. An explanation for lower vascular impedance during early and late pregnancy

Table IV. Predictive validity of middle cerebral artery pulsatility index below the normal range for gestational age for adverse perinatal outcome

	Disease state

may be found in studies of the development of the human brain. Dobbing and Sands[19] studied human fetal brains; they estimated total cell numbers by chemical analysis of deoxyribonucleic acid–phosphorus in the forebrain, cerebellum, and brain stem. These authors calculated the whole brain values as the sum. They assumed that total tissue deoxyribonucleic acid represented total number of cells. They demonstrated that in the human species there are two periods of major cellular multiplication: one at 15 to 20 weeks' gestation and one that commences in the third trimester and probably ends in the second year of postnatal life. We have observed a lower pulsatility index in the middle cerebral artery during these two periods of increased deoxyribonucleic acid synthesis. It can be speculated that during these two periods of major cellular multiplication there is an increased metabolic requirement in the human fetal brain and a lower cerebral vascular impedance to blood flow.

Our results are in conflict with those reported by Vyas et al.[14] because we have observed the end-diastolic velocity in the middle cerebral artery velocity waveforms in almost all of the fetuses. This discrepancy may be caused by the use of different high-pass filters: 125 Hz in their study, 0 to 50 Hz in the current study. We think it is important to use a low-frequency high-pass filter when studying the middle cerebral artery because of the possibility of missing the diastolic component of the waveforms, which will affect the pulsatility index.

To date, studies of the fetal cerebral circulation have been directed mainly at recognizing IUGR fetuses. An IUGR fetus can be either a fetus with low growth rate caused by chronic hypoxia at risk for adverse perinatal outcome or a small, normally growing baby. Animal and human experiments have shown that the brain-sparing effect is present in conditions of fetal hypoxemia.[14, 20] It is reasonable to assume that the brain-sparing effect is present in the fetus with low growth rate and not in the normal small baby. The results of the SGA fetuses reported in this study indicate that in some SGA fetuses there is a pulsatility index value below the normal range, which suggests a brain-sparing effect. The difference between the fetuses with normal versus abnormal middle cerebral arterial pulsatility index may be clinically important. The fetuses with abnormal pulsatility index had a greater incidence of adverse perinatal outcome.

Recently we proposed that the brain-sparing effect is transitory,[21] as reported during prolonged hypoxemia in animal experiments,[22] and the overstressed human fetus loses the brain-sparing effect. This hypothesis is further supported by the recent findings of Vyas et al.[14] In our series three SGA fetuses with normal middle cerebral artery pulsatility indexes died, the first in utero and the other two shortly after birth. It is possible that these fetuses had a brain-sparing effect during the pregnancy that was not present when we studied the fetuses.

As our study indicates, the brain-sparing effect can be present early in pregnancy (i.e., 20 weeks). This can be clinically important because of the possibility of early recognition of the fetus at higher risk for adverse perinatal outcome.

In conclusion, our study shows that (1) the pulsatility index of the middle cerebral artery of the normal human fetus has a parabolic pattern during pregnancy; (2) a physiologic lower pulsatility index value in the middle cerebral artery of the normal human fetus at 15 to 20 weeks' gestation and late in the third trimester is associated with an increased deoxyribonucleic acid synthesis in the fetal brain; (3) the pulsatility index of the middle cerebral artery after birth in nine normal fetuses did not change significantly from the pulsatility index obtained at the end of gestation; (4) a brain-sparing effect can be present early during gestation (i.e., 20 weeks); and (5) an abnormal pulsatility index of the middle cerebral artery in the SGA fetus is associated with worse fetal outcome.

I thank Dr. James F. Jekel, Dr. Brian Kirshon, Matthew Massicotte (Yale Medical School Student) and Laura J. Bryson (Baylor Medical School Student) for their help with this article.

Inferior vena cava flow velocity waveforms in appropriate- and small-for-gestational-age fetuses

Giuseppe Rizzo, MD,[a] Domenico Arduini, MD,[a] and Carlo Romanini, MD[b]
Rome and Ancona, Italy

Reference ranges of inferior vena cava flow velocities were constructed from a cross-sectional study of 118 appropriate-for-gestational-age fetuses of 18 to 40 weeks of gestation. Blood flow velocity waveforms were recorded with color and pulsed Doppler equipment. Peak velocities and time velocity integrals were measured from inferior vena cava during systole, early diastole, and atrial contraction. The systolic-to-diastolic ratios between the peak velocities and time velocity integrals were calculated, and the reverse flow with atrial contraction was quantified as the percentage of forward flow (percentage of reverse flow). Recordings were also obtained from 79 small-for-gestational-age fetuses free of structural and chromosomal abnormalities, divided into three groups according to umbilical artery velocity waveforms: normal pulsatility index values (group 1, $n = 26$), pulsatility index >95th percentile of our reference limits but presence of end-diastolic velocities (group 2, $n = 33$), and absence of end-diastolic velocities (group 3, $n = 20$). Fourteen fetuses of groups 2 and 3 were also studied at weekly intervals until the onset of antepartum late heart rate decelerations. In appropriate-for-gestational-age fetuses no changes were evident in peak velocities and time velocity integrals ratios, whereas the percentage of reverse flow significantly decreased with gestation. No significant differences were found between these values and those obtained in small-for-gestational-age fetuses of group 1. A significant increase of peak velocities and time velocity integrals ratios and of percentage of reverse flow was evidenced in fetuses of both group 2 and 3. The fetuses of groups 2 and 3 with a percentage of reverse flow above the 95% confidence interval showed a poorer perinatal outcome when compared with the fetuses of the same groups but with values inside the normal range. In the 14 fetuses longitudinally followed up until the onset of late heart rate decelerations a significant and progressive increase of peak velocities and time velocity integrals ratios and percentage of reverse flow was evidenced in spite of minimal changes in the pulsatility index from both umbilical artery and different peripheral fetal vessels. This study presents evidence that in small-for-gestational-age fetuses with abnormal Doppler-measured placental resistance the modified flow velocity patterns in the inferior vena cava seem to deteriorate progressively with advancing gestation. (Am J Obstet Gynecol 1992;166:1271-80.)

Key words: Venous blood flow, Doppler ultrasonography, fetal growth retardation

Abnormal inferior vena cava flow velocity waveforms have been described in different fetal pathologic conditions, including anemia,[1] nonimmune hydrops,[2] and arrythmias.[3, 4] Furthermore, abnormalities of inferior vena cava waveforms, were also found in growth-retarded fetuses, characterized by extreme compromise as expressed by the absence of end diastolic flow in umbilical artery.[3]

There is no account, however, on the longitudinal changes occurring in inferior vena cava blood flow patterns with the progression of normal pregnancy and on their modifications in growth-retarded fetuses with different degrees of compromise.

This study uses Doppler ultrasonography to establish reference ranges of velocity waveforms in the inferior vena cava of healthy fetuses from 18 to 40 weeks of gestation. Furthermore, it investigates possible modifications in the flow velocity waveforms of small-for-gestational-age (SGA) fetuses and relates the Doppler findings to the severity of fetal compromise.

Material and methods

Subjects. Reference ranges of inferior vena cava velocity waveforms were constructed from the cross-sectional study of 118 appropriate-for-gestational-age (AGA) fetuses (i.e., birth weight ranging between the 10th and 90th percentile). These fetuses were recruited from the routine antenatal clinic of our institution. All pregnancies were singleton and dated by certain last menstrual period and early second-trimester ultraso-

Because pulsatility index values obtained from umbilical artery, renal artery, internal carotid artery, and middle cerebral artery change with gestation, data are expressed as number of standard deviations by which they differ from their normal mean for gestation (Δ-values). *NS*, Not significant.

*Statistical significance was evaluated by unpaired t test and Fisher's exact test.

nography. Ultrasonographic examination at the time of Doppler studies showed all the fetuses to be structurally normal and of appropriate size for gestational age. Infants were born in good condition; their characteristics are reported in Table I.

Inferior vena cava velocity waveforms were also studied in 79 SGA fetuses. Entry criteria required (1) singleton gestation accurately dated by early second-trimester fetal biparietal diameter mesurement and (2) abdominal circumference <5th percentile of our reference limits (fetuses with a gestational age <28 weeks) or ultrasonographically estimated fetal weight (fetuses with a gestational age ≥28 weeks) <5th percentile for our population. The diagnosis of SGA (i.e., birth weight <5th percentile and newborn free of structural abnormalities) was confirmed postnatally in all included subjects. SGA fetuses were divided into three groups according to the results obtained at the Doppler examination of the umbilical artery as follows: (1) group 1, normal pulsatility index in the umbilical artery with respect to our reference limits for gestation[5] (n = 26); (2) group 2, abnormal pulsatility index in the umbilical artery (i.e., >95th percentile) but velocity waveforms characterized by the presence of end-diastolic velocities (n = 33); (3) group 3, abnormal pulsatility index in the umbilical artery and absent end-diastolic velocities (n = 20) (none of these fetuses had reversed flow in the umbilical artery).

The characteristics of these three groups of fetuses are reported in Table I. Although umbilical artery pulsatility index values were provided to the clinicians managing the cases, decisions on delivery were not undertaken on the basis of Doppler data.

Some of the SGA fetuses with an abnormal pulsatility index in the umbilical artery were also studied longitudinally at weekly intervals until delivery. To obtain a homogeneous group, we retained the data of the 14 fetuses (10 of group 2 and four of group 3) in whom antepartum late heart rate decelerations developed and who had been studied on at least four occasions 1 week apart (longitudinal study). In these fetuses heart rate monitoring was performed daily for a minimum of 45 minutes from the time of diagnosis onward. At the onset of late decelerations during Braxton Hicks contractions, an elective cesarean section was performed.

All the patients gave their informed consent to participate in the study.

Doppler recordings. Commercially available Ansaldo Hitachi Esacord 81 color Doppler equipment (Ansaldo Hitachi, Genoa, Italy) with 3.5 or 5 MHz convex probes was used for all measurements. In addition to the color flow mapping function, the machine was equipped with pulsed Doppler that had a carrier frequency ranging from 2.5 to 5 MHz. After identification of the inferior vena cava in a longitudinal plane on a sagittal view of the fetal trunk, the color flow mapping

function was superimposed. On the basis of previously reported techniques in the first 70 cases (45 AGA and 25 SGA) the pulsed Doppler sample volume was placed both at the inlet of inferior vena cava in the right atrium[3] and in the portion of inferior vena cava between the entrance of the renal vein and the ductus venosus.[2,4] A good coefficient of correlation was found between the measurements performed at the two sampling sites ($r > 0.84$). The latter sampling site was selected for the further examinations because of the significantly lower angle (mean ± 1 SD 21 ± 7 vs 39 ± 6 degrees, $p \leq 0.001$) between the Doppler beam and the direction of blood flow, as estimated on the color image.

Flow velocity waveforms were recorded from each fetus during periods of fetal rest without breathing movements. All the recordings were performed by one of the authors (G.R.).

Permanent records of all the velocity waveforms were obtained from the videotape by means of a strip chart recorder. The printouts were labeled with random numbers. The observer involved in the later analysis was not informed of the sequence of the printouts. Three components were identified in velocity waveforms as described by Reed et al.[5]: (1) systole (S wave), (2) early diastole (D wave), and (3) reverse flow during atrial contraction (A wave) (Figs. 1 and 2). Estimates of the peak velocities and time velocity integrals of the three components were made on 10 uniform and consecutive heart cycles with the digitizing tablet of a computer (Cardio 800, Kontron, Oxford). The following indices were calculated from these measurements: (1) ratio between the peak velocity of S and D waves, (2) ratio between time velocity intervals of S and D waves, and (3) percentage of reverse flow quantified as the percent of time velocity intervals during A wave with respect to total forward time velocity intervals.

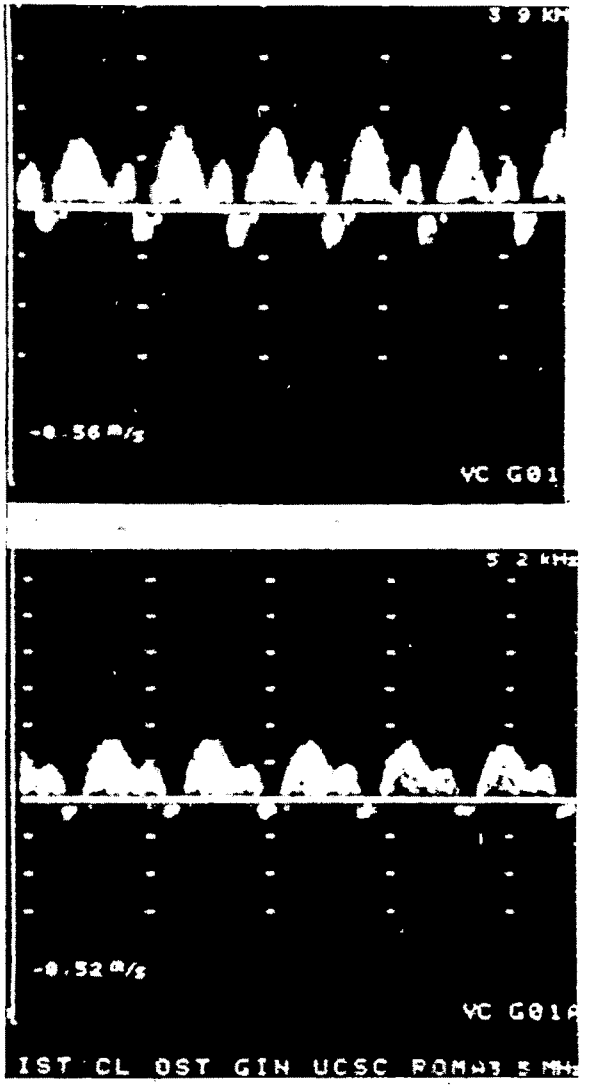

Fig. 1. Flow velocity waveforms from fetal inferior vena cava in AGA fetuses at 20 *(top)* and 39 *(bottom)* weeks of gestation with percentage of reverse flow *(bottom channel)* of 18.5 in former and 4.3 in latter.

Intraobserver variability was determined by examining 19 fetuses for two consecutive days. The maximum difference in the indices considered in the same fetus was 8.9% (mean 5.4%).

In all the fetuses studied blood flow velocity waveforms were also recorded at the level of the umbilical artery, middle cerebral artery, descending aorta, and renal artery with previously described techniques,[5] the pulsatility index was calculated as a measure of vascular impedance.[6]

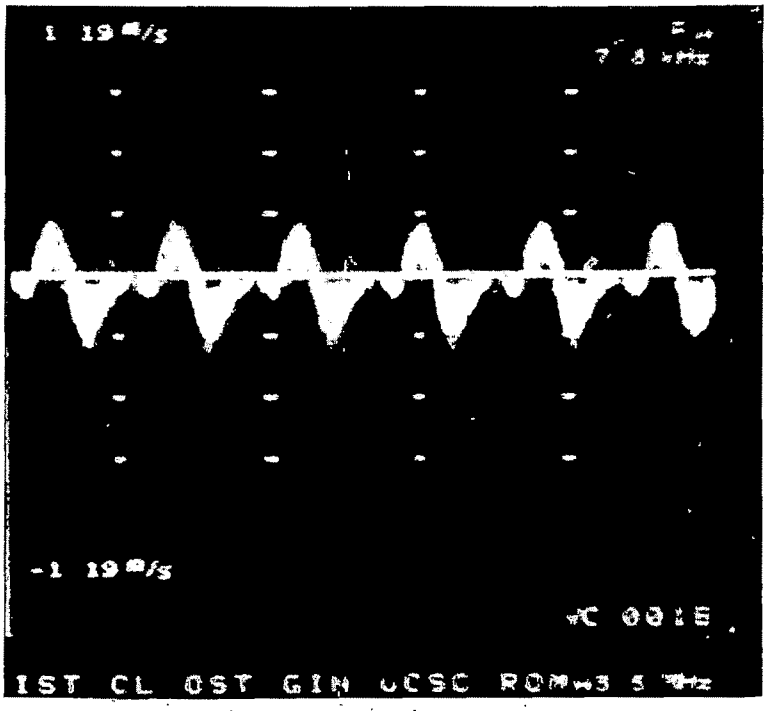

Fig. 2. Flow velocity waveforms from fetal inferior vena cava in SGA fetus of group 3 at 29 weeks of gestation with percentage of reverse flow *(top channel)* of 38.3.

Data analysis. Regression analysis was used to establish the mean and individual 95% confidence intervals of the relationship of the indices considered and gestation. Data are presented as mean ± 1 SD. For measurements changing with gestation data are also expressed as number of standard deviations by which they differ from their normal mean for gestation (Δ-values). Differences were evaluated by means of one sample and unpaired t test, Wilcoxon rank-sum test, and Fisher's exact test. The longitudinal changes in Doppler indexes were evaluated by the analysis of variance for repeated measurements. Regression analysis was used to test the relationships between the variables considered. Differences yielding $p \leq 0.05$ were considered significant.

Results

AGA fetuses. These fetuses showed a slight but not significant linear increase with gestation of the peak velocity S/D ratio (Fig. 3, $r = 0.191$, $p = 0.07$, mean value 1.757, SD 0.334). Similarly, no significant changes with gestation were found for the S/D time velocity intervals ratio (Fig. 3, $r = 0.091$, mean value 2.612, SD 0.997), whereas the percentage of reverse flow significantly and linearly decreased with gestation (Fig. 3, constant 24.671, slope −0.499, SD 2.557, $r = 0.775$, $p \leq 0.001$).

SGA fetuses, group 1. No significant differences were found in peak velocity S/D ratio (mean value = 1.63, SD 0.32, $t = 1.737$, not significant), S/D time velocity intervals ratio (mean value 2.62, SD 0.88, $t = 0.146$, not significant) and percentage of reverse flow (mean value 8.26, SD 2.41, Δ-value 0.09 SD, $t = 0.474$, not significant) when the values obtained in SGA fetuses with normal umbilical artery pulsatility index values were compared with those of AGA fetuses (Fig. 4).

SGA fetuses, group 2. A significant increase in peak velocity S/D ratio (mean value 1.945, SD 0.45, $t = 2.514$, $p \leq 0.01$), S/D time velocity intervals ratio (mean value 3.05, SD 1.51, $t = 1.934$, $p \leq 0.05$), and percentage of reverse flow (mean value 11.88, SD 6.04, Δ-value 1.36 SD; $t = 3.125$, $p \leq 0.005$) was found in this group of SGA fetuses when compared with AGA fetuses (Fig. 5). No relationships were evident between these indices and the pulsatility index values (absolute values and Δ-values) from umbilical artery, descending aorta, renal artery, and middle cerebral artery. Moreover, when the nine SGA fetuses with percentage of reverse flow values >95% confidence interval were compared with the remaining 24 SGA fetuses, a higher incidence of antepartum late heart rate decelerations (7/9 vs 6/24, Fisher's exact test $p \leq 0.01$), a shorter time interval between the recordings and delivery (median 11 days, range 3 to 21 vs 32, range 8 to 54, Wilcoxon test $p \leq 0.01$), and a lower umbilical artery pH (7.181 ± 0.022 vs 7.228 ± 0.021, $p \leq 0.001$) were evident. In addition, no differences were found between these two subgroups of fetuses either in birth weight (1442 ± 576 vs 1716 ± 354 gm, not significant) or in

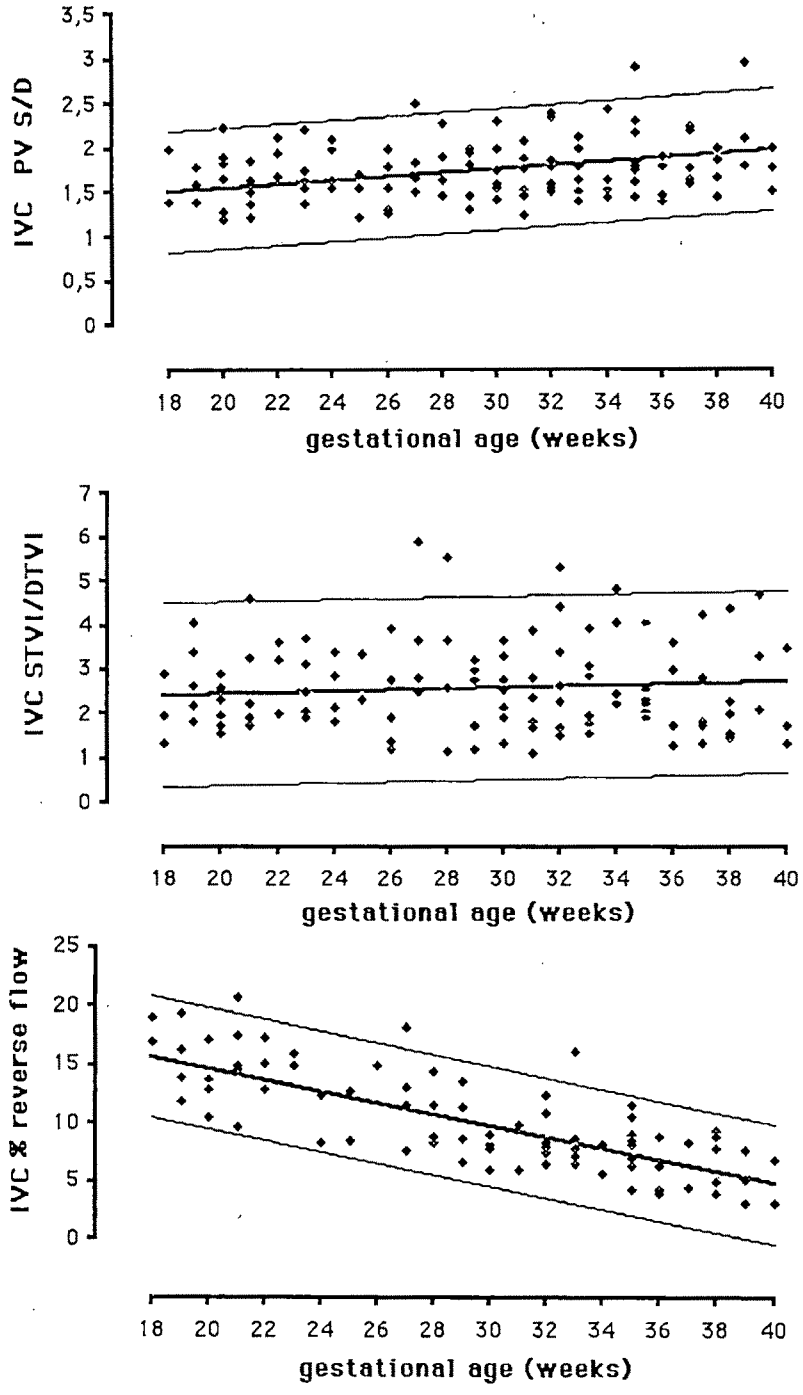

Fig. 3. Reference range (mean and linear regressions of individual 95% confidence intervals) with gestation of inferior vena cava *(IVC)* S/D ratios of peak velocities *(PV S/D)* and time velocity integrals *(STVI/DTVI)* and of percentage of reverse flow during atrial contraction.

pulsatility index values obtained from the different arterial districts considered. Moreover, the single case of neonatal death (intraventricular hemorrhage) that occurred in this group had a percentage of reverse flow value >95% confidence interval.

SGA fetuses, group 3. Highly significant differences were found in the comparison of SGA fetuses with AGA fetuses for peak velocities S/D ratio (mean value 2.39, SD 1.21, $t = 4.721$, $p \leq 0.001$), S/D time velocity intervals ratio (mean value 4.18, SD 2.84; $t = 5.294$, $p \leq 0.001$), and percentage of reverse flow (mean value 21.86, SD 10.53, Δ-value 5.06 SD, $t = 14.754$, $p \leq 0.001$) values (Fig. 5). Similarly, with group 2 fetuses no relationships were evident between inferior vena

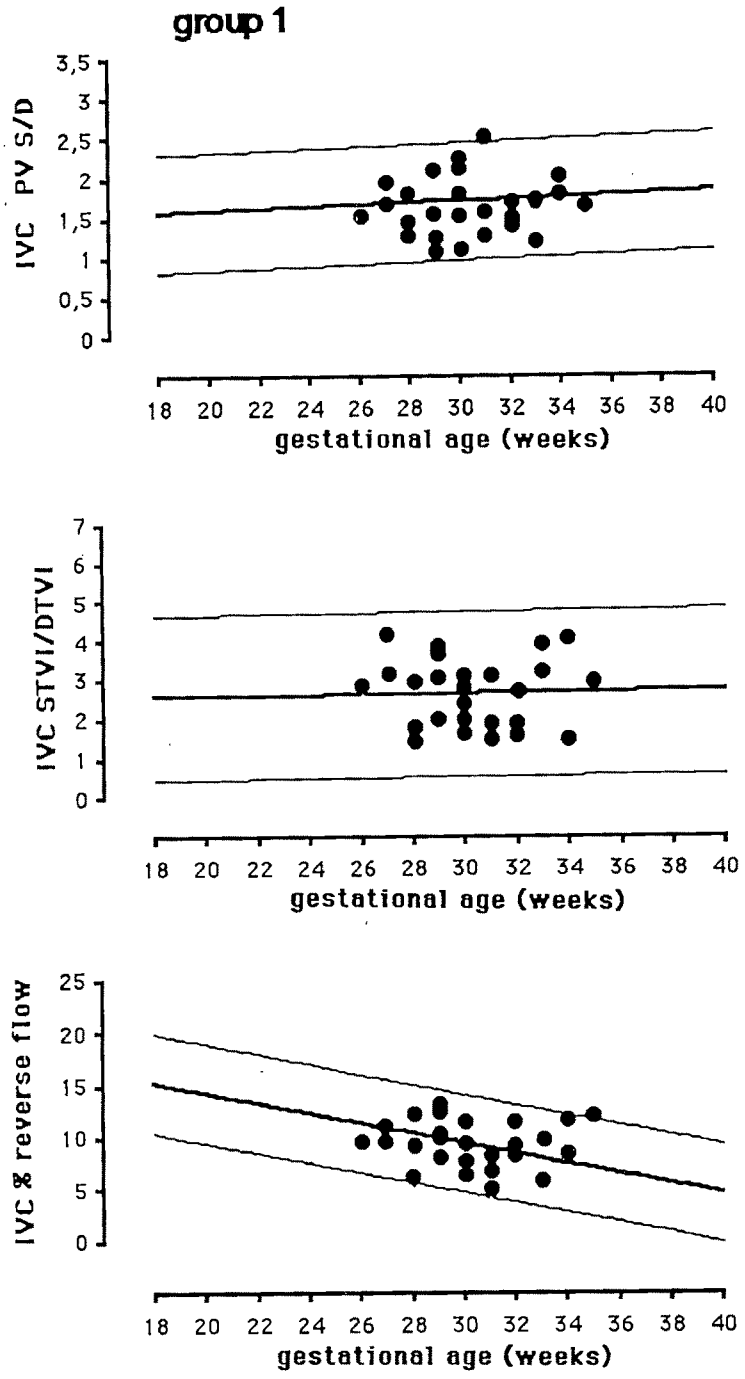

Fig. 4. Inferior vena cava *(IVC)* peak velocities *(PV)* S/D and S/D time velocity intervals ratios *(STVI/DTVI)* and percentage of reverse flow values of 33 SGA fetuses of group 1 (normal umbilical artery pulsatility index) plotted on reference range.

cava indices and pulsatility index values from arterial beds. In 14 fetuses of this group the percentage of reverse flow was >95th confidence interval, whereas the remaining six fetuses showed values inside the reference limits. When these two subgroups were compared, fetuses with abnormal percentage of reverse flow values showed a shorter interval between the recordings and delivery (median 5 days, range 0 to 11 vs 26, range 4 to 36, Wilcoxon test $p \leq 0.01$) and a higher incidence of antepartum late heart rate decelerations (12/14 and 2/6, Fisher's exact test $p \leq 0.03$). Three of the four neonatal deaths occurred in the fetuses with abnormal percentage of reverse flow. No further significant differences were noted between the two subgroups.

Longitudinal study. Each SGA fetus longitudinally

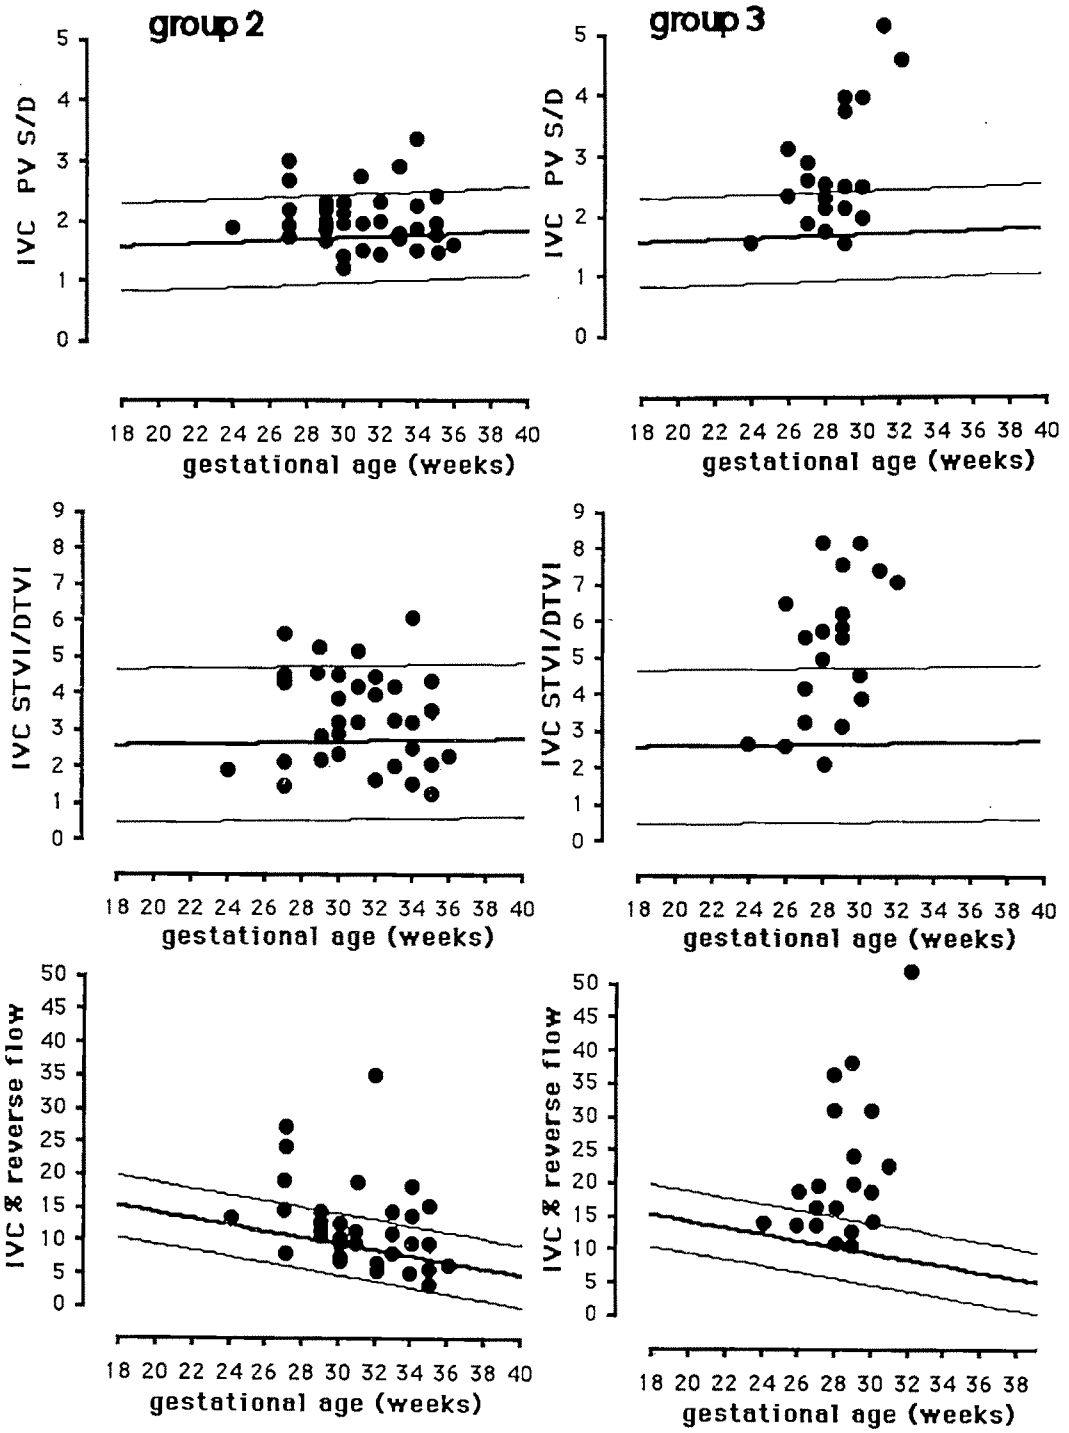

Fig. 5. Inferior vena cava *(IVC)* peak velocities *(PV)* S/D and S/D time velocity intervals ratios *(STVI/DTVI)* and percentage of reverse flow values of SGA fetuses of group 2 (increased umbilical artery pulsatility index and end-diastolic velocities present, *left side*) and group 3 (increased umbilical artery pulsatility index and absent end-diastolic velocities, *right side*) plotted on reference range.

studied underwent a mean of 4.71 Doppler recordings (range 4 to 7). Gestational age at the first study was 28.3 ± 2.5 and 32.1 ± 2.3 weeks at birth. Mean birth weight was 1379 ± 342 gm and mean umbilical artery pH was 7.218 ± 0.041. Although two of the fetuses of group 2 developed absent end-diastolic velocities in the umbilical artery, minimal overall changes were evidenced in pulsatility index from the umbilical artery ($F = 1.912$, $p \leq 0.05$) and middle cerebral artery ($F = 1.893$, $p < 0.01$). No significant changes were

Individual changes of peak velocities *(PV)* S/D and S/D time velocity intervals ratios *(STVI/DTVI)* and percentage of reverse flow values in 14 SGA fetuses studied longitudinally plotted on reference ranges. Values of each individual patient are connected by lines. *Open diamonds*, Absent end-diastolic velocities in umbilical artery, *IVC*, inferior vena cava.

found in descending aorta ($F = 0.348$, not significant;) and renal artery ($F = 0.879$, not significant) pulsatility index values. When analysis of variance was applied to inferior vena cava indexes a significant increase of peak velocity S/D ratio ($F = 6.123$, $p \leq 0.001$), the S time velocity intervals/D time velocity intervals ratio ($F = 7.423$, $P \leq 0.001$), and the percentage of reverse flow ($F = 14.23$, $p \leq 0.001$) was evident with advancing gestation (Fig. 6). No significant relationships were noted between these changes in inferior vena cava and the concomitant modifications of the pulsatility index from the umbilical artery and the middle cerebral artery.

Comment

Flow velocity patterns in the inferior vena cava are inversely related to the modifications of right atrial pressure.[7] In the human fetus the inferior vena cava blood

flow has a pulsatile pattern similar to that described in animal fetuses or in adults.[7, 8] In these models it has been demonstrated that the first forward wave begins to increase with atrial relaxation, reaches the peak during ventricular systole, and then falls to reach the nadir at the end of ventricular systole. The second forward wave occurs during early diastole, whereas a reverse flow is usually present in late diastole with atrial contraction. Simultaneous recordings of the inferior vena cava and descending aorta velocity waveforms have also allowed confirmation of the timing of these events in the human fetus.[3]

In normal pregnancy the peak velocities and the time velocity intervals values obtained during systole in the inferior vena cava exceeded the early diastolic values resulting in ratios >1. The absence of changes of the systolic-to-diastolic ratios with gestation suggests a constant filling pattern during systole and early diastole. Moreover, a significant decrease of reverse flow during atrial contraction was evident with advancing gestation. In the fetal lamb and in adults (animals and humans) the percentage of reverse flow is related to the pressure gradient present between the right atrium and the right ventricle at end diastole, which is related both to ventricular compliance and to ventricular end-diastolic pressure.[7, 9, 10] The noninvasive nature of the human fetal model does not allow differentiation between these factors, but it can be suggested that both may significantly contribute to the decrease of reverse flow evidenced throughout gestation. Previous studies have demonstrated that the fetal heart is less compliant than the neonatal heart[11] and that a progressive maturation of Doppler-measured indices of ventricular diastolic performance occurs, thus suggesting an improvement of ventricular compliance with advancing gestation.[12, 13] Furthermore, as a consequence of the reduction of placental resistances with gestation[5] it may be suggested that the right ventricle afterload falls. This might result in decreased residual volume and ventricular end-diastolic pressure.

SGA fetuses are a heterogeneous group that includes fetuses that are small because of racial or genetic factors and those that are growth retarded as result of malnutrition caused by uteroplacental insufficiency. The good outcome of the SGA fetuses belonging to group 1 and the normality of the pulsatility index in fetal arterial peripheral vessels make the former etiology for these fetuses likely. The absence of evident modifications in inferior vena cava flow patterns suggests normal cardiac hemodynamics. In particular, the finding of values of percentage of reverse flow similar to those of fetuses matched for gestational age but of larger size is consistent with a normal development of the ventricular filling properties in spite of the reduced growth.

Both the selection criteria and pregnancy outcome strongly suggest that the growth defect of the fetuses of groups 2 and 3 resulted from uteroplacental insufficiency. These fetuses showed an increase of peak velocities and time velocity integral systolic-to-diastolic ratios associated with an increased percentage of reverse flow. These modifications are similar to those induced by hypoxia in instrumented lamb fetuses[7] and confirm recent observations in growth retarded human fetuses characterized by absent end-diastolic velocities in the umbilical artery.[3] These changes are compatible with an impaired cardiac function that may be secondary to different reasons, including a decreased ventricular compliance,[13] a higher end-diastolic ventricular pressure caused by an increased afterload consequent to the increased peripheral and placental resistances,[14, 15] or a reduced right myocardial contractility.[16, 17] As a consequence of these abnormal flow patterns, the return of blood from the placenta to the heart is impaired, thus further reducing the supply of oxygen and nutrients to fetal tissues. This may explain our data on the different outcome of fetuses with similar modifications in arterial vascular districts but different venous flow abnormalities. This hypothesis is supported by the data of Indik et al.[13] who found a different trend in perinatal mortality in fetuses with absent end-diastolic flow in the umbilical artery in the presence of pulsation in the umbilical vein, a situation closely associated with increased value of percentage of reverse flow.

It is noteworthy that in our series an increased reverse flow is present also in approximately 27% of the SGA fetuses of group 2 (presence of end-diastolic velocities in the umbilical artery). In spite of the absence of any differences in pulsatility index values from various different arterial vascular beds or in fetal smallness these fetuses had a higher incidence of antepartum late heart rate decelerations, a shorter time interval between the recordings and delivery, and lower umbilical artery pH values. These findings suggest that among growth-retarded fetuses with uteroplacental insufficiency the study of inferior vena cava velocity waveforms might allow better identification than that with conventional measurements in arterial peripheral vessels, a subgroup of fetuses with a more severe degree of fetal compromise.

The lack of correlation between Doppler-measured arterial resistances and inferior vena cava flow patterns suggests that the degree of cardiac dysfunction necessary to yield abnormal venous patterns in the inferior vena cava is not directly related to arterial vascular resistances but may depend on different factors such as the temporal duration of the hemodynamic alterations. Our longitudinal study allowed us to validate this concept. In spite of the minimal changes in the pulsatility index values in arterial vascular districts there was a progressive deterioration of the inferior vena cava indices considered in the time interval elapsing between

the diagnosis to the onset of abnormal fetal heart rate patterns suggestive of abnormal fetal oxygenation.[19] These findings are compatible with the fall of both cardiac output and aortic and pulmonary peak velocities described in the growth-retarded fetuses longitudinally followed.[20] All these changes may be expressions of the same phenomenon, namely, a progressive deterioration of cardiac function.

Moreover, the advantages of recording inferior vena cava velocity waveforms must be pointed out. Unlike echocardiographic measurements, the indices of inferior vena cava used are angle independent and do not need calculation of vessel area, thus allowing more reproducible and easier recordings.

In conclusion, abnormal flow patterns in the inferior vena cava are present in SGA fetuses as a result of uteroplacental insufficiency. These patterns are unrelated to the abnormalities present in Doppler-measured vascular resistances in fetal arterial vascular beds. However, the noninvasive nature of the human fetal model does not allow for full clarification of the underlying pathophysiologic condition in these abnormal venous velocity patterns. The presence of increased reverse flow in the inferior vena cava in spite of the presence of end-diastolic flow in the umbilical artey may be a warning sign. In fetuses followed up longitudinally until the onset of spontaneous late heart rate decelerations a progressive deviation from the norm of inferior vena cava flow patterns was evidenced, thus suggesting their potential role in the longitudinal monitoring of growth-retarded fetuses. However, an evaluation by means of decision-making techniques (e.g., analysis of receiver-operator characteristic curves) on a larger number of fetuses is required before inferior vena cava flow is used as a clinical test.

Diathermy loop excision in the management of cervical intraepithelial neoplasia: Diagnosis and treatment in one procedure

Karel G.G. Keijser, MD,[a] Peter Kenemans, MD,[b] Petronella H.Th.H. van der Zanden,[a] Charles P.T. Schijf, MD,[a] G. Peter Vooijs, MD,[c] and Rune Rolland, MD[a]

Nijmegen and Amsterdam, The Netherlands

OBJECTIVE: Diathermy loop excision was performed as a new diagnostic-treatment procedure in patients with cervical cytologic diagnoses consistent with an epithelial abnormality.

STUDY DESIGN: A total of 424 patients with cervical cytologic diagnoses consistent with an epithelial abnormality, but macroscopically or colposcopically not consistent with invasive carcinoma, were subjected to diathermy loop excision to diagnose and treat cervical lesions in one procedure.

RESULTS: The diagnostic accuracy rate was 99%. In patients with histologically confirmed grade 3 cervical intraepithelial neoplasia, pretreatment cytologic diagnosis and subsequent histopathologic diagnosis corresponded in 73% of cases. In 91% of all patients the diathermy loop excision was sufficient for complete treatment. Cervical morphologic findings after treatment allowed adequate cytologic follow-up. There was no evidence that diathermy loop excision influenced fertility or pregnancy outcome.

CONCLUSION: Diathermy loop excision is a reliable, well-tolerated, inexpensive, and efficient technique for the management of cervical intraepithelial neoplasia. This outpatient procedure is especially recommended in younger patients, because diathermy loop excision preserves the function of the cervix. (AM J OBSTET GYNECOL 1992;166:1281-7.)

Key words: Diathermy loop, cervical intraepithelial neoplasia, follow-up

Screening for cervical cancer is carried out worldwide by means of cervical smears. Problems associated with cytologic screening of the uterine cervix have been the subject of many studies. In his review article Koss[1] stated that, in spite of the known failures in the screening system, the cervical smear is still an effective tool for cancer detection. The natural history of cervical intraepithelial neoplasia remains a controversial subject. It is generally accepted that grades 1 and 2 cervical intraepithelial neoplasia will either regress, persist or progress to grade 3 cervical intraepithelial neoplasia. Even after several years of persistence, a substantial percentage of grade 3 cervical intraepithelial neoplasia will ultimately progress to invasive carcinoma.[2] Consequently, all patients with grade 3 cervical intraepithelial neoplasia lesions require treatment, and in addition many surgeons in this field also treat grades 1 and 2 cervical intraepithelial neoplasia lesions. In the case of an abnormal cervical smear further investigation is necessary. In general, the management of these patients consists of destruction or complete excision of the entire transformation zone after invasive carcinoma has been excluded by means of histopathologic examination of one or more biopsy specimens.

The colposcopically directed punch biopsy has been accepted as a valuable technique for achieving an accurate histologic diagnosis. Cartier[3] introduced the use of the diathermy loop excision for cervical biopsy and suggested its use as a local (excision) treatment procedure. Prendiville et al.[4] showed diathermy loop excision to be a better technique for performing cervical biopsies when compared with the punch biopsy technique. In 1982 De Haan and Kenemans[5] were among the first to use the diathermy loop as a therapeutic procedure in which the complete transformation zone in patients with cervical intraepithelial neoplasia was removed after a histologic diagnosis was established on the basis of biopsy material.

Histologic examination of the whole transformation zone, obtained by diathermy loop excision, enables the pathologist to make a more accurate diagnosis than is usually possible when only biopsy material is examined. We therefore abandoned the preceding biopsy procedure in our clinic, making use of the diathermy loop excision as a combined diagnostic and therapeutic approach for the management of cervical intraepithelial neoplasia.

This study analyzed diagnostic accuracy, morbidity, and treatment results of diathermy loop excision during long-term follow-up in a large number of patients with cytologic diagnosis suspicious for cervical intraepithelial neoplasia lesions.

Material and methods

Patients. From January 1982 to January 1988, all patients with cytologic diagnoses consistent with cervical intraepithelial neoplasia lesions or (micro)invasive carcinoma were managed by diathermy loop excision of the entire transformation zone without a prior diagnostic biopsy. All patients underwent colposcopic examination before treatment. Diathermy loop excision was then performed even if the transformation zone was not fully visible. The only exclusion criterion for diathermy loop excision was suspicion of invasive carcinoma on colposcopic examination. A total of 424 patients were entered in this study, the majority being ≤35 years old (Table I).

The cytologic findings before treatment are presented in Table II. In 20 patients smears were suspect for slight dysplasia, moderate dysplasia was suspected in 72 patients and severe dysplasia in 168 patients. Furthermore, smears were consistent with carcinoma in situ in 153 patients, and 11 patients had smears suspicious of (micro)invasive carcinoma. Pretreatment cytologic findings were compared with final histopathologic diagnoses (Table II).

Technique. After colposcopy, paracervical tissue was infiltrated with 10 ml of 1% prilocaine hydrochloride in each side. A rectangular stainless steel diathermy loop excision (0.2 mm, Fig. 1) was chosen according to the extent of the lesion and connected to a diathermy machine (Valleylab SSE 2). After application of iodine solution the entire iodine-negative area was removed. There was no standard procedure for the excision, but usually the posterior lip was removed before the anterior lip and eventually, depending on the extent of the lesion at colposcopic evaluation, a central and sometimes a deeper central excision was performed. If necessary, hemostasis was obtained by coagulation with the loop or a ball electrode. All tissue obtained at diathermy loop excision was submitted for histopathologic examination.

Follow-up. Completeness of treatment was assessed by follow-up cervical smears. Follow-up ranged from 3 to 8 years with a median follow-up of 4.8 years. Within 2 years after treatment, three or more adequate smears were obtained from 375 patients. After three normal smears, a control cytologic examination was usually performed every year. When an abnormal smear was found during follow-up, the diagnostic and treatment procedure was started again. Immediate and long-term morbidity and the influence of diathermy loop excision on fertility and pregnancy outcome were recorded.

Results

Tissue obtained by diathermy loop excision allowed histopathologic examination. In experienced hands the diathermy loop does not cause significant artifacts that interfere with microscopic evaluation in the excised tissue. The pathologist was unable to make a diagnosis in only two of 424 cases, as a result of the complete absence of epithelium in the excised specimens. In all other cases a histologic diagnosis was established. All analyses were made without any revision of the histologic diagnosis. The final histopathologic diagnosis was compared with pretreatment cytologic diagnosis (Table II). In 178 of the cases studied (42%), the histologic diagnosis correlated entirely with pretreatment cytologic diagnosis. In 73 of 424 (17%) cases the final histopathologic diagnosis was more severe, and in 173 patients (41%) it was less severe than the initial pretreatment cytological diagnosis. Combining severe dysplasia and carcinoma in situ (grade 3 cervical intraepithelial neoplasia), the pretreatment cytologic diagnosis and histopathologic diagnosis corresponded in 73% of the cases. Smears were diagnosed as being suspicious for invasive cancer in 11 patients. Invasive cancer was confirmed histologically in only two of these patients. On the other hand, invasive carcinoma was histopathologically diagnosed in 14 patients, whereas the pretreatment cytologic diagnosis was not suspicious for invasive carcinoma. In 12 of these patients only microinvasive carcinoma was diagnosed.

For all patients, with the exception of five, diathermy loop excision unequivocally provided a definitive diagnosis on the basis of the most severe histopathologic abnormality present in that patient. Of the five patients

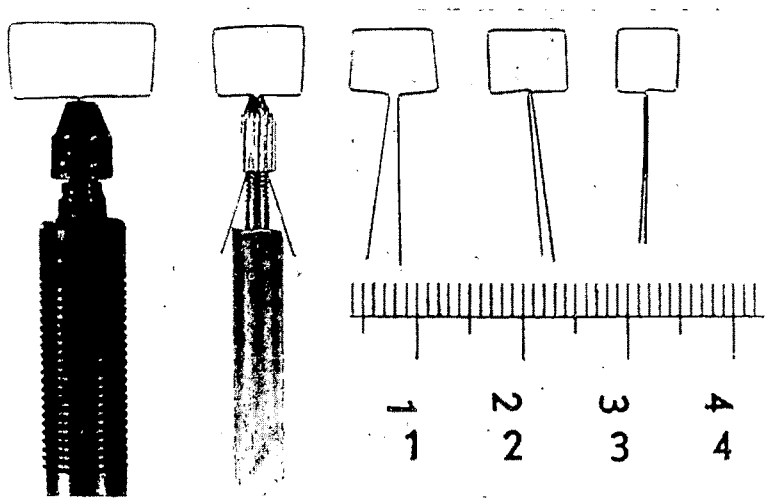

Fig. 1. Stainless steel diathermy loops as used in this study.

mentioned, the final histopathologic diagnosis in four cases was not grade 2 cervical intraepithelial neoplasia (as found with the initial diathermy loop excision) but grade 3 cervical intraepithelial neoplasia (as found with a second treatment procedure), and in one case the final histopathologic diagnosis was grade 2 instead of grade 1 cervical intraepithelial neoplasia (Table III). The diagnostic accuracy rate in this group was 99%.

Follow-up cervical smears were taken to evaluate the efficacy of the diathermy loop excision. On analysis of the first year of follow-up, 11 patients (2.6%) were lost to follow-up, 18 (4.2%) had undergone a second treatment before a first follow-up smear was taken, and 395 (93.2%) had one or more cytologic control examinations. In 285 of these 395 patients (72%) the first smear during follow-up was normal, and in 110 cases (28%) the first smear demonstrated cytologic findings consistent with mild dysplasia or a more severe lesion. Of these 110 patients with an abnormal first follow-up smear, 63 (57%) smears returned to normal within 1 year, without further intervention. When the first control smear was classified as consistent with mild dysplasia (n = 42), consecutive smears showed a return to normal in 88% of the patients in the first year. In the group of 285 patients showing no abnormalities in a first follow-up smear, subsequent smears showed abnormal findings in 25 patients. Cytologic findings were consistent with mild dysplasia in nine patients, moderate dysplasia in seven, and severe dysplasia carcinoma in situ in nine (Table IV).

The overall cure rate of primary diathermy loop excision, defined as the achievement of normal cytologic findings without further treatment, was 81% in this study. In 63 patients (15%) a second and in eight patients (2%) a third treatment procedure was performed after persistent abnormal cytologic findings. A diathermy loop excision was performed in 41 cases, conization in 10 cases, and hysterectomy in 20 cases (Table V). This means that 30 of 395 patients with cytologic control examinations had hysterectomy or conization as an ultimate treatment, resulting in an overall cure rate of 92% after diathermy loop excision in these patients.

Immediate and long-term morbidity. Hemorrhage can be a complicating factor during the healing process. In 32 cases (8%) secondary hemorrhage occurred during the first week after treatment. In 21 of these cases additional coagulation was necessary.

The healing process takes approximately 2 to 3 weeks. During this period, in which patients are discouraged from engaging in sexual intercourse, vaginal discharge is frequently seen. However, a manifest cervicitis after diathermy loop excision was seen in only one patient.

Stenosis of the cervical canal after primary diathermy loop excision was seen in four cases (1%). In the group of patients with a second diathermy loop excision a further case of stenosis was observed. Of these five patients, four were >45 years old.

Ninety-six patients tried to achieve pregnancy after diathermy loop excision and 78 succeeded. The total number of pregnancies in these patients was 96. Seventeen of these pregnancies resulted in abnormal labor (Table VI).

Infertility after diathermy loop excision was seen in 18 patients. Of these, 11 patients were already known to have fertility problems before treatment. Of the remaining seven patients, an unfavorable cervical milieu was part of the fertility problem in two patients. In these

two patients cervical function was not known before treatment. An unfavorable cervical milieu was never the only fertility problem.

Comment

This study shows that diathermy loop excision is a combined diagnostic and therapeutic procedure for the management of patients with abnormal cervical cytologic findings. Patients in our study were selected on the basis of an abnormal smear. In the majority of the cases studied (58%), pretreatment cytologic findings did not correspond with the final histopathologic diagnosis. However, as has been reported by Van Nagell et al.[6] there was a good correlation between cytologic and histologic findings (73%) in this group with high-grade intraepithelial neoplasia (grade 3).

The management of cervical intraepithelial neoplasia lesions so far has involved many treatment modalities,[7-13] comprising excision techniques such as cold knife conization, electroconization, laserconization, diathermy loop excision, and hysterectomy or tissue destructive techniques such as cryocoagulation, electrocoagulation, and laser vaporization. In general, patients with cytologic findings suspicious for cervical intraepithelial neoplasia lesions will undergo colposcopy to confirm the abnormality of the epithelium and the extent of the lesion. Excision techniques can be performed after colposcopy without prior biopsy. When the transformation zone is not fully visible, many surgeons will opt for cold knife conization. The disadvantages of this technique are the need for hospital admission and general anesthesia.

Laser conization is a time-consuming procedure and the laser apparatus is very expensive. In addition, destructive techniques are restricted to patients with a satisfactory colposcopic examination, after exclusion of invasive carcinoma by prior biopsies.

Diathermy loop excision is a combined diagnostic and therapeutic procedure in which the entire transformation zone is removed. It can be performed with ease

Cesarean section (failure to progress)	1

in an outpatient clinic in the same session as colposcopy. It takes only about 1 to 2 minutes for the excision and 2 to 3 minutes to obtain hemostasis, and in addition the equipment is inexpensive.

Histopathologic examination of the tissue encompassing the entire transformation zone avoids missing or undergrading cervical intraepithelial neoplasia lesions, and (micro)invasive carcinoma. Pathologists raise the objection that the completeness of treatment cannot be assessed because of the loss of defined tissue margins. However, to evaluate the completeness of treatment, the finding of a cytologic abnormality has proved to be a more useful prognostic indicator than the histologic examination of excision margins.[14] Residual disease with crypt involvement, situated at the surface after healing, is probably due to the open excision margins as a consequence of the diathermy loop excision technique. Therefore residual disease is easily detected by follow-up cytologic testing. Furthermore, in contrast to cold knife conization or cryocoagulation, residual disease will not be hidden by cicatrization.

The excellent cervical morphologic features after diathermy loop excision, with optimal localization of the neosquamocolumnar junction, (NSCJ) permit good

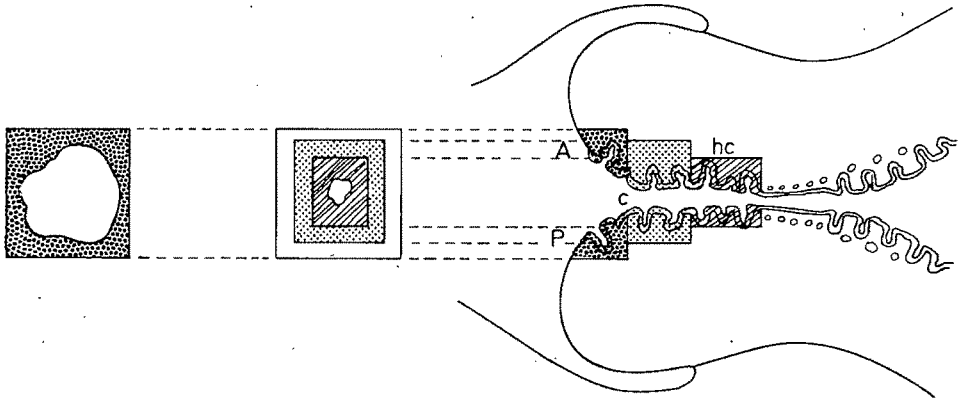

Fig. 2. Schematic sectional view of cervix uteri. *A*, Anterior lip; *P*, posterior lip; *c*, central; *hc*, high central.

cytologic follow-up. The follow-up smear should always contain a combination of columnar and squamous epithelial cells. A control smear that contains only squamous epithelial cells is inadequate, and the smear must be repeated. The fact that 63 of 110 (57%) abnormal first follow-up smears returned to normal at subsequent cytologic examination without additional intervention justifies an expectant approach to low-grade cervical intraepithelial neoplasia diagnosed in follow-up smears. When cytologic findings consistent with severe dysplasia or carcinoma in situ (grade 3 cervical intraepithelial neoplasia) occur in follow-up smears, then further investigation is necessary.

The overall success rate of diathermy loop excision in this study was 92%. This result was in the same range as that obtained with both destructive techniques, cryocoagulation and laser vaporization.[9-11] However, these destructive techniques are restricted to patients without endocervical extension of the lesion, a group of patients that has the lowest risk of residual disease. Furthermore, the success rate was found to be in the same range as that obtained with laser conization.[10, 11] Compared with the laser technique, diathermy loop excision is less time-consuming, cheaper, and much easier to perform.

In this study we used rectangular loops. The advantage of this loop is that the control of the depth of the excision is much better. The actual excision itself, however, may be insufficient. Excision margins should extend 3 to 5 mm beyond the margins of the transformation zone, both on the ectocervix and in the endocervical canal. When the lesion extends into the endocervical canal and is not entirely visible, we recommend the removal of an additional deeper central part (Fig. 2). Because diathermy loops in various forms are commercially available, many surgeons may choose a semicircular loop and perform a conelike excision. Even so, when a semicircular loop is used, the excision of an additional central part to prevent undertreatment is advisable.

Hemorrhage is a well-known complication of cold knife conization. Before coagulation was introduced, sutures were used to stop bleeding. Nowadays the use of hemostatic sutures in excision techniques is rare. To perform laser conization, local anesthesia in combination with a vasoconstrictor is necessary. With a diathermy loop, hemostasis can be well controlled even without vasopressin. In 8% of patients secondary hemorrhage was seen during the healing process. In most of the cases additional coagulation was necessary. Secondary hemorrhage is a well-known complication of cold knife conization, but with laser conization secondary hemorrhage is very rare.[10, 11]

An increasing number of women of reproductive age are being subjected to a local treatment procedure that may alter the cervical environment and, in so doing, could theoretically affect cervical competence. Our results demonstrate that diathermy loop excision does not affect fertility and pregnancy outcome. However, individual exceptions may be caused by extreme scarring or reduction of cervical mass. This agrees with the results obtained with other treatment modalities, as reported by others.[9, 10, 13, 15, 16]

The results of this large series of patients warranted the conclusion that diathermy loop excision offers a good alternative in the management of cervical intraepithelial neoplasia lesions. It has all the advantages of an outpatient treatment, is just as effective as all other techniques, and requires much less expensive equipment. The excellent anatomic status of the cervix after diathermy loop excision permits good cytologic follow-up, which has been shown to be sufficiently reliable to detect residual disease.

We are very grateful to L. Massuger, MD, for scientific support.

Fetal polycythemia and thrombocytopenia in pregnancies complicated by maternal diabetes mellitus

Douglas R. Salvesen, MD, Michael J. Brudenell, MD, and Kypros H. Nicolaides, MD

London, England

In 40 pregnancies complicated by maternal diabetes mellitus umbilical venous blood was obtained by cordocentesis within 24 hours of elective delivery at 36 to 40 weeks' gestation. The mean fetal hematocrit was significantly higher and the mean platelet count significantly lower than the corresponding values of our reference ranges. Furthermore, blood gas analysis demonstrated these fetuses to be normoxemic but acidemic. The degree of fetal acidemia was significantly associated with both maternal and fetal blood glucose concentrations. The fetal hematologic indices were significantly related to the maternal glycosylated hemoglobin percentage but not to the degree of fetal acidemia or to the maternal or fetal blood glucose concentration at the time of cordocentesis. Fetal acidemia, polycythemia, and thrombocytopenia may contribute to the increased incidence of late unexplained intrauterine deaths in pregnancies complicated by maternal diabetes mellitus. (Am J Obstet Gynecol 1992;166:1287-92.)

There is a well-recognized association between maternal diabetes mellitus and late unexplained fetal death.[1] Although the cause remains uncertain, there is indirect evidence implicating fetal hypoxia. Thus in diabetic pregnancies the incidence of abnormal fetal heart rate patterns in labor and low Apgar scores at delivery is increased.[2, 3] Furthermore, analysis of cord blood at delivery has demonstrated decreased Po_2 and

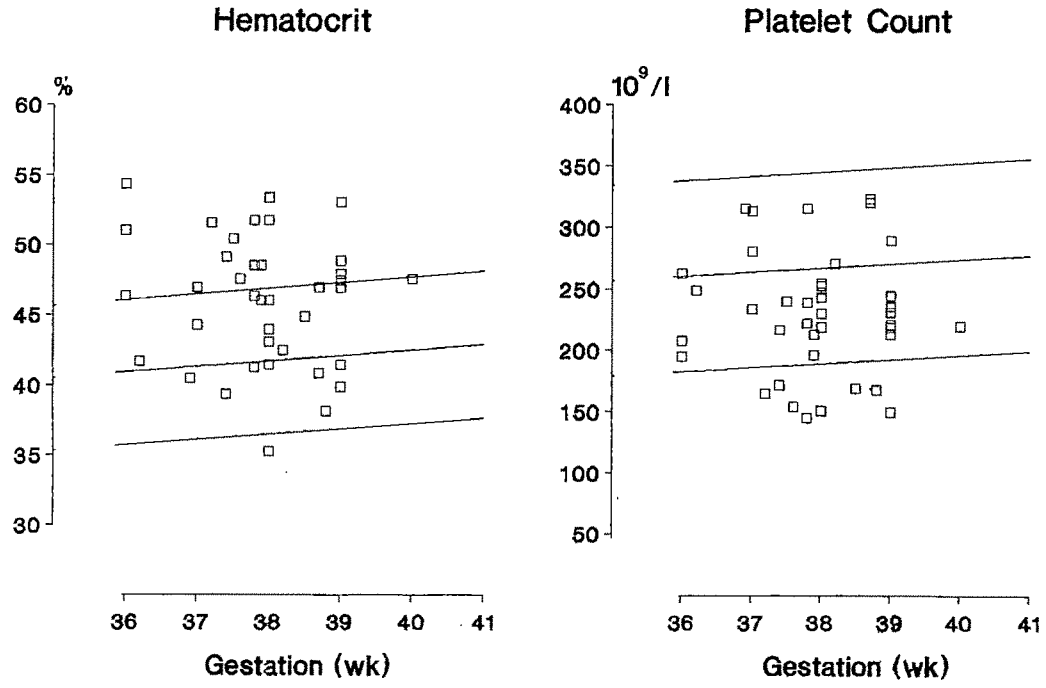

Fig. 1. Hematocrit and platelet count plotted on appropriate reference range (mean with 95th and 5th percentiles) with gestation.

pH and increased erythropoietin concentration in association with neonatal polycythemia.[4-6] More recently Bradley et al.[7] measured fetal blood gases at cordocentesis in pregnancies complicated by maternal diabetes mellitus and reported that the mean pH was significantly lower than in nondiabetic controls.

The aim of the current study was to investigate the relationship between possible hematologic changes in fetuses of diabetic mothers and maternal diabetic control and fetal blood gases. Fetal blood samples were obtained by cordocentesis rather than at delivery because the process of birth itself may influence the measured parameters.

Patients and methods

Umbilical venous blood was obtained by cordocentesis up to 24 hours before delivery at 36 to 40 weeks' gestation in 40 women with established (n = 32) or gestational (n = 8) diabetes. A maternal venous blood sample was also taken from the antecubital fossa before cordocentesis. In each case gestational age was established from the menstrual history (n = 32) or by an early ultrasonographic scan in those with uncertain dates (n = 8). The patients were recruited from our diabetic antenatal clinic. Before giving their written consent, the patients were counseled that the procedure was experimental and that the results would not give any direct benefit to their current pregnancy. The study was approved by our hospital ethics committee.

All patients were insulin treated, and according to the White classification 23 belonged to group B, 15 to group C, and two to group D.[8] None of the patients had chronic hypertension or preeclampsia. The pregnancies were managed expectantly; according to our current policy and in consultation with individual patients, elective delivery was undertaken at 36 to 40 weeks' gestation, depending on fetal growth and well-being and previous obstetric and medical history. In 24 cases the mode of delivery was by elective cesarean section for previous cesarean section (n = 12), suspected macrosomia (n = 5), breech presentation (n = 4), congenital abnormality of the maternal pelvis (n = 1), poor obstetric history (n = 1), and maternal ischemic heart disease (n = 1). Induction of labor was undertaken in 16 patients; 11 had vaginal deliveries and five had emergency cesarean section because of suspected cephalopelvic disproportion (n = 1) or abnormal intrapartum fetal heart rate patterns (n = 4).

Cordocentesis was performed without fetal paralysis or maternal fasting or sedation, and all procedures were uncomplicated.[9] Fetal blood was collected into a heparinized syringe (350 μl) for blood gas analysis (Radiometer ABL330, Copenhagen) and for measurement of whole blood glucose (YSI 23A, Yellow Springs Instruments Co., Yellow Springs, Ohio). Fetal blood was also collected in tubes containing ethylenediametetraacetic acid (500 μl) for measurement of hematocrit and platelet and total white blood cell counts (Coulter

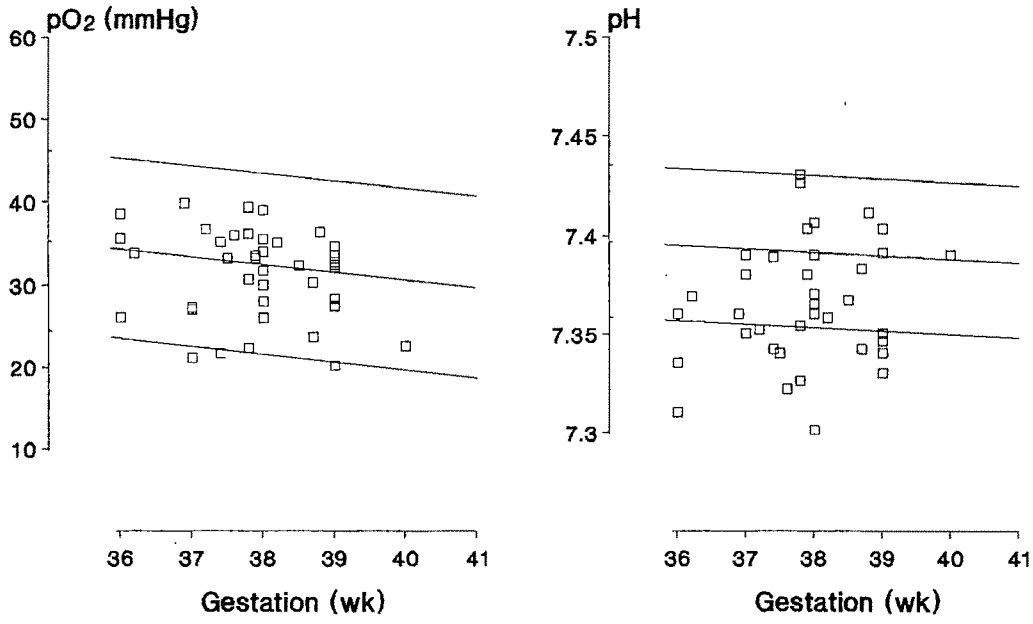

Fig. 2. Umbilical venous blood Po_2 and pH plotted on appropriate reference range (mean with 95th and 5th percentiles) with gestation.

S-Plus, Coulter Electronics, Luton, United Kingdom). Kleihauer testing confirmed that all samples contained only fetal blood. Blood films were stained with Jenner's giemsa on an automatic processing machine, and the corrected white blood cell count and number of erythroblasts per 100 white blood cells were determined. At the time of cordocentesis a maternal blood sample was taken from the antecubital fossa for the measurement of whole blood glucose concentration as described and the glycosylated hemoglobin percentage by electroimmunodiffusion (Corning scanner, Corning, Halstead, United Kingdom).

Umbilical venous blood was also collected at delivery from 26 of the patients; there were 14 elective cesarean sections with patients under epidural ($n = 7$) or general ($n = 7$) anesthesia, five emergency cesarean sections, and seven vaginal deliveries. The cord was double clamped immediately after delivery, and an umbilical venous blood sample was taken in heparinized syringes for measurement of pH.

Unpaired Student t tests were applied to investigate if the measured parameters differed from the reference ranges for normal pregnancies. For birth weight and maternal glycosylated hemoglobin percentage, published ranges were used.[9, 10] For the others our reference ranges with gestation were used: hematocrit 2.425 + 0.396 × weeks, SD 0.0211, $n = 311$; platelet count 129.5 + 3.62 × weeks, SD 46.74, $n = 311$; corrected white blood cell count 0.152 + 0.104 × weeks − 0.004 × weeks^2 + 0.0005 × weeks^3, SD 0.0283, $n = 311$; umbilical venous blood pH 7.47 − 0.0023 × weeks, SD 0.0306, $n = 268$; and umbilical venous blood Po_2 62.305 − 0.811 × weeks, SD 7.512, $n = 268$. The patient selection and methods used to establish these ranges were as previously detailed.[11-13] By comparison with the normal ranges, all hematologic parameters, blood gas values and birth weights for the diabetic pregnancies were expressed as the number of standard deviations by which individual values differed from the normal mean for gestation (Δ-value). Regression analysis was then used to define any significant associations between hematologic Δ-values and blood gas Δ-values, birth weight Δ-values, maternal glycosylated hemoglobin percentage, and fetal and maternal blood glucose concentrations. Regression analysis was also used to define the significance of associations in blood gas data at cordocentesis and delivery.

Results

In the 40 diabetic pregnancies the mean fetal hematocrit was significantly higher than the normal mean for gestation (Fig. 1; mean difference 1.014 SD, SE 0.236, $t = 4.29$, $p < 0.0001$). In contrast, mean platelet count was significantly lower (Fig. 1; mean difference −0.802 SD, SE 0.168, $t = -4.77$, $p < 0.0001$). The mean white blood cell count was not significantly different (mean difference −0.273 SD, SE −0.271, $t = -1.01$).

The fetal blood pH was significantly lower (Fig. 2; mean difference −1.087 SD, SE 0.192, $t = -5.67$, $p < 0.0001$), whereas the Po_2 was not significantly different from the appropriate normal mean for gestation

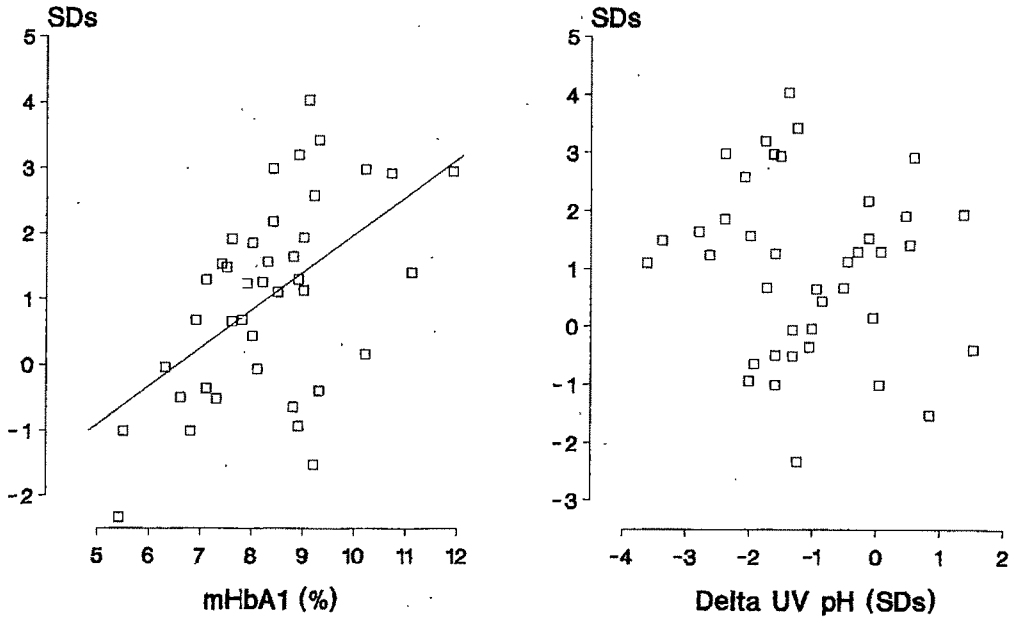

Fig. 3. Relationship between Δ-value of fetal hematocrit and maternal glycosylated hemoglobin percentage *(mHbA$_1$)* and between Δ-value of fetal hematocrit and Δ-value of umbilical venous pH *(Delta UV pH)*.

Table I. Association between fetal hematocrit, platelet count, blood gas values (pH and Po_2), fetal umbilical venous glucose concentration, fetal birth weight, and maternal glycosylated hemoglobin percentage

	Δ-Value of hematocrit (r)	*Δ-Value of platelet count (r)*
Δ-Value of platelet count	−0.358*	
Δ-Value of pH	−0.133	−0.132
Δ-Value of Po_2	−0.032	−0.285
Δ-Value of birth weight	0.171	0.015
Umbilical venous glucose concentration	0.091	−0.002
Maternal glycosylated hemoglobin	0.537†	−0.348*

All values except maternal glycosylated hemoglobin and umbilical venous glucose concentration were expressed as difference from normal mean for gestation in standard deviations (Δ-values).

*$p < 0.05$.

†$p < 0.001$.

(Fig. 2; mean difference −0.201 SD, SE 0.128, $t = -1.57$). The maternal glycosylated hemoglobin percentage and birth weight were significantly higher than the appropriate normal means for gestation (mean difference 1.382 SD, SE 0.309, $t = 6.10$, $p < 0.0001$ and mean difference 1.007 SD, SE 0.206, $t = 4.89$, $p < 0.0001$, respectively).

The associations between Δ-values for fetal hematologic findings and those for fetal blood gases, fetal blood glucose concentration, fetal size, and maternal glycosylated hemoglobin are shown in Table I. There were significant associations between Δ-values for fetal hematocrit and platelet count. In addition, Δ-values for both fetal hematocrit (Fig. 3) and platelet count (Fig. 4) were significantly associated with maternal glycosylated hemoglobin but not with fetal blood gas values, fetal glucose concentration, or Δ-value for fetal weight. There was a significant association between both the maternal and the fetal blood glucose concentration and Δ-value for fetal pH ($r = -0.449$, $p < 0.01$ and $r = -0.397$, $p = 0<0.05$, respectively).

In the 26 patients in whom umbilical venous blood pH was measured both at cordocentesis and at delivery there was no significant association between the predelivery and postdelivery data ($r = 0.15$). In all but one case the pH after delivery was lower than the pH at cordocentesis, and the greatest decrease was in those patients with vaginal deliveries (Fig. 5).

All infants were healthy at birth and normal anatomy was confirmed. There was no clinical evidence of any thromboses in the neonatal period.

Comment

This study has demonstrated that in pregnancies complicated by maternal diabetes mellitus some fetuses are acidemic, polycythemic, thrombocytopenic, and macrosomic. Furthermore, there are significant asso-

ciations between the degree of polycythemia and thrombocytopenia and maternal glycemic control, as reflected in increased maternal glycosylated hemoglobin percentage. The lack of a significant association in the umbilical venous blood pH between results at cordocentesis and those at delivery demonstrates that fetal biochemistry may be altered by the process of birth.

The finding of acidemia in a substantial proportion of the fetuses provides support for the concept that altered acid-base status may contribute to the increased

incidence of late unexplained stillbirths in pregnancies complicated by maternal diabetes. The significant association between both maternal and fetal glucose concentrations and the degree of fetal acidemia suggests that the latter may be the consequence of increased metabolic rate, which is a result of fetal hyperglycemia. The data provide an extension to the previous observations of Bradley et al.,[7] who reported that fetal acidemia was not associated with hypoxemia. Chronic hyperglycemia in pregnant sheep results in increased fetal glycolysis, accumulation of lactate, and fall in pH.[14, 15] Fetal anaerobic glycolysis may occur in the presence of hyperglycemia, because animal studies have shown there is reduced capacity for oxidative metabolism and gluconeogenesis and low pyruvate dehydrogenase activity in intrauterine life.[16] Furthermore, minor elevations in fetal blood glucose are associated with acidemia in the absence of hypoxemia.[15]

In the neonatal period polycythemia is most commonly defined as a hematocrit >65%, and the reported incidence in infants of diabetic mothers is 16% to 34%.[6, 17] This wide range may be partly a consequence of the different methods used in these studies, including gestational age, mode of delivery, time of cord clamping, and the site and time of sampling. In our study polycythemia is defined as a hematocrit >95th percentile for gestational age, and the incidence was 40%. The significant association of fetal hematocrit with maternal glycosylated hemoglobin percentage, but not with fetal or maternal glucose concentration at cordocentesis, implies that long-term rather than short-term glycemic control is important in the development of polycythemia. Pedersen's theory[18] suggests that maternal hyperglycemia causes fetal hyperglycemia and hyperinsulinemia. Insulin may stimulate erythropoiesis either through a direct effect on the marrow[19] or indirectly through increased metabolic rate, tissue hypoxia, and consequent erythropoietin release.

Fetal thrombocytopenia, like polycythemia, was associated with maternal glycosylated hemoglobin percentage but not with maternal or fetal blood glucose concentration at the time of cordocentesis. The most likely cause of the mild fetal thrombocytopenia is increased platelet consumption, because previous studies have demonstrated that in infants of diabetic mothers there is increased platelet aggregation.[20] The abnormalities in infants of diabetic mothers include increased platelet endoperoxide formation and decreased vascular prostacyclin production.[20, 21]

The combination of fetal polycythemia (with consequent hyperviscocity) and increased platelet aggregation could offer an explanation for the increased incidence of intravascular thromboses in infants of diabetic mothers.[22, 23] Indeed, it could lead to intrauterine thrombotic episodes, offering an alternative to acidemia as the underlying cause for late unexplained intrauterine deaths. In a postmortem study of 4000 neonatal deaths the incidence of venous thromboses in infants of diabetic mothers was 15.8% compared with an incidence of <1% in the remaining cases.[23] Furthermore in the infants of diabetic mothers the thrombi showed more frequent organization and calcification, suggesting intrauterine formation.

In pregnancies complicated by maternal diabetes the incidence of unexplained stillbirths has been reduced with intense multidisciplinary antenatal care; however, it remains a well-recognized complication of diabetic pregnancy.[24] Fetal acidemia and increased tendency for intravascular thromboses, either individually or in combination, could be the underlying cause.

Actocardiotocographic monitoring of triplets during vaginal delivery

Jim van Eyck, PhD,[a] and Birgit Arabin, PhD[b]
Zwolle, The Netherlands, and Berlin, Germany

A case is reported in which fetal monitoring during vaginal delivery of triplets was performed with the MT 430 actocardiotocograph. This method provides optimal monitoring of multiple pregnancies because the fetal heart rate tracings of three fetuses, together with recordings of fetal movements and uterine contractions, can be visualized on one display. (AM J OBSTET GYNECOL 1992;166:1293-4.)

Key words: Actocardiotocograph, triplets, fetal monitoring, delivery

The numbers of multiple births have increased dramatically in many countries as a result of the widespread use of ovulation-inducing agents and assisted reproductive technologies. For example, in the United States the number of twins and triplets—higher-order births increased by 33% and 101%, respectively, during the decade between 1978 and 1988. Similar increases have been observed in the United Kingdom and Germany.

At present, the mode of delivery of triplets is controversial. If the vaginal route is chosen, along with other requirements it is mandatory to obtain optimal monitoring of all three fetuses. In 1984 Maeda[1] described the actocardiotocograph, which permits registration of the fetal heart rate (FHR) tracing in combination with fetal movements and uterine contractions.[1] Recently an advanced model, the MT430 actocardiotocograph (Toitu Co., Ltd., Tokyo, Japan), was developed for use with multiple pregnancies, and first attempts were made to define fetal behavior in twins.[2]

Case report

A 30-year-old woman, para 1, became pregnant with triplets after in vitro fertilization. At 14 weeks' gestation elective cerclage was performed. At 26 weeks the patient was admitted for bed rest because of increasing mechanical discomfort. Periodic ultrasonographic examinations revealed three fetuses, in vertex position, having normal growth. External FHR tracings, and Doppler flow measurements of the umbilical artery were normal in all three fetuses. At 35 weeks the cerclage suture was removed, after which labor began. After artificial rupture of the membranes of the first amniotic sac, a scalp electrode was placed on the fetal head, followed by insertion of a catheter for measurement of intrauterine pressure. The second and third fetuses were externally monitored with respect to FHR and fetal movement. Five hours after amniorrhexis full dilatation was present. Shortly thereafter the three infants were born in vertex position during a 15-minute period. Throughout labor and delivery, FHR tracings of all three fetuses, together with recordings of uterine contractions and fetal movement of the two externally

monitored fetuses, were visualized on one display panel (Fig. 1). Birth weights of the infants were 2000, 2180, and 1680 gm, respectively, and umbilical cord pH was 7.35, 7.31, and 7.39, respectively.

Comment

Fetal monitoring of triplets generally is a time-consuming effort, necessitating the use of a variety of equipment. When several machines are used or recordings are performed in sequence, there is a risk of monitoring one or more fetuses twice, leaving one or even two fetuses unexamined. The MT430 actocardiotocograph is a small, portable device capable of collecting and displaying all FHR tracings simultaneously along with the intensity of uterine contractions and the movement patterns of two of the three fetuses.

The two external FHR and fetal movement tracings are registered by only two separate transducers with a carrier frequency of 1.1 MHz and an intensity of <1.1 mW/cm^2. During vaginal delivery of triplets, the third FHR tracing is internal. Uterine contractions can be monitored either externally or internally. The FHR is documented according to the principle of autocorrelation at a range of 50 to 240 beats/min. Fetal movements are documented simultaneously by the same transducer in an analog manner. Thus the density of the spikes reflects the frequency of fetal movement, and the amplitude reflects the velocity of fetal movement.

The use of the MT430 actocardiotocograph provides optimal fetal monitoring during vaginal delivery of triplets.

Abnormal 1,25-dihydroxyvitamin D metabolism in preeclampsia

Phyllis August, MD, Beth Marcaccio, MD, Joseph M. Gertner, MD, Maurice L. Druzin, MD, Lawrence M. Resnick, MD, and John H. Laragh, MD
New York, New York

We previously reported that preeclampsia is associated with hypocalciuria (N Engl J Med 1987;316:715). The purpose of this study was to determine whether alterations in calcium regulatory hormones are present in preeclampsia and, if so, whether they are responsible for hypocalciuria. Thirty-two pregnant women were studied in the second and third trimesters of pregnancy (11 women with preeclampsia, nine with chronic hypertension, and 12 normotensive women). 1,25-Dihydroxyvitamin D, C-terminal parathyroid hormone, ionized calcium, and urinary calcium excretion were measured. 1,25-Dihydroxyvitamin D was significantly lower in the women with preeclampsia in the third trimester when the disease developed (37.8 ± 15 pg/ml) than in women with chronic hypertension (75 ± 15 pg/ml, $p < 0.05$) and normal women (65 ± 10 pg/ml, $p < 0.05$). Parathyroid hormone was higher, but not significantly, in those with preeclampsia. Ionized calcium was not significantly different among the three groups. Urinary calcium excretion was abnormally low for pregnancy (<50 mg/24 hr) in all but one women with preeclampsia. We conclude that 1,25-dihydroxyvitamin D is reduced in preeclampsia and may lead to hypocalciuria by causing decreased intestinal absorption of calcium, stimulation of parathyroid hormone, and increased distal renal tubular resorption of calcium. The cause of reduced 1,25-dihydroxyvitamin D in preeclampsia is unknown and may be due to either diminished renal or placental production of the hormone. (Am J Obstet Gynecol 1992;166:1295-9.)

Key words: Preeclampsia, calcium metabolism, 1,25-dihydroxyvitamin D, hypocalciuria

Alterations in calcium metabolism have been reported in human essential hypertension and experimental animal models of hypertension and have been implicated in the pathogenesis of elevated blood pressure.[1-3] It has also been suggested recently that calcium regulation may be abnormal in preeclampsia, a hypertensive disorder unique to pregnancy.

We previously reported that preeclampsia is associated with hypocalciuria,[4] an observation subsequently confirmed by other investigators.[5-7] Moreover, we suggested that measurement of urinary excretion of calcium may be useful in distinguishing preeclampsia from other forms of gestational hypertension. We hypothesized that hypocalciuria is due to increased renal tubular resorption of calcium rather than decreased filtered load, because fractional excretion of calcium was significantly lower in women with preeclampsia.

We report here an investigation of the hormonal basis for hypocalciuria. We determined the concentrations of 1,25-dihydroxyvitamin D, parathyroid hormone, and serum and urinary calcium in women with preeclampsia and compared them with those of normotensive pregnant women and women with chronic hypertension. It was considered important to study 1,25-dihydroxyvitamin D levels because either a low level (e.g., primary deficiency leading to decreased serum calcium, increased parathyroid hormone, and increased renal tubular resorption of calcium) or a high level (e.g., primary calcium deficiency leading to increased parathyroid hormone, increased tubular resorption of calcium, and increased renal 1α-hydroxylase activity) might be associated with hypocalciuria, and possible therapeutic options might be different.

We report here that 1,25-dihydroxyvitamin D levels are significantly lower in preeclampsia and parathyroid hormone is higher, compared with levels in normal and chronically hypertensive pregnant women.

Methods

Thirty-two pregnant women were studied during the second and third trimesters of pregnancy. Preeclamptic women were recruited from consecutively hospitalized patients with the disease. An attempt was made to minimize the uncertainty in the diagnosis of preeclampsia;

Table I. Clinical characteristics of study patients (third trimester)

	Normal (n = 9)	*Chronic hypertension (n = 9)*	*Preeclampsia (n = 9)*
Maternal age (yr)	29 ± 4.2	32 ± 2.8	26 ± 6*
Gestational age (wk)	33.9 ± 2.7	35 ± 0.8	31.2 ± 3.7
Parity			
Nulliparous	8	4	7
Multiparous	1	5	2
Race

White	7	7	4
Other	2	0	1

*$p < 0.02$, compared with chronic hypertension.

Table II. Blood pressure and laboratory data on study patients (third trimester)

	Normal (n = 9)	*Chronic hypertension (n = 9)*	*Preeclampsia (n = 9)*
Maximal mean arterial pressure (mm Hg)	83 ± 5	102 ± 10*	131 ± 17†
Urine protein (mg/24 hr)	93 ± 47	181 ± 56	3631 ± 4114‡
Serum uric acid (mg/dl)	5.3 ± 1.07	4.03 ± 1.06	8.4 ± 1.5§
Serum creatinine (mg/dl)	0.8 ± 0.06	0.7 ± 0.11	1.1 ± 0.39‡
Platelet count ($\times 10^5$)	250 ± 80	244 ± 64	144 ± 115

Mean arterial pressure calculated as: (Systolic pressure plus 2 × Diastolic pressure) divided by 3.

*$p < 0.02$, compared with normal pregnancy.

†$p < 0.001$, compared with normal pregnancy and chronic hypertension.

‡$p < 0.05$, compared with chronic hypertension.

§$p < 0.01$, compared with normal pregnancy and chronic hypertension.

therefore patients with mild disease were excluded. Women with chronic hypertension were recruited from the office practices of the investigators. Normotensive women were healthy pregnant volunteers recruited from the employees of The New York Hospital. Patients with preexisting intrinsic renal disease were excluded. None of the subjects was receiving diuretics during the study. All patients were taking prenatal vitamins that contained 200 to 600 mg of calcium carbonate per tablet. All patients were eating an unrestricted diet either at home or, in the case of the preeclamptic women, in the hospital. Hypertension in pregnancy was defined as the presence of a blood pressure of 140/90 mm Hg or a rise of 30 mm Hg in systolic pressure or 15 mm Hg in diastolic pressure. Preeclampsia was defined as hypertension associated with excretion of >300 mg of urinary protein per 24 hours (or >2+ in a single voided specimen) or abnormal liver function tests and decreased platelet count.[8] Chronic hypertension was defined as the presence of a documented blood pressure of >140/90 mm Hg before pregnancy. None of the patients with chronic hypertension had superimposed preeclampsia.

Venous blood was collected from pregnant women in the second and third trimesters. Twenty-four–hour urine collections were obtained at the same times, except when a woman with severe preeclampsia was delivered <24 hours after admission to the hospital. Serum ionized calcium was measured with a calcium ion electrode apparatus in serum collected under anaerobic conditions. 1,25-Dihydroxyvitamin D was measured after chromatography on Sep-Pak C_{18} columns by a microassay with receptors from calf thymus.[9] Parathyroid hormone was measured by a radioimmunoassay with an antibody that recognizes the C-terminal fragment (Smith Kline & French, Van Nuys, Calif.). Serum levels of uric acid and creatinine were assayed by multichannel automated techniques. Urinary creatinine levels were determined by an autoanalyzer, and urinary calcium was measured by atomic absorption spectroscopy. Urinary protein was measured by nephelometry after precipitation with trichloroacetic acid.[10]

Mean arterial pressure was calculated as follows: (Systolic pressure + 2 × Diastolic pressure) divided by 3. Analysis of variance and the Student–Neuman-Keuls tests were used to determine differences between normal, chronic hypertensive, and preeclamptic women. All p values are two-tailed.

Results

The study population ($n = 32$) consisted of 11 women with preeclampsia (two were delivered in the second trimester, nine in the third), nine women with chronic hypertension (all were studied in both second

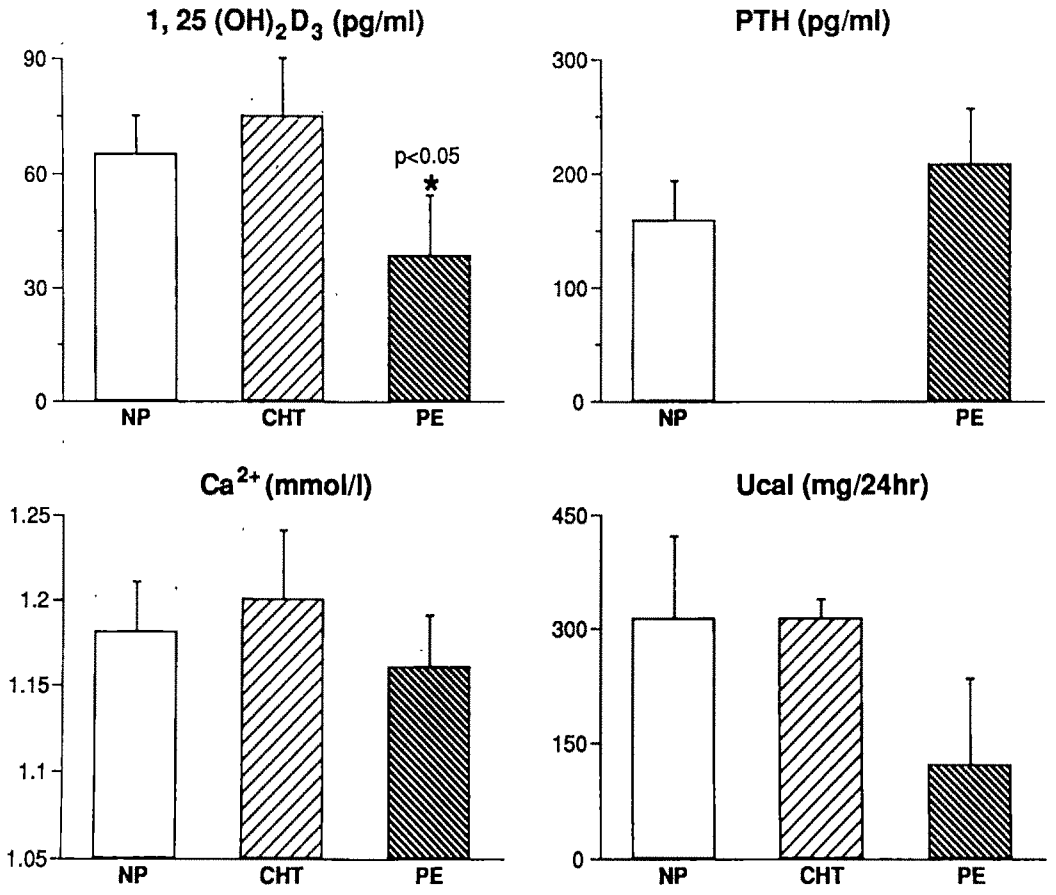

Fig. 1. Mean ± SD 1,25-dihydroxyvitamin D_3 *(1,25 [OH]$_2$ D_3)* C-terminal parathyroid hormone *(PTH)*, serum ionized calcium *(Ca^{2+})*, and urine calcium excretion *(U_{Cal})* in third-trimester pregnant women. *NP*, Normotensive women (n = 9); *CHT*, chronic hypertensive women (n = 9); *PE*, preeclamptic women (n = 9).

and third trimesters), and 12 normotensive women (three were studied in the second trimester alone, three in both second and third trimesters, and six only in the third trimester). It was considered important to present the data for patients studied at a similar gestational age; therefore the data obtained from patients in the third trimester were analyzed separately from those obtained in the second trimester. Because of the smaller number of patients with preeclampsia in the second trimester, only data from third-trimester patients are presented in the tables and figures.

The clinical characteristics of the third-trimester patients are shown in Table I. Two of the nine preeclamptic women were multiparous but had new mates for the pregnancies in this study. As shown in Table II, the preeclamptic women had significant hypertension, proteinuria, hyperuricemia, azotemia, and low platelet counts.

Fig. 1 compares 1,25-dihydroxyvitamin D, parathyroid hormone, and serum and urinary calcium concentrations found in preeclamptic, normotensive, and chronic hypertensive pregnancies in the third trimester. 1,25-Dihydroxyvitamin D levels were significantly lower in women with preeclampsia when compared with either chronic hypertensive or normotensive women. The mean ± SD concentration in the nine preeclamptic women studied in the third trimester was 37.8 ± 15.5 pg/ml, compared with 75 ± 15 pg/ml in the chronic hypertensive, and 65 ± 10 pg/ml in the normal pregnant women ($p < 0.05$). Parathyroid hormone levels tended to be higher in women with preeclampsia than in normotensive women; however, the differences did not reach statistical significance. One woman with severe preeclampsia, hypocalciuria, and low levels of 1,25-dihydroxyvitamin D had an extraordinarily high level of parathyroid hormone (132,000 pg/ml), which normalized postpartum. The basis for this marked pregnancy-related increase is not clear. It is possible that altered renal function, which is present in preeclampsia, contributed to diminished clearance of the carboxyterminal fragment of the parathyroid hormone molecule. This patient was excluded from the

statistical analysis of the parathyroid hormone levels. Urinary calcium excretion was abnormally low (<50 mg/24 hr) in all except one preeclamptic woman in whom 24-hour urine samples were obtained.

The two preeclamptic women who had severe disease and were delivered in the second trimester also had lower 1,25-dihydroxyvitamin D levels (21 and 41 pg/ml). The mean ± SD was 62 ± 27 pg/ml in the six second trimester normal women and 59 ± 8 pg/ml in the nine chronic hypertensive women studied at a similar gestational age. Thus these second-trimester preeclamptic women clearly had abnormally low 1,25-dihydroxyvitamin D levels. Parathyroid hormone was elevated (350 pg/ml) in one of the two women. Urine calcium excretion could only be measured in one (the other was delivered immediately), and it was extremely low (34 mg/24 hr), compared with 234 ± 43 mg/24 hr in normotensive second-trimester women and 201 ± 24 mg/24 hr in women with chronic hypertension.

Although several patients with preeclampsia had low ionized calcium levels, they were not significantly different from the other groups. One woman with severe preeclampsia had a markedly decreased creatinine clearance (41 ml/min, serum creatinine 2.0). In the remaining 10 preeclamptic women serum creatinine clearance in eight of these women was 116 ± 52 ml/min. Therefore in most cases hypocalciuria was out of proportion to the reduction in glomerular filtration rate.

Comment

We originally demonstrated that hypocalciuria is a feature of preeclampsia and may be useful in its diagnosis. In the current study we have extended our investigations of calcium regulation in hypertensive pregnancy. We report for the first time that 1,25-dihydroxyvitamin D levels are significantly lower in preeclamptic women than in normotensive and chronically hypertensive women.

Our finding of lower 1,25-dihydroxyvitamin D levels in preeclampsia and the tendency for parathyroid hormone levels to be higher supports the hypothesis that these alterations in calcium regulatory hormones may be in part responsible for hypocalciuria in this disorder. Indeed, parathyroid hormone–mediated, enhanced distal tubular resorption of calcium is thought to play a role in the hypocalciuria associated with renal insufficiency.[11] More recently, in the rabbit it has been shown that parathyroid hormone causes increased transport of luminal calcium into the cells of the connecting tubule, resulting in reduced urinary excretion of calcium.[12] In this study the increased parathyroid hormone levels observed in many of the preeclamptic women did not result in a statistically significant higher level for the group. However, elevated parathyroid hormone levels in women with preeclampsia have been reported previously by others.[5, 13]

In our earlier study[4] 1,25-dihydroxyvitamin D was measured in 30 of the 40 patients, and although the levels appeared lower in preeclamptic women, the differences between normal, chronic hypertensive, and preeclamptic women were not statistically significant. However, in the earlier study the patients had mild preeclampsia, in contrast to the patients studied in this report who had severe disease. Moreover, in our earlier study patients with transient hypertension and chronic hypertension with superimposed preeclampsia were included in the analysis and may have masked the differences.

In normal pregnancy elevations of 1,25-dihydroxyvitamin D have been consistently observed.[14-17] Although there is still controversy regarding whether parathyroid hormone levels are elevated or decreased during normal pregnancy, more recent studies measuring intact hormone reported lower levels.[18] In this study C-terminal, rather than intact, parathyroid hormone was measured. The concentration of C-terminal parathyroid hormone is determined in part by changes in glomerular filtration rate, whereas intact parathyroid hormone levels best reflect parathyroid gland secretory activity. Because alterations in renal function and alterations in calcium metabolism are present in preeclampsia, it is not yet clear which assay is more relevant to the pathophysiologic characteristics of the disease. We would have preferred to measure intact and C-terminal parathyroid hormone in our patients; however, the intact assay was not available for this study.

The factors responsible for elevated 1,25-dihydroxyvitamin D levels in normal pregnancy are not well understood; therefore at the present time we can only speculate as to the basis for reduced levels in preeclampsia. There is evidence that placental 1α-hydroxylase contributes to the elevated 1,25-dihydroxyvitamin D levels in normal pregnancy.[19, 20] Because preeclampsia, especially when it is severe, is characterized by suboptimal placental function, perhaps as a result of ischemia,[21] the lower 1,25-dihydroxyvitamin D levels may reflect placental dysfunction caused by reduced uteroplacental blood flow. Alternatively, abnormal proximal tubular function, resulting in diminished renal 1α-hydroxylation may be responsible for reduced levels of 1,25-dihydroxyvitamin D.

We have previously reported that nonpregnant individuals with low-renin essential hypertension have elevated 1,25-dihydroxyvitamin D levels.[22] Although normal pregnancy is associated with marked stimulation of the renin-angiotensin system, when preeclampsia develops, plasma renin activity is suppressed.[23] The reason for the differential profile of 1,25-dihydroxyvitamin D in these two conditions may be that in low-

renin essential hypertension the elevation in 1,25-dihydroxyvitamin D is a physiologic response to low ionized calcium and parathyroid hormone–mediated stimulation of renal 1α-hydroxylase, whereas in preeclampsia decreased 1,25-dihydroxyvitamin D is the primary disturbance.

Finally, it is worth mentioning that several institutions are investigating the ability of calcium supplementation to prevent preeclampsia, as a result of reports that dietary calcium deficiency predisposes women to development of preeclampsia.[24] However, if dietary calcium deficiency leads to preeclampsia, then this might be expected to cause elevated parathyroid hormone and stimulation of renal 1,25-dihydroxyvitamin D production. Our observation that 1,25-dihydroxyvitamin D is lower in preeclampsia raises the possibility that decreased intestinal absorption of calcium (as a secondary result of decreased vitamin D) rather than decreased dietary intake may be involved in the pathogenesis of preeclampsia. However, in the setting of reduced 1,25-dihydroxyvitamin D, dietary calcium deficiency might be expected to lead to more profound calcium depletion. Therefore the outcome of calcium supplementation trials (for the prevention of preeclampsia) will be of great interest.

Long-term sequelae of acute pelvic inflammatory disease

A retrospective cohort study

Sharon Safrin, MD,[a, b] Julius Schachter, PhD,[b, c] Donna Dahrouge, MPH,[d] and Richard L. Sweet, MD[d]

San Francisco, California

OBJECTIVE: Our objective was to prospectively assess the frequency and predictors of long-term sequelae of acute pelvic inflammatory disease.

STUDY DESIGN: We performed a retrospective cohort study of 140 women admitted for treatment of pelvic inflammatory disease to San Francisco General Hospital in 1985, locating and interviewing 51 women by telephone a median of 37 months later.

RESULTS: Twelve (24%) women had pelvic pain for 6 months or more after hospitalization, 22 (43%) had subsequent episode(s) of pelvic inflammatory disease, and 40% were involuntarily infertile. A history of pelvic inflammatory disease prior to admission was associated with infertility ($p = 0.05$), chronic pelvic pain ($p = 0.03$), and pelvic inflammatory disease subsequent to hospitalization ($p = 0.06$). Longer duration of abdominopelvic pain before admission and younger age at the time of first sexual intercourse were associated with both infertility ($p = 0.02$, $p = 0.04$) and subsequent pelvic inflammatory disease ($p = 0.04$, $p = 0.0008$).

CONCLUSIONS: Further studies are needed to more accurately assess the incidence and predictors of long-term sequelae of pelvic inflammatory disease. A reduction in adverse outcome will require more stringent efforts at education and reduction of risk-taking behaviors. (AM J OBSTET GYNECOL 1992;166: 1300-5.)

Key words: pelvic inflammatory disease, infertility, chronic abdominal pain

Approximately 750,000 women in the United States require treatment for acute pelvic inflammatory disease annually.[1] In addition to the morbidity and economic costs associated with acute illness, the risk of long-term sequelae of this infection appears to be substantial. A prospective Swedish study of 415 women with laparoscopically verified acute salpingitis reported frequencies of 21.2% involuntary infertility, 18% chronic abdominal pain, and 4.1% ectopic pregnancy after an episode of acute pelvic inflammatory disease.[2] Seroepidemiologic case-control studies have further implicated acute pelvic inflammatory disease, particularly that caused by *Chlamydia trachomatis*, as a precursor of both infertility[3-5] and ectopic pregnancy.[6-9]

Given a more heterogeneous population and a possible difference in distribution of etiologic pathogens in women in the United States with acute pelvic inflammatory disease as compared with that in the Swedish studies by Westrom,[2] we sought to assess the frequency of long-term sequelae prospectively. We extracted baseline clinical and microbiologic data from review of the medical charts of all women with the discharge diagnosis of acute pelvic inflammatory disease at San Francisco General Hospital in 1985. We then attempted long-term follow-up of all women by telephone interview in 1988 and 1989, to assess the frequency and predictors of long-term sequelae of acute pelvic inflammatory disease.

Methods

All women with the discharge diagnosis of pelvic inflammatory disease, salpingitis, or tuboovarian abscess on the gynecologic, family practice, medical, or pediatric services at San Francisco General Hospital in the year 1985 were identified by computerized retrieval. All women older than 32 at the time of admission were excluded from further analysis, to avoid bias in the assessment of the outcome of infertility.

Data concerning demographic characteristics, birthing and contraceptive histories, clinical presentation at the time of admission, microbiologic pathogens, and complications during follow-up were extracted by review of the medical record. Cervical, endometrial, tubal, or peritoneal specimens were cultured for *Neis-*

From the Departments of Medicine,[a] Epidemiology and Biostatistics,[b] Laboratory Medicine,[c] and Obstetrics, Gynecology and Reproductive Sciences,[d] University of California, San Francisco.

seria gonorrhoeae, C. trachomatis, Mycoplasma hominis, Ureaplasma urealyticum, and facultative aerobic and anaerobic organisms, as previously described.[10]

From April 1988 to March 1989 repeated attempts were made to locate all women in the sample. Current addresses were sought through use of the hospital computer, and through formal requests to the Sexually Transmitted Diseases Control Morbidity Registry of the San Francisco Department of Public Health, the Division of Motor Vehicles, and the United States Post Office. We sent initial and follow-up letters to all available addresses, with a self-addressed, stamped postcard enclosed for reply. In addition, all women for whom a telephone number was available were contacted and asked to participate. Attempts to reach the potential participant at each referred phone number were made until met with inability to locate her or refusal to be interviewed; the interviewer's name and phone number were offered so that the participant might be able to call at a time most convenient for her.

The telephone interview was a standardized questionnaire administered by a single individual (S.S.). Long-term sequelae of pelvic inflammatory disease were defined as follows: (1) involuntary infertility, which was failure of conception after a period of at least 1 year of unprotected intercourse (women who were rendered surgically infertile after the index episode of acute pelvic inflammatory disease and those who regularly used contraception to prevent pregnancy were excluded from this component of the analysis), (2) ectopic pregnancy, (3) chronic pelvic pain, which was pain in the pelvic area lasting >6 months and beginning after the index episode of pelvic inflammatory disease, (4) recurrent pelvic inflammatory disease, which was a treated episode of acute pelvic inflammatory disease that occurred after the index episode in 1985. Definitions of involuntary infertility and chronic abdominal pain were the same as those used in previous studies.[2, 11]

Continuous variables are described with mean and standard deviation and analyzed with the two-tailed *t* test or logistic regression. Categoric variables were compared with two-tailed Fisher's exact or χ^2 tests. Relative risk estimates are followed by 95% confidence intervals. All analyses were done with the SAS statistical program (SAS Institute Inc., Cary, N.C.).

The study received approval from the Institutional Review Board of the University of California, San Francisco.

Results

Baseline characteristics. Chart review was performed for each of 140 hospitalized women; baseline characteristics are described in Table I. A history of pelvic inflammatory disease was found in 55 (39%) women; 27 reported one prior episode and 28 had had two or more prior episodes. A history of prior pelvic inflammatory disease, prior gonococcal cervical infection, or prior chlamydial cervical infection was elicited in 77 (55%) women. Fourteen women (10%) admitted

to exchanging in sex for money and 28 (20%) to past or current intravenous drug usage.

Tuboovarian abscess was diagnosed in 16% of women by ultrasonography or physical examination and was associated with a longer mean duration of abdominopelvic pain before the initiation of antimicrobial therapy (8.6 vs 5.2 days, $p = 0.03$). Antimicrobial therapy of acute pelvic inflammatory disease consisted of cefoxitin with doxycyline in 91 women (65%), clindamycin with tobramycin in 31 (22%), and other agents (SCH 34343, ampicillin-sulbactam, mezlocillin) in 18 (13%).

Microbiology. Cervical, endometrial, or tubal specimens yielded *N. gonorrhoeae* in 50% of 127 women and *C. trachomatis* in 27% of 118 women; rate of coinfection was 14% in 113 women tested (Table I). Microbiologic pathogen was not associated with age, method of birth control, presence of cervical mucopus on examination, history of irregular bleeding, or tuboovarian abscess. No differences in temperature or white blood cell count on admission, duration of abdominal pain before initiation of therapy, or number of days of hospitalization were detectable in women with gonococcal infection compared with those having chlamydial infection. Mean erythrocyte sedimentation rate was highest in women with chlamydial infection (52.4 mm/hr) and lowest in women with neither *N. gonorrhoeae* nor *C. trachomatis* isolated (27.4 mm/hr) ($p = 0.0002$, Kruskal-Wallis test).

Endometrial cultures were obtained in 97 women: *Gardnerella vaginalis* was isolated in 50 (52%) and *Bacteroides* species in 30 (31%) (*Bacteroides bivius* 21, *Bacteroides disiens* 6). Peptostreptococci were found in 28 women, peptococci in 17, and mobiluncus in four. Aerobic organisms included lactobacilli (44 women), coagulase-negative staphylococci (24), coryneform bacteria (23), and streptococci (viridans group 14, group D 11, group B 10). *Haemophilus influenzae* was isolated from one specimen. Endometrial cultures were sterile in six women.

Frequency and predictors of long-term sequelae in interviewed women. Fifty-one women (36.5%) were interviewed by telephone at a median interval of 37.5 months after the index episode of pelvic inflammatory disease (range 29 to 49 months). Two women refused to be interviewed and 87 could not be located.

Twenty-five women (48%) had a subsequent pregnancy; of these two (2.4%) had ectopic pregnancies at 17 and 30 months after the index pelvic inflammatory disease episode, respectively.

Seventeen of 42 interviewed women (40%) who were neither surgically infertile nor regularly using contraception met the definition for involuntary infertility. Women with an episode of pelvic inflammatory disease before the 1985 admission were more likely to be infertile (59% vs 27%, $p = 0.05$), as were those with a younger age at the time of first sexual intercourse (mean 14.3 vs 16 years, $p = 0.04$) (Table II). Mean number of prior episodes of pelvic inflammatory disease was 1.3 in infertile women versus 0.6 in others ($p = 0.05$). Women who had ≥2 days of abdominal pain before admission had a twofold increased risk of infertility when compared with women who had pain of <2 days' duration (54% vs 14%, $p = 0.02$). In a multivariate model only a history of pelvic inflammatory disease before the index 1985 episode remained independently associated with involuntary infertility ($p = 0.05$) (Table II).

Twelve of 51 women (24%) had chronic pelvic pain (see Methods). Nine had sought medical attention for the pain; four of these had been treated with antibiotics, two used nonsteroidal antiinflammatory agents, and six took no medication for relief. Four had gynecologic surgical procedures possibly related to their complaints of pain (laparoscopy 2, salpingectomy–salpingostomy–lysis of adhesions 1, percutaneous drainage of ovarian cyst 1). A history of pelvic inflammatory disease before 1985 was associated with occurrence of chronic pain after the index episode ($p = 0.03$) (Table II); no other associations with chronic pain were detectable.

Twenty-two women (43%) had one or more episodes of pelvic inflammatory disease subsequent to the 1985 index episode, occurring at a median of 2.1 months after admission (range 1 to 40). Women with subsequent episodes of pelvic inflammatory disease tended to be younger at the time of first sexual intercourse (mean 13.9 vs 16.4 years, $p = 0.0008$) and had a longer duration of abdominal pain before presentation for admission in the index 1985 episode (mean 8.9 vs 4.3 days, $p = 0.04$). Mean number of pelvic inflammatory disease episodes before 1985 was higher in women with subsequent episodes (1.4 vs 0.4, $p = 0.008$). Risk of subsequent pelvic inflammatory disease was 30% in women with no history of PID, 50% in those with one prior episode, and 72% in those with two or more past episodes. A history of pelvic inflammatory disease before the index 1985 episode ($p = 0.02$), age at the time of first sexual intercourse ($p = 0.01$), and duration of abdominal pain before admission ($p = 0.04$) retained an independent association with recurrence of pelvic inflammatory disease (Table II). The long-term sequelae of infertility and recurrent pelvic inflammatory disease were associated with one another ($p = 0.05$).

Method of contraception, microbial pathogen, presence of tuboovarian abscess, mean temperature, white blood cell count, erythrocyte sedimentation rate, and type of antimicrobial agent administered did not show an association with occurrence of long-term sequelae by univariate analysis in the cohort; however, when stratified for first versus recurrent episode of acute pel-

Table II. Frequency and predictors of long-term sequelae of acute pelvic inflammatory disease

Sequela	*Frequency (No. and %)*	*Risk factor*	*Univariate analysis*		*Multivariate analysis p value*
			p	*Relative risk and 95% confidence interval*	
Involuntary infertility	17/42 (40%)	History of pelvic inflammatory disease	0.05	1.8 (1.0-3.3)	0.05
		Age at time of first sex	0.04		0.39
		≥2 Days of pain before theapy	0.02	2.0 (1.1-3.6)	0.07
Chronic pelvic pain	12/51 (24%)	History of pelvic inflammatory disease	0.03	1.5 (1.0-2.2)	
Pelvic inflammatory disease after index episode	22/51 (43%)	History of pelvic inflammatory disease	0.06	1.7 (0.9-3.1)	0.02
		Mean No. of days of pain before therapy	0.04	—	0.04
		Age at time of first sex	0.0008	—	0.01
Ectopic pregnancy	2/51 (2.4%)	*			

*Risk analysis not performed because of small numbers involved.

vic inflammatory disease, presence of a positive culture for *C. trachomatis* was significantly associated with involuntary infertility in women in whom the index episode was the first ($p = 0.008$, relative risk = 2.5, 95% confidence interval = 1.0 to 6.2) but not in women who were having a recurrent episode of pelvic inflammatory disease at the time of admission in 1985 ($p = 0.5$). Also, presence of coinfection with *N. gonorrhoeae* and *C. trachomatis* in women with first-episode pelvic inflammatory disease in 1985 was associated with subsequent occurrence of episodes ($p = 0.007$, relative risk = 1.4, 95% confidence interval = 1.0 to 2.3) but not in women with a history of pelvic inflammatory disease at the time of admission in 1985 ($p = 0.4$).

Long-term sequelae in women not interviewed. Comparison of the 51 women who were interviewed by telephone with the remaining 89 women in the cohort revealed no significant differences in baseline characteristics, except that a greater proportion of interviewed women had a tuboovarian abscess during the index admission (25.5% vs 12.4%, $p = 0.05$) (Table I). However, tuboovarian abscess was not associated with occurrence of long-term sequelae in this analysis (infertility $p = 0.5$, chronic pain $p = 0.7$, recurrent pelvic inflammatory disease $p = 0.7$).

Review of the medical record revealed that six of the 89 women not interviewed had sought medical evaluation for inability to conceive. Nineteen had pregnancies subsequent to the index diagnosis of acute pelvic inflammatory disease; one of them was an ectopic pregnancy occurring 13 months later. Ten women were evaluated for complaints of chronic pelvic pain ≥6 months after the index episode, and 19 had recurrent episodes of acute pelvic inflammatory disease after the index admission.

Frequency estimates of long-term sequelae derived solely from chart review data were substantially lower than those derived from telephone interview: infertility 5% vs 40% ($p = 0.0001$), ectopic pregnancy 0.7% vs 2.4% ($p = 0.24$), chronic pelvic pain 13% vs 24% ($p = 0.05$), recurrent pelvic inflammatory disease 27% vs 43% ($p = 0.01$).

Comment

We assessed the frequency of long-term sequelae over a period of 1825 woman months after hospitalization for acute pelvic inflammatory disease in 1985 (median interval after hospitalization 37.5 months). Interpretation of results is limited by an incomplete rate of follow-up in the cohort, failure to confirm the clinical diagnosis of pelvic inflammatory disease laparoscopically, and lack of a control group. Nevertheless, the high frequency of long-term sequelae in this population of women (infertility 41%, chronic pain 43%, recurrent episodes 24%, and ectopic pregnancy 2.4%) in spite of hospitalization for close observation and parenteral antimicrobial therapy suggests that further research is necessary to document the actual incidence of these sequelae and to further our understanding in methods of prevention.

We demonstrated the absence of significant differences in baseline characteristics in women who were interviewed as compared with those not able to be located (Table I), other than the presence of tuboovarian abscess at the time of admission in a greater proportion of women not interviewed. Use of record review alone, however, in women not available for interview yielded markedly lower estimates of long-term sequelae than in those interviewed (infertility 5%, chronic pelvic pain 13%, recurrent pelvic inflammatory disease 27%, ectopic pregnancy 0.7%). These differences may reflect an underestimation of long-term sequelae by record review because of the failure of women in this population to seek evaluation for symptoms or their use of alternative medical centers. Alternatively, overestimation of the frequency of long-term sequelae may have occurred in interviewed women as a result of reporting bias. Therefore our estimates may be construed as minimum (in the noninterviewed group) and maximum (in those interviewed) estimates of long-term sequelae, to be more precisely delineated by careful prospective studies.

We found that a history of one or more episodes of pelvic inflammatory disease before the index admission, present in 41% of patients at the time of admission, was associated with higher rates of involuntary infertility, chronic pelvic pain, and recurrent episodes of pelvic inflammatory disease after the 1985 admission. This is in agreement with previous studies.[2, 12] In spite of interaction with the health care system in 55% of interviewed women for prior pelvic inflammatory disease or gonococcal or chlamydial cervical infection, more than two thirds of women were not using contraception at the time of admission and a maximum of 9% were using barrier contraception. Factors other than prior pelvic inflammatory disease that were associated with an increased frequency of long-term sequelae, such as a younger age at the time of first sexual intercourse and a longer duration of pelvic pain before presentation for medical evaluation, suggest that further progress in the prevention of sequelae must be accomplished through educational efforts directed at reduction of risk-taking behaviors and early recognition of symptoms by the patient.

We were unable in this study to definitively establish the temporal sequence of infertility and acute pelvic inflammatory disease or to establish the cause of involuntary infertility as tubal. In addition, some authors have suggested that the definition of infertility used in this and previous[2, 11, 12] studies may overinflate estimates of frequency.[4] Nevertheless, the correlation of number of episodes of pelvic inflammatory disease with infertility helps to validate the strong link between acute pelvic inflammatory disease and involuntary infertility identified in previous prospective studies.[2, 11, 15-18] Also, the greater frequency of infertility in women with ≥2 days of abdominal pain before initiation of therapy agrees with previous animal[19] and human[20] studies that emphasize the importance of early therapy in the prevention of irreversible tubal damage, a condition that occurs in approximately 2 million women in the United States.[21]

The occurrence of ectopic pregnancy in two interviewed women after the index episode of pelvic inflammatory disease constitutes an increased frequency eightfold over that observed in women of reproductive age in the general United States population.[22] This, combined with evidence from several cohort[2, 23] and case-control[6, 8, 9] studies suggesting a link between salpingitis and subsequent ectopic pregnancies, is evidence that intensification of efforts to prevent pelvic inflammatory disease will help to prevent a condition associated with substantial mortality in this country.[22]

Previous studies have suggested that nongonococcal salpingitis, particularly that caused by *C. trachomatis*, may incur a greater impairment in subsequent fertility than other microbiologic pathogens produce.[2-5, 15, 24] Although we were unable to detect an association of microbiologic pathogen with reproductive outcome in the total group of women studied, we did find an association of chlamydial infection with subsequent infertility in those women in whom the 1985 episode of pelvic inflammatory disease was reported to be the first. It is conceivable therefore that this relationship was masked in the entire interviewed group as a result of confounding by recurrent episodes of tubal damage caused by infection or other strong risk factors. Unfortunately, it does not appear from this or prior studies[25] that alterations in antibiotic therapy to empirically treat chlamydial infection will have a major impact on fertility prognosis.

Future studies should seek to confirm our frequency estimates and to better identify predictors of the long-term sequelae of acute pelvic inflammatory disease. Ideally, laparoscopic or endometrial biopsy confirmation of the clinical diagnosis of acute pelvic inflammatory disease, thorough sampling of involved sites to determine microbiology, and aggressive attempts at optimal follow-up over a long-term period should occur. Consent for enrollment into long-term cohort studies must be obtained at the outset, and intensive educational counseling as to recognized risk factors for recurrence and the importance of initiation of early therapy for symptoms of recurrent pelvic inflammatory disease should be instituted. In addition, exclusion of women who are involuntarily infertile at the time of admission for acute pelvic inflammatory disease is necessary. Extensive investigation of the etiology of infertility identified during follow-up, in both patients (e.g., by assessment of tubal morphologic characteristics by

hysterosalpingogram or laparoscopic dye insufflation) and their partners, should be performed to more accurately define the incidence and natural history of the reproductive sequelae of acute pelvic inflammatory disease.

We thank Richard Juster for statistical assistance, Gail Bolan for research and consultative assistance, Nancy Padian for review of the manuscript, and Marilyn Robbie for consultation in study design.

LETTERS TO THE EDITORS

Infarction of placental chorioangioma and associated regression of hydrops fetalis

To the Editors: I read the article by Chazotte et al. (Chazotte C, Girz B, Koenigsberg M, Cohen WR. Spontaneous infarction of placental chorioangioma and associated regression of hydrops fetalis. AM J OBSTET GYNECOL 1990;163:1180-1) with great interest. The authors reported a case of spontaneous regression of a chorioangioma associated with partial resolution of fetal hydrops with a good neonatal outcome.

The authors did not provide any positive evidence that the regression of the hydrops resulted from the infarcted chorioangioma rather than from the healing of the perforated intestine (meconium peritonitis). Regarding this association, my suggestion is that if fetal echocardiography had been performed it might have strongly supported the viewpoint of this article by showing hemodynamic changes.

Because the progression from a normal status to hydropic change is caused by a chorioangioma that acts as a high-volume arteriovenous shunt to produce a volume overload and cardiac failure in the fetus,[1, 2] any improvement in cardiac decompensation will result in a resolution of the hydrops. We have experienced one case of chorioangioma (7 × 7 × 7.8 cm). A fetal echocardiographic examination was performed once a week beginning with the twenty-fourth gestational week, when the chorioangioma was initially diagnosed. The hydrops developed at the thirty-second gestational week, when the aortic and pulmonary blood flow was noted to have increased to a value two times above normal (720 vs 316 ml/min in the aortic flow, 900 vs 422 ml/min in the pulmonary flow). The hemodynamic changes from an intracardiac Doppler study could have proved whether the placental chorioangioma had a major role in the development of the hydrops fetalis and vice versa, whether it played a role in the regression of the hydrops fetalis.

Chazotte et al. also stated that gradual regression of the placental tumor was seen in the serial ultrasonographic examinations. According to the description in their article, the size of the chorioangioma was measured initially at 5 × 6.5 × 5.5 cm and decreased to 5 × 5 cm. This does not seem to be a clinically significant change.

Finally, I am concerned about the "focal" infarction of chorioangioma. In those cases of placental chorioangioma at our hospital, focal infarction is commonly seen in pathologic specimens. I also wonder if the focal infarction could have had a major effect on the cardiovascular changes in fetal circulation and on the subsequent regression of the hydrops fetalis.

Reply

To the Editors: We appreciate Hsieh and Soong's interest in our case report. We agree that we did not provide positive evidence that the regression of the hydrops fetalis resulted from the infarction of the chorioangioma rather than from healing of the perforated intestine. However, the findings of polyhydramnios and skin edema are unusual in meconium peritonitis in the absence of bowel obstruction[1, 2]; therefore, the hydrops fetalis was more likely to have been the result of the placental tumor.

As illustrated by the case described by Hsieh and Soong, the use of intracardiac Doppler flow studies might have been helpful in determining the cause and the regression of the hydrops in our case. We did not perform such studies with our patient.

With regard to the size of the tumor, the initial dimensions on ultrasonographic examination were 5 × 6.5 × 5.5 cm. Serial sonography revealed that the tumor became smaller, less well visualized, and finally, was recognizable only as a thickened area of placenta without distinct vasculature. In fact, the lesion on the delivered placenta, although measuring 5 × 5 cm, was flattened and infarcted. Thus the volume, nature, and composition changed significantly during the pregnancy. We speculate, as suggested, that the focal infarction of this tumor did play a major role in the resolution of the hydrops fetalis.

More on early detection of preeclampsia

To the Editors: A critical review of available methods for the early detection of preeclampsia was recently published by O'Brien.[1] That Dekker and Sibai (Dekker GA, Sibai BM. Early detection of preeclampsia. AM J OBSTET GYNECOL 1991;165:160-72) view the topic as im-

portant enough to warrant a repetition so soon may well be a testament to the ongoing importance of the topic.

I am unaware of Dekker's personal biases, but it is genuinely reassuring to read that Sibai is steadfast in his vehement opposition to the potential clinical utility of the second-trimester mean arterial pressure (MAP).

Thus it was with a good deal of amusement that I noted that any reference to our work concerning the clinical utility of the second-trimester MAP had been assiduously omitted. In 1988 we presented new data from a prospective study validating second-trimester MAP as an accurate and effective predictor. These results were presented at the national meeting of the American Federation for Clinical Research and the Sixth International Congress of the International Society for the Study of Hypertension in Pregnancy held in Montreal, Canada, in 1988 and were published in 1989[2] and 1990.[4]

No information about the dates of submission and revision for Dekker and Sibai's paper were provided, but Sibai certainly was aware of our work; he attended our presentation at the Montreal meetings in 1988 and roundly criticized our work there. Dekker and Sibai may not agree with our findings. They may be critical of our methods. They may even have missed our paper in the June 1989 issue of *Obstetrics and Gynecology*. Whatever the case, by omitting reference to our work they have failed to provide the readers of the JOURNAL with all the "Current Developments" for the early detection of preeclampsia.

We screened 730 pregnant women at or near 20 weeks of amenorrhea, calculating the screening second-trimester MAP from Korotkoff phases I and V measured in the seated position. Because we had previously documented that adverse outcomes attributable to maternal hypertension were restricted to women with antepartum hypertension,[4] we used antepartum hypertension as the outcome for our study. This represents a more stringent outcome than pregnancy-induced hypertension or preeclampsia because it includes only these cases documented before labor or delivery[4]; those cases account for 45% of all cases of hypertension-complicating pregnancy.[5] The screening second-trimester MAP level of 85 mm Hg proved to be the optimal cutoff for second-trimester MAP as a screening test with sensitivity of 88%, specificity of 84%, positive predictive value of 21.7%, and negative predictive value of 99.3%. Controlling for the value of the screening second-trimester MAP, the only other important predictors of antepartum hypertension were chronic hypertension and diabetes mellitus. With these three variables, the probability that an individual woman will develop antepartum hypertension can be assessed with a high degree of accuracy (84.5%) by 20 weeks of amenorrhea. When women with either chronic hypertension or diabetes mellitus were excluded from the multivariate analysis, second-trimester MAP remained the major predictor of antepartum hypertension ($p < 0.0001$), with the primigravid state and black race being of comparatively minor importance ($p < 0.01$ and $p < 0.05$, respectively).

Assessment of risk for antepartum hypertension with the screening second-trimester MAP is noninvasive, easily transportable, simple, and inexpensive. By combining the screening second-trimester MAP with historic information about chronic hypertension and diabetes mellitus, three distinct levels of risk have been defined:

The low-risk group includes women with screening second-trimester MAP <85 mm Hg with or without diabetes mellitus or chronic hypertension. Antepartum hypertension developed in 0.7% of these women, and antepartum hypertension in combination with maternal and/or infant morbidity occurred in 0.2% of them.

The moderate risk group includes women with second-trimester MAP ≥85 mm Hg in the absence of diabetes mellitus or chronic hypertension. Antepartum hypertension developed in 13.8% of these women, and antepartum hypertension in combination with maternal and/or infant morbidity occurred in 6%.

The high-risk group includes women with second-trimester MAP ≥85 mm Hg in combination with chronic hypertension or diabetes mellitus. Antepartum hypertension developed in 82% of these women, and antepartum hypertension in combination with maternal and/or infant morbidity occurred in 58.8% of them.

This prognostic stratification provides a simple clinical tool for focusing clinical and research resources on subsets of moderate and high-risk women who would be the most likely to benefit.

Reply

To the Editors: It is unfortunate to read that Ales is under the impression that I have certain personal biases either against her work or against her endless obsession with second-trimester MAP. In fact, I found her comments to be neither amusing nor accurate.

The title of our review was "Early detection of preeclampsia," with the emphasis on the word "preeclamp-

sia." Unfortunately, Ales is not an obstetrician, and thus she continues to equate the word "hypertension" with preeclampsia. This was true about 10 years ago; however, recent evidence indicates that there is more to preeclampsia than hypertension.

Ales' cited work involves using one reading at ≤20 weeks' gestation as a screening for second-trimester MAP.[1] In contrast, most data in the literature use the average readings of several values obtained during the second trimester. Her data would have been included if the title of our review was "Early Detection of Hypertensive Disorders of Pregnancy" rather than preeclampsia. Indeed, her prospective study was originally included but had to be deleted because it does not apply to preeclampsia. Fortunately, the original critique of her study was still in the original long manuscript and will thus be set forth here:

A recent prospective study by Ales et al.[1] evaluated the predictive value of one MAP recording at 20 weeks' gestation in 730 women. The authors found a MAP value of ≥85 mm Hg to be clinically significant in predicting antepartum hypertension. Of the 139 women with a MAP ≥85 mm Hg, 21.6% had subsequent antepartum hypertension as compared with a frequency of 0.7% among the women who had a value of <85 mm Hg. Although these results are impressive and the authors used sophisticated multiple logistic regression analysis, the clinical value of this study is doubtful because it only demonstrates that an elevated MAP can be found in the majority of pregnant women in the second trimester along with other well-known risk factors for antepartum hypertension. Among the 139 women with a second-trimester MAP ≥85 mm Hg, the incidence of previous history of hypertension was 39%, a history of chronic hypertension was 12.9%, a history of diabetes mellitus of 2.9%, and a history of perinatal mortality of 15.6%, versus respective rates of 8.5%, 1.2%, 1.0%, and 7.3% in the group with MAP <85 mm Hg. In addition, the study included only six patients with actual preeclampsia (proteinuric hypertension, according to the authors' definition). Thus the conclusions of this study support those of Chesley and Sibai,[2] where it is stated that increased second-trimester MAP predicts transient antepartum hypertension rather than preeclampsia.

Details of electronic fetal monitoring randomized control trials

To the Editors: The randomized control trials on the efficacy of electronic fetal monitoring have widely been interpreted as showing that auscultation and electronic fetal monitoring are "equivalent."[1] Detailed analysis of electronic fetal monitoring patterns from several of these studies, however, tend to betray that interpretation.[2-5]

In both the article by Larson[5] from the premature randomized control trials and the article by Ellison et al. (Ellison PH, Foster M, Sheridan-Pereira M, MacDonald D. Electronic fetal heart monitoring, auscultation, and neonatal outcome. AM J OBSTET GYNECOL 1991;164:1281) with data from the Dublin trial, the authors find an association between adverse outcome and abnormal fetal heart rate (FHR) patterns, but no such correlation with auscultation. This suggests that we cannot rely on even assiduous auscultation for insight into the obstetric (fetal) contribution to neonatal depression and injury.

Ellison et al. emphasize the importance of synthesizing the various components of neonatal evaluation into an estimate of severity and prognosis. Their descriptive classification of FHR patterns characterizes more than 50% as abnormal and more than 20% as ominous; this classification system precludes any understanding of the mechanism, severity, or duration of any fetal insult. The authors imply that the pattern interpretation influenced the operative delivery rate, but they provide few insights. Were ominous patterns present from the outset of labor, were they acted on, and how long was the interval before intervention? The article inappropriately invites the inference that all the adverse outcomes associated with abnormal heart rate patterns developed acutely during labor, not before.

In their introduction the authors suggest that FHR patterns may distinguish the fetus with chronic injuries, but their research attempts no such separation. With the access to FHR tracings, clinical history, and follow-up data, the authors have the unique opportunity to attempt to distinguish those fetuses whose adverse outcome likely preceded labor from those whose handicap likely resulted from asphyxial or mechanical complications of labor and delivery. In others, analysis might reveal no obvious relationship between obstetric factors and outcome. The authors might consider the following scheme: Late, variable, or prolonged decelerations associated with decreased or absent variability from the onset might represent an ongoing asphyxial condition, the interruption of which may not change outcome. Such decelerations developing in a fetus with a previously normal pattern suggest an acute asphyxial event *potentially* amenable to correction or rescue. Persistently absent variability not associated with significant decelerations suggests preexisting abnormality (injury, anomaly) without current hypoxia. Intervention here is unlikely to change the outcome.[6-10]

These subsidiary reports from the randomized control trials clearly imply a benefit to electronic fetal monitoring, at least for the prediction of outcome.[8-10] Only the availability of predictive data on the individual fetus will enable us to understand both the mechanism and timing of insult and the potential for remediation, if any. Each of the randomized control trials raises the

issue of the adequacy of bedside interruption of the tracings. Neither randomized control trial discussed here supports the notion that auscultation and electronic fetal monitoring are equivalent.

Reply

To the Editors: Schifrin indicates that our work showed no correlation between adverse outcome and auscultation. That is not so. In Table VI, the association is shown between FHR abnormalities as assessed by auscultation and the neurologic examinations (an excellent measure of adverse outcome) at 0 to 48 hours and 72 hours to 1 week. For the subsample monitored by auscultation who received neurologic examinations, *FHR abnormality* was the leading and statistically significant indicator of neurologic abnormality at both the 0 to 48 hour ($t = 0.01$) and the 72 hour to 1 week examinations ($t = 0.05$). Many other labor and delivery variables were entered into these data analyses. For the subsample monitored by electronic fetal heart monitoring that received neurologic examinations, late decelerations were the leading indicator of neurologic abnormality at both 0 to 48 hours ($t = 0.00$) and 72 hours to 1 week ($t = 0.00$). Marked bradycardia also was significantly associated with the neurologic evaluation at 72 hours to 1 week ($t = 0.00$).

To analyze the data in the additional ways suggested by Schifrin, the original fetal heart monitoring strips from the Dublin study would need to be reinterpreted in a different manner. As we suggested in the article, trend analysis would probably be more useful for this purpose. Unfortunately, our research team in Denver has not had access to the original tapes, nor have we funding for such a study, however exciting it might be.

Enhanced sensitization after cordocentesis

To the Editors: Recently MacGregor et al. (MacGregor SN, Silver RK, Sholl JS. Enhanced sensitization after cordocentesis in a rhesus-isoimmunized pregnancy. AM J OBSTET GYNECOL 1991;165:382-3) reported a case in which cordocentesis was associated with a marked increase in the maternal indirect Coombs' titer and the subsequent development of immune hydrops. MacGregor et al. suggest that the risk of cordocentesis increasing the maternal sensitization is greater than that of amniocentesis. They made several assumptions or errors in arriving at their conclusion. First, the maternal antibody titer is a reasonable indicator of the fetal risk only during the first sensitized pregnancy.[1] In subsequent pregnancies the variability is too great. Second, at 25 weeks and 3 days they obtained a fetal hematocrit that was already below the 2.5th percentile for gestational age. In other words, the fetus already had anemia. On the basis of our experience, currently consisting of 150 alloimmunized pregnancies, such a fetus has a 90% chance of requiring transfusion therapy if the action line for transfusion is set at 30%.[2,3] The likelihood of the severe anemia developing is so great that these mothers are seen weekly and the fetal blood sampling repeated initially in 7 to 10 days. That this fetus developed a profound anemia is not surprising. An elevated fetal reticulocyte count and total bilirubin level would further increase the index of suspicion. Third, although there is a relationship between the fetal direct Coombs' titer measured initially and hemolytic anemia, it is by no means strong.[2,3] The change in the fetal direct Coombs' titer with advancing gestation has not been studied. Fourth, the authors provide no evidence that cordocentesis is associated with a greater risk of enhanced sensitization than amniocentesis. Abrupt increases in the degree of sensitization after amniocentesis are well documented. We have longitudinally examined approximately 40 pregnancies in which the initial maternal titers were <128 at the time of the first cordocentesis. In only two instances has a ≥ 2-tube dilution increase in the antibody titer been detected during the course of the pregnancy. In both of those instances, the fetal hematologic status was unchanged. We have shown that when a needle guide is used to prevent lateral movement of the needle, the change in maternal serum α-fetoprotein after cordocentesis is similar to that reported for amniocentesis.[4] This differs from the results obtained with a free-hand technique where the increases are larger.[5] As with amniocentesis, it is usually possible to avoid the placenta by performing

the cordocentesis at a midloop. When that is done the risk of worsening sensitization from cordocentesis appears to be no different from that associated with amniocentesis.

In summary, the patient assessed by MacGregor et al. fell into a high-risk category; her worsening fetal hemolytic anemia was predictable from the outset. Although sensitization might have been exacerbated by placental puncture, it is the way the procedure was performed in this instance rather than the procedure itself that is of concern.

Reply

To the Editors: We thank Weiner for his interest in our article. We agree that a low maternal antibody titer cannot be used to ensure the absence of fetal risk after a previously affected pregnancy, and we therefore offered the patient either amniocentesis or cordocentesis. However, the report that was the basis for this management does not imply that a higher titer poses no greater risk for the fetus.[1] We expect that a maternal titer of 1:4096 (after initial cordocentesis) is more likely to be associated with severe fetal anemia than a titer of 1:8 (before cordocentesis). At initial sampling the fetal reticulocyte count was 15.4%, direct Coombs titer 1+, and hematocrit 30.9%. Our experience also suggests that such a fetus is likely to have the hematocrit decrease to <30% and require transfusion. However, in such cases monitored with weekly ultrasonographic examinations and repeat cordocentesis, we have not seen an additional fetus develop hydrops and decrease the hematocrit to 12% in a 3-week period. A decline in the hematocrit to <30% is much different from 12%. Data are not available from the report by Weiner et al. addressing the rapidity of hematocrit decline in patients such as we described, although we suspect that our case is uncommon.[2] No data are available comparing the risk of enhanced sensitization after amniocentesis versus cordocentesis. Although Weiner et al. demonstrated little increase in maternal serum α-fetoprotein levels after cordocentesis, avoiding transplacental needle entry,[3] we are unaware of the correlation between elevation of maternal serum α-fetoprotein and the risk of enhanced sensitization in alloimmunized pregnancy. A secondary immune response may occur after introduction of <1 ml of antigen-positive red blood cells. Maternal serum α-fetoprotein elevation would likely occur only with much greater fetal blood contamination. This study did not compare needle-guided cordocentesis with either amniocentesis or free-hand cordocentesis; therefore, it is not possible to assess the relative risks of fetal blood entering the maternal circulation. Finally, we agree that placental puncture during cordocentesis may be associated with risks and avoided if feasible; however, needle placement in a free loop of umbilical cord may also be associated with risks, including technical difficulty of cord movement and more frequent dislodgment, particularly if transfusion is necessary.

Although cordocentesis has improved both evaluation and therapy of fetuses with red blood cell alloimmunization, potential risks such as enhanced sensitization must be considered. As other reports have suggested, midtrimester amniocentesis should continue to be an option in the evaluation of these fetuses.[4]

Increasing use of gynecologic ultrasonography

To the Editors: I read with great interest the ultrasonography panel developed by the American Gynecological and Obstetrical Society, especially the article by Willson (Willson JR. Ultrasonography in the diagnosis of gynecologic disorders. AM J OBSTET GYNECOL 1991;164:1064-71.) in which my work was discussed. Willson's material was well thought out and timely, and it gave me some new perspectives. Still I feel obligated to comment.

First, one constant theme has to do with the "cost-effectiveness" of increasing use of gynecologic ultra-

sonography with the vaginal probe. All of the analyses and comments seem to assume that every time the probe is used the patient incurs a separate, additional charge of $150 to $200. This need not be true. The ultrasonographically enhanced bimanual examination adds very little time, and as vaginal probe equipment becomes smaller and dedicated and is used more routinely the *true* costs will be a mere fraction of what people currently charge.[1] This will be especially true in terms of our concerns about earlier diagnosis of ovarian cancer. We already screen for this disease: it is called the annual gynecologic visit. Admittedly this has an inadequate pick-up rate in the early stages of the disease. However, as vaginal probe–enhanced bimanual examination becomes more widespread, these will be an improvement in detection. Once again, the dollar numbers quoted are not true indicators of cost, either current or future.

Second, Willson correctly points out that most reports on the use of ultrasonography in gynecology come from those like myself who have some background in diagnostic imaging. Currently many practitioners are learning imaging at postgraduate courses and then going out and creating their own learning curves. Thus Willson believes the diagnoses made by this group are less accurate than those made by the imaging professionals. Initially this may be true. However, the beauty of the vaginal probe is that it *is* a diagnostic modality. A new entrant into the field can and should have a variable learning curve. Although physicians acquire experience and confidence with their own diagnoses generated with vaginal probe ultrasonography, they can and should continue to triage such patients as they did before they used the probe. This is not an all-or-none phenomenon. We continue to improve our wealth of knowledge, experience, and skill over our entire professional lives. Furthermore, the real key to upgrading physicians skills in this country lies in residency training. Every resident who finishes a program without the necessary skills becomes part of the problem, not the solution. It will take an entire generation of obstetricians and gynecologists to fully implement such new technology, but certainly in our institution it is well on its way.

Finally, Willson makes the point that identification of small myomas, ovarian enlargements, and physiologic cysts will lead to increased patient concern and unnecessary operations. I share this concern greatly. The biggest potential problem with this new technology is overinterpretation of such findings and merely applying old clinical approaches to information obtained with such increasingly refined technology. Along with the introduction of such technology, education of both physicians and patients is mandatory. I realized this very early on and have committed myself to it. For instance, use of words like "cyst" need to be rethought. It is petrifying to the uneducated patient. It merely means "filled with fluid," is easily seen on ultrasonography and says nothing about cause or significance. I appreciate Willson's help in this arena, but the answer is not to abandon the technology, but rather to do further appropriate studies to responsibly incorporate the technology into routine patient care.

Steven R. Goldstein, MD
New York University Medical Center, 530 First Ave., Suite 5E, New York, NY 10016

REFERENCE

Reply

To the Editors: I appreciate Goldstein's comments. He, of course, is one of the leaders in the use of diagnostic ultrasonography by obstetrician-gynecologists.

Goldstein is less concerned than I and others over the cost of ultrasonography and other examinations when they add little to diagnostic accuracy. Ultrasonographic equipment must be paid for; as technology improves new machines must be purchased and paid for, not by the physicians who use them, but by their patients. I doubt that the additional charge for office visits that includes ultrasonographic examinations will be eliminated after the equipment is amortized. Hillman et al. calculated that physicians who own ultrasonographic equipment use diagnostic imaging 4.0 to 4.5 times more often than those who refer patients to radiologists. In addition, the charge for obstetric ultrasonographic examinations by self-referring physicians averages $178 per examination as compared with $25 by radiologists. Hillman et al. state, "The differences between self-referring physicians and radiologist-referring physicians in the use of imaging are so great that some concern over the role of financial incentives must be invoked."

I agree with Goldstein and stated in my article that the accuracy of ultrasonographic diagnosis will improve with advancing technology and increased experience in interpreting the images.

Goldstein seems to agree with my statement that "When expertise in this important adjunctive examination is expanded and when it is taught in departments of obstetrics-gynecology by obstetrician-gynecologists, most residents will become as competent in gynecologic ultrasonographic diagnosis as they now are in obstetrics."

The last sentence of Goldstein's letter seems to imply that I suggested that ultrasonography be abandoned. This does not in any way reflect what I believe or said, which is simply that at the moment it appears that ultrasonography is being overused and that its best use is as a secondary, not a primary, diagnostic tool.

At last: An objective observation

To the Editors: Congratulations to Dr. Ward on his article (Ward CJ. Analysis of 500 obstetric and gynecologic malpractice claims: causes and prevention. AM J OBSTET GYNECOL 1991;165:298-306). Although I am not sure exactly how Dr. Ward identified the cases he defined as "defensible" or "undefensible," the most important aspect of the article to me was that physicians are now able to admit that—no matter what the percentages are—negligence, malpractice, deviation from the standard of care, and bad doctors, call it what you will, do occur.

Dr. Ward has expended great energy looking at cases and trying to make sense of them; for that I congratulate him. It is refreshing to read a more objective response to the malpractice issues than the usual party-line drivel that is given to physician readers.

On the other hand, Dr. Freedman's inflammatory comment decrying the fact that the crisis becomes "so terribly lucrative to one other profession," is the response that ignores the medical profession's problem and projects derogation toward the legal profession.

Finally, Dr. Blanchard's insinuation (promulgated by others) regarding any and all medical experts in malpractice trials (somewhat derogatorily referred to as "these people"), that good, upright, proper, outstanding physicians would never dare speak out critically of fellow physicians, is also typical of the profession's attitude and should be strongly denounced. Her anecdotal and apocryphal comments that, ". . . we have medical experts stating that the patient had an enema and that this caused the baby to be brain damaged . . ." is pure hockey puck.

Please keep up the good work in providing information about the medical negligence area to your readers.

Animals and ethics: How society's attitudes have changed

To the Editors: There has been a drastic change in the social and philosophic Zeitgeist and with it our attitudes toward the treatment of animals. Criticism of the use of animals in biomedical research no longer can be brushed aside merely as antiscientific or antiintellectual. J.M. Maharry correctly observed, in his presidential address, "The issue of animal rights and human rights" (AM J OBSTET GYNECOL 1991;164(6):1543-8), that researchers and members of the medical profession can no longer afford merely talking to each other about the fact that "60 million Americans do not approve the use of living animals in research." What's urgently needed is careful listening to what other segments of society think about this highly controversial issue, rather than embarking on a high-tech advertising campaign in support of the status quo, as Maharry proposes.

That animals, in fact, have interests, because they, like humans, can suffer, and thus have an interest in avoiding suffering, is a subject being argued by students of philosophy throughout the United States and elsewhere. An increasing number of articulate philosophers have demonstrated in their writing, "a coming maturity in animal ethics that can't be dismissed as either sentimentalist or scientifically uninformed," as stated by Burghardt.[1] We are less and less on firm philosophic ground if we continue to adhere to the anthropocentric view that all nonhuman life exists only for man's use and benefit. The paucity of contemporary philosophy in firm support of this anthropocentric belief is striking. Ethology, neurobiology, and other disciplines have taught us that animals share with us many cognitive and perceptual attributes that make highly invasive procedures no longer merely an issue of freedom to conduct research. Even the issue of potential human benefit would appear in a different light under these circumstances.

Maharry reiterated the self-serving claims by animal researchers that without animals there would not be "a single modern and substantial item of medical knowledge." Consider the cure of childhood leukemia and lithium for the treatment of manic-depressive illness, two examples frequently attributed to animal research.[2] Yet medical historian Brandon Reines has discovered that patient-centered clinical investigation was behind these success stories.[3]

Finally, Maharry is simply misinformed for failing to see that the animal rights movement encompasses concern for the environment and a host of other human rights issues. A recent survey conducted at Oregon

State University under a grant by the Putting People First Foundation[4] confirmed just that.

Ulrich Fritzsche, MD
Total Healthcare for Women, 1530 North 115th St., Suite 308, Seattle, WA 98133

Reply

To the Editors: As is so typical of zealots, they defend their position by attacking the motives of their perceived enemies. I refer to Fritzsche's statement, "self-serving claims by animal researchers." To validate this statement, he implies that childhood leukemia and manic-depressive illness were cured without the benefit of animal research. His inference that no animal studies were involved in effecting the cure of these two diseases is either hopelessly naive or it is deliberate misinformation.

Consider the drugs used in the treatment of the two diseases: lithium carbonate in the treatment of manic-depressive illness and various combinations of doxorubicin, vincristine, prednisone, asparaginase, 6-mercaptopurine, and methotrexate in the treatment of childhood leukemia. It is ludicrous to suggest the Food and Drug Administration would release these drugs for clinical study had there not been prior, and extensive, testing on laboratory animals.

Fritzsche is in error when he writes: "Maharry is simply misinformed for failing to see that the animal rights movement encompasses concern for the environment and a host of other human rights issues."

In my address it was emphasized that for more than 150 years organizations with genuine concern for the welfare of animals have served as the conscience of society. During the past 10 years, however, the animal rights movement has evolved into a vast industry, characterized by an increasing militancy. I documented criminal acts such as: attempted murder, arson, burglary, grand theft, breaking and entering, and terrorist bombings, all committed under the banner of the animal rights movement. These wanton criminal acts are not compatible with environmental concern and a host of human rights issues.

Corrections

In the article by Helmrich, Stubbs, and Stoerker entitled "Fetal maternal laryngeal papillomatosis in pregnancy: A case report" (AM J OBSTET GYNECOL 1992;166:524-5), on page 524, the title should have been "Fatal maternal laryngeal papillomatosis in pregnancy: A case report."

In the article by Vintzileos et al. entitled "Relationship between biophysical activities and umbilical cord blood gas values" (AM J OBSTET GYNECOL 1991;165:707-13), page 711, Table VI is entitled "Umbilical artery blood gas values associated with compromised biophysical activities"; it should have been "Umbilical vein blood gas values associated with compromised biophysical activities." The correction that appeared in the February 1992 JOURNAL (1992;166:772) erroneously listed Table V as the incorrectly titled table.

In the article by Feinberg et al. entitled "Increased progesterone concentrations are necessary to suppress interleukin-2–activated human mononuclear cell cytotoxicity (AM J OBSTET GYNECOL 1991;165:1872-6), on page 1873, between the paragraphs entitled "Effector cells" and "Cytotoxicity assay" the following paragraph should have appeared:

Target cells. Chang liver cells were grown to confluence in supplemented minimum essential media in 25 cm^2 culture flasks. The cells were removed with trypsin (0.25%) and ethylenediaminetetraacetic acid (0.02%) in saline solution, washed in 10 ml of supplemented minimum essential media, and centrifuged at 200*g* for 10 minutes. The pellet was resuspended in 150 μl supplemented minimum essential media and radiolabeled with 50 μCi sodium chromate (Dupont/New England Nuclear, Cambridge, Mass.). After 90 minutes of incubation at 37° C in 95% air and 5% carbon dioxide, the cells were layered over 3 ml of inactivated fetal calf serum, centrifuged for 10 minutes at 200*g*, washed three times in supplemented minimum essential media, and resuspended to a final concentration of 1×10^5 cells per milliliter in supplemented minimum essential media.

ITEMS

Announcements of major meetings and other significant activities must be received at least 8 weeks before the desired month of publication. All announcements carry a charge of $60.00 U.S. per insertion and the fee must accompany the request to publish. BRONSON

Obstetrician/Gynecologist Opportunity Available
Kalamazoo, Michigan

A practice opportunity is available for BE/BC Ob/Gyns to join a well-established, busy hospital-based group practice. Excellent salary and malpractice insurance are among the many benefits of this opportunity. Relocation and interviewing expenses will also be provided.

Administrative prerequisites have been established for a Nurse Midwifery Service for this practice and recruitment is also underway for experienced CNMs.

Bronson Hospital, the 442-bed tertiary care facility for southwestern Michigan, has a 500-member medical staff which includes 31 Ob/Gyns, 3 perinatologists and 6 neonatologists. An average of 3,400 deliveries are performed annually at Bronson.

Kalamazoo, located midway between Chicago and Detroit, offers diverse cultural opportunities. Lake Michigan's sandy beaches and dunes are only minutes away and numerous lakes, hills and forests provide boundless recreational activities. Excellent schools, several colleges and a major university further contribute to a high quality life-style. Real estate is affordable and one can be in the beautiful countryside within 10 minutes.

For more information about this practice opportunity, please call or send CV to:

Debra Hartman, Bronson Administrative Services
252 E. Lovell St., Kalamazoo, Michigan 49007
(800) 594-9022 or (616) 341-6331

SHOCK YOUR FAMILY & FRIENDS! Tell them you're looking at practicing in eastern North Dakota or western Minnesota! Our countrypolitan lifestyle includes commutes of up to 9 minutes, 6-car traffic jams, unlocked doors, exceptional schools, bagging the limit in fish and game or just dangling your feet off the dock. The Dakota Clinic is a 154-person multispecialty group looking for OB/GYN physicians. Specific sites include Fargo and Jamestown, North Dakota, as well as Detroit Lakes or Park Rapids, Minnesota. Excellent salary and benefits with stockholder opportunity after two years. There are minimal buy-in requirements. To receive our video and community practice information kit, call Dick Reis at 1-800-342-4926, or write: **Dick Reis, Manager, Recruiting, Dakota Clinic, Ltd., 1702 South University Drive, Fargo, ND 58103.**

FACULTY POSITIONS
GENERALIST OBSTETRICIAN/ GYNECOLOGIST
MATERNAL/FETAL MEDICINE SUBSPECIALIST
GYNECOLOGIC ONCOLOGIST
REPRODUCTIVE ENDOCRINOLOGIST

The James H. Quillen College of Medicine of East Tennessee State University offers an excellent opportunity to physicians of these specialties who are Board Certified or Board Eligible. This opportunity offers both tangible and intangible benefits sometimes not found in larger cities. Our emphasis is on excellence in service to patients, education, and research. These Faculty positions, both Tenure track and Grant-supported, are at the Assistant/Associate Professor level and offer very competitive salaries and excellent fringe benefits. The Gynecologic Oncologist position is funded by an outside source. The Tri-Cities area boasts of good schools and suburban living in beautiful Northeast Tennessee with easy access to various cultural activities. Our outdoor sports include all water sports, snow skiing, the Appalachian Trail, and numerous scenic attractions. Our medical referral base consists of 1.3 million people within a 50 miles radius. Perinatologist Needed in Coastal New Jersey

2 member group is seeking a third perinatologist (BE/BC). We are active practitioners of perinatology and we also serve as integral members of the teaching team for a residency in Obstetrics and Gynecology.

We engage in both in-patient and out-patient activities, and all skills related to maternal fetal medicine may be used within our practice. Strong ultrasound skills are required, and the current practice consists of antenatal diagnosis, genetic counseling, amniocentesis, CVS and PUBS. We will insist on comfort and competence in basic obstetrical practice.

We are located about 1.5 hours from both New York City and Philadelphia, and the area provides a suburban life style.

Contact: Glenn Herman, M.D.
David Wallace, M.D.
Telephone: (908) 870-3600
Fax: (908) 870-0119

MATERNAL/FETAL SUBSPECIALISTS
EASTERN PENNSYLVANIA

Lehigh Valley Hospital, an 830-bed tertiary care teaching hospital, is seeking additional faculty including two full-time maternal/fetal medicine subspecialists: a division chief and an associate. The physicians' roles will include consultative patient care, program development, student and resident education and research if desired. The opportunity exists to customize the role to your particular career goals. Candidates should be board certified or active candidates for certification in maternal/fetal medicine.

Lehigh Valley Hospital is a regional Perinatal Center with over 3,300 births annually, of which 40 percent are high-risk. The department is supported by a 20-bed Level III NICU and four full-time neonatologists. The hospital serves as a clinical campus of Hahnemann University and maintains a free-standing, fully-accredited OB/GYN residency program.

Allentown, Pennsylvania is a cosmopolitan city, 60 miles north of Philadelphia and 80 miles west of New York City. The area has excellent school systems, nine colleges and universities and diverse cultural offerings. An excellent compensation package has been designed to recruit qualified candidates. Please send CV to **Carol Voorhees, Vice President, Lehigh Valley Hospital, 1243 S. Cedar Crest Boulevard, Suite A, Allentown, PA 18103, or call (215) 821-3090.** EOE.

NORTHERN CALIFORNIA– BAY AREA
PERINATOLOGIST

Outstanding opportunity for BE/BC perinatologist to join solo private practice. The Good Samaritan Hospital is a private, level III center with over 4,000 deliveries annually. NICU is staffed by five neonatologists. Excellent institutional support with full range of prenatal diagnostic services and state-of-the-art Antepartum Testing unit. Experience desired in CVS, prenatal diagnostic ultrasound, PUBS and complicated pregnancies.

San Jose is located 40 miles south of San Francisco. Exceptional lifestyle and financial package.

Call (408) 559-2258 or send CV to:

Kevin J. Gomez, M.D.
2425 Samaritan Drive
San Jose, CA 95124

Women's Health Care of Hinsdale, a four-person general obstetrics and gynecology group, is looking for an energetic, BC/BE physician to join them full-time in private practice. Our physicians are exclusively on staff at Hinsdale Hospital, a 459-bed facility with 10 LDR's, a Level II+ nursery, 24-hour neonatology services, and 24-hour in-house anesthesia services dedicated to Labor and Delivery.

Hinsdale, Illinois is located 17 miles southwest of downtown Chicago in a beautiful, upscale western suburb. Our location offers us the opportunity to take advantage of the best that Hinsdale has to offer – exceptional schools, housing, shopping, dining – in addition to being able to enjoy things that are uniquely Chicago – The Art Institute, the Chicago Symphony Orchestra, world-class professional sporting events...all just minutes away.

Our salary and benefits package is highly competitive. Since we would like to discuss our opportunity with you in more detail, please reply with your CV to Margaret Pfister, M.D., Women's Health Care of Hinsdale, 333 Chestnut, Suite 201, Hinsdale, IL 60521 or call 708/920-2229.

PERINATOLOGIST OGDEN, UTAH

An outstanding opportunity exists for a perinatologist to set up a consultative practice in Ogden, Utah. The physician will be an employee of McKay-Dee Hospital, a 415-bed community facility. Office space, personnel and equipment will be provided by the hospital. The successful candidate will be an integral part of Intermountain Health Care's Perinatal Group.

Ogden, Utah is a beautiful community of 69,000, with a service population of 260,000. There is an abundance of outdoor recreation available, including skiing, snowmobiling, hunting, fishing, boating, swimming and camping. A variety of cultural events entertain and amuse Ogden residents, such as the symphony, the ballet, museums, art galleries and festivals. Ogden is a short 40 minutes from Salt Lake City where more professional sports and cultural events may be found.

Faculty Opportunities
Obstetrics, Gynecology and Reproductive Science

Excellent opportunities exist for Board-certified or eligible physicians to join our internationally recognized faculty consisting of twenty full-time clinicians, five research investigators and sixty-five voluntary attendings, as well as twenty-eight residents and fellows in each of three subspecialty divisions.

OB/GYN GENERALISTS

These individuals will have primary teaching and clinical responsibilities on the obstetrical and gynecologic services. The selected individuals will be appointed to the departmental faculty and have the opportunity to pursue private practice opportunities.

PERINATOLOGISTS

The Division of Maternal Fetal Medicine is a major referral center for high risk pregnancies and fetuses at risk or suspected to have anomalies, and offers a broad range of services including vaginal and abdominal ultrasound, fetal blood samples, fetal echocardiography and a large spectrum of intrauterine procedures. Faculty members have service and consultative responsibilities along with those of teaching medical students, residents and maternal fetal medicine fellows. We seek individuals who are interested in careers in academic medicine, research, teaching and patient care.

GYNECOLOGIC ONCOLOGIST

This faculty position involves all clinical and teaching responsibilities, and participation in research opportunities. Members of the Division of Gynecologic Oncology hold senior positions in national and international organizations, and continue to develop cancer therapies which have become the standard for treatment worldwide.

We offer highly competitive salaries and benefit package including professional liability coverage, medical and dental coverage, pension and continuing education.

For consideration, please direct your letter, curriculum vitae and the names of three references to: Richard L. Berkowitz, Professor and Chairman, Department of Obstetrics, Gynecology and Reproductive Science, Box 1170, The Mount Sinai Medical Center of New York, One Gustave L. Levy Place, New York, NY 10029-6574. An Equal Opportunity Employer.

OB/GYN Generalists & Specialists

High-Risk Obstetrics & Maternal Child Health

The Saudi Arabian Oil Company's (SAUDI ARAMCO) Medical Services Organization in Saudi Arabia has immediate openings for **Obstetricians/Gynecologists** and a **Perinatologist.**

American Board Certification and 2 years' experience after residency required.

The Dhahran Health Center (DHC) in Saudi Arabia provides comprehensive medical care to our employees and their dependents, a patient population of nearly 230,000. The DHC, recently expanded to 483 beds, has all major specialty services as well as most subspecialties and functions as a referral center. Additionally, there are five district outpatient clinics, each with emergency facilities, including one clinic with a new 80 bed hospital. Our Blood Bank is accredited by the American Association of Blood Banks. Consulting liaisons exist with the WHO in Geneva and the Centers for Disease Control in Atlanta.

As a Saudi Aramco employee, you will receive a competitive base compensation package as well as an expatriate premium. Additional benefits include noncontributory group life insurance, company-matched savings, free medical care at Saudi Aramco's hospital and clinics, housing inside a company community, and extensive recreation facilities and activities. Your eligible children will be enrolled in company schools, comparable to U.S. private schools. Annually, there are up to 13 company holidays plus you will be eligible for 36 calendar days vacation, with round-trip airfares to the U.S. or Canada for you and your family.

For consideration, **CALL OUR**
24 HOUR, 7 DAYS PER WEEK
TOLL-FREE NUMBER LISTED BELOW:

1-800-221-3333, EXT. R1

SAUDI ARAMCO

Make the winning move.

THE DEPARTMENT OF OBSTETRICS AND GYNECOLOGY UNIVERSITY OF WISCONSIN MEDICAL SCHOOL

is seeking applicants for two (2) full-time faculty positions for a new women's health center and academic program at its Milwaukee Clinical Campus.

Sinai Samaritan Medical Center has recently consolidated its obstetrical and gynecological services in a redesigned facility in downtown Milwaukee. The department supports a residency program, the largest perinatal service in Wisconsin (5500 deliveries), consultative ultrasound, genetic and infectious disease programs, and reproductive/endocrine services (including an IVF program). The department is affiliated with Planned Parenthood of Wisconsin and St. Luke's Medical Center in Milwaukee.

Qualifications include a board candidacy or certification in obstetrics and gynecology and a commitment to teaching residents, medical students, and clinical research. Qualifications for the two positions for GENERAL OB/GYN can take into consideration special individual interests. Special expertise of interest for the department are:

—STATEWIDE FAMILY PLANNING
(Part-time medical director, Planned Parenthood)
—OPERATIVE LAPAROSCOPY, HYSTEROSCOPY
—UROGYNECOLOGY
—OB/GYN ULTRASOUND

Private practice opportunities are also available in an associated offsite multispecialty clinic and all faculty members participate in a group practice at the institution. Contact:

Chester B. Martin, M.D.
Chairman
Department of Obstetrics and Gynecology
University of Wisconsin Medical Schl.
600 Highland Avenue, H4/654 CSC

The University of Wisconsin Medical School is an equal opportunity employer

OB/GYN Subspecialists

Gynecologic Oncology
Perinatology
Reproductive Endocrinology
Urogynecology

The University of South Dakota School of Medicine's Department of Obstetrics and Gynecology is building a full time academic team. We are located in Sioux Falls, South Dakota, a regional medical community of 120,000 serving South Dakota and three neighboring states.

Challenging positions are available for qualified candidates interested in pioneering medical education, research development and clinical practice.

A new comprehensive University-Health Science Center is being constructed which will house our program. Outreach and Indian Health opportunities are also available.

Financial package and incentives are competitive and commensurate with experience, credentials and rank.

Please send Curriculum Vitae to: R. H. Wiebe, M.D. Professor and Chairman, Department of Obstetrics and Gynecology, c/o Physician Placement Program, 1100 South Euclid Avenue, Sioux Falls, South Dakota 57117-5039 or call 800-468-3333 for more information.

CHAIRMAN DEPARTMENT OF OBSTETRICS/GYNECOLOGY

Saint Joseph Hospital and Health Care Center, a 497 bed hospital, affiliated with Northwestern Medical School, seeks a full time Chairman for its Department of OB/Gyne. The Senior attending, Board Certified candidate will direct the department and residency program in Obstetrics and Gynecology, expand its services and assure quality patient care. Demonstrated accomplishments in medical education and administration are essential.

Submit a C.V. to:

P.C. Williams, M.D., Chairman
Search Committee
Saint Joseph Hospital and Health Care Center

Chicago, IL. 60657

DIRECTOR MATERNAL FETAL MEDICINE

Department of Obstetrics and Gynecology
University of Medicine and Dentistry of New Jersey
Robert Wood Johnson Medical School

The Robert Wood Johnson Medical School invites applications for **Director of Maternal-Fetal Medicine.** The position of Director requires an individual with an established and broad understanding of medical education, research, patient care as well as effective administrative skills. Applicants should possess qualifications commensurate with those of an Associate Professor/Professor of Obstetrics and Gynecology as defined by the Robert Wood Johnson Medical School.

The Division is located at St. Peter's Medical Center, the largest obstetrical and neonatal program in the State. Maternal-Fetal Medicine consists of five perinatologists, two MFM Fellows, four sonographers, a geneticist, two research nurses and one epidemiologist/biostatistician. The Robert Wood Johnson Program supports 7,000 deliveries per year.

Interested individuals should forward their curriculum vitae to:

Robert A. Knuppel, M.D., M.P.H.
Professor and Chairman
UMDNJ-Robert Wood Johnson Medical School
One Robert Wood Johnson Place-CN 19
New Brunswick, New Jersey 08903-0019

The UMDNJ is an Affirmative Action/Equal Opportunity Employer M/F/H/V and a member of the University Health System of New Jersey

One full-time position is available in the Department of Obstetrics and Gynecology, University of California, Davis, Medical Center, Sacramento, as Director of the Division of Maternal/Fetal Medicine with concurrent appointments to the faculty of the University of California, Davis, School of Medicine. Applicants for this perinatologist position should be Board eligible or certified in Obstetrics and Gynecology and must have successfully completed subspecialty training in Maternal/Fetal Medicine with subsequent Specialty Board eligibility and/or certification in Maternal Fetal Medicine. Applicants must possess or be eligible for medical licensure in the State of California. Applicants must demonstrate experience and competence in teaching effectiveness and research related activities or potential for such activities. Applicants must demonstrate experience in prenatal diagnosis, ultrasound and genetics.

Responsibilities of this position include direction and responsibility for research activities in the division, both inpatient and outpatient case management, surgery and procedures specific to high risk obstetrics, participation in teaching activities with residents, interns and medical students, development and/or participation in research activities and involvement in University and Hospital committees. Serves as Administrative Director of the Division.

Send curriculum vitae and five references to:

R. Jeffrey Chang, M.D.
Chairman, Department of Obstetrics and Gynecology
University of California, Davis, Medical Center
1621 Alhambra Boulevard, Suite 2500
Sacramento, California 95816

The final date for receipt of applications is May 31, 1992.

The University of California, Davis is an equal opportunity, affirmative action employer.

Maternal-Fetal Medicine Faculty
Department of Obstetrics and Gynecology
University of Medicine and Dentistry of New Jersey
Robert Wood Johnson Medical School
Three Positions Available

The Department of Obstetrics and Gynecology of the UMDNJ-Robert Wood Johnson Medical School invites applications for three full-time faculty positions as Specialists in Maternal-Fetal Medicine. Candidates should be board certified or eligible in Maternal Fetal Medicine. The positions involve academic practice, graduate and undergraduate medical education, and clinical and/or laboratory research.

The Division is located at St. Peter's Medical Center which has the largest obstetrical and neonatal program in the State. MFM Fellowship approved. Four MFM specialists, four sonographers, a geneticist, two research nurses and one epidemiologist/biostatistician are currently in the Division. Academic Rank and competitive salary commensurate with level of experience and qualification.

ASSISTANT/ASSOCIATE PROFESSOR MATERNAL-FETAL MEDICINE

The University of North Carolina at Chapel Hill Department of Obstetrics and Gynecology in conjunction with the Wake Medical Center, Raleigh, North Carolina, and the Wake Area Health Education Center has an opening for a board certified or active candidate perinatologist with a special interest in high risk pregnancies and ultrasound. The position is in the Wake AHEC OB/GYN Department which has three full-time obstetricians and gynecologists, plus the program director who is board certified in Maternal-Fetal Medicine. Wake Medical Center is located in Raleigh, approximately 40 minutes from Chapel Hill, and is a 560-bed comprehensive tertiary care center with over 4000 deliveries per year and a neonatal intensive care unit staffed by four neonatologists. Excellent opportunity for research and teaching residents and medical students rotating through Wake Medical Center at all times. Collaboration with the Maternal-Fetal Medicine Division at Chapel Hill is encouraged and anticipated. Competitive salary and excellent fringe benefits.

Write or contact:

The Osler Institute
Obstetrics and Gynecology Review Course

June 8-13, 1992 – Pittsburgh

October 5-10 – Nashville †Nov. 30-Dec. 5 – Chicago

Your course for exams with practice tests and case-list reviews

OBJECTIVES
- Increase basic knowledge and clinical skills in ob-gyn
- Assist residents and fellows to organize their study
- Prepare candidates to take their examinations
- Provide practicing gynecologists with an update

METHODS
- HOME STUDY MATERIALS with questions and answers
- SEMINAR with projection slides and lecture-note syllabus
- LABORATORY with microscope and glass slides
- PRACTICE EXAMS for your orals

†Plus extra mock oral days December 6-8.

*"The faculty was outstanding. The most pleasant thing was learning a tremendous amount, not only from world-famous authorities, but from people who are relatively unknown as well."**

Clinical Science
- Surgical Anatomy

*"The course was extremely helpful to me."**

COURSES: Fall courses are more clinically oriented. The course includes lectures with syllabus as well as an opportunity for you to buy an unlimited number of 25-minute, one-on-one sessions with faculty to review your case lists or perform mock oral exams. The optional extra days, Dec. 6-8, include a pathology laboratory session, one mock oral exam and observation of seven or more hours of other exams. Past participants recommend repeating the course for half price immediately before exams.

*"Accommodations were comfortable...."**

LOCATION: The Pittsburgh course will be held at the Royce Airport Hotel at the Pittsburgh Airport.

*"...and those little extras...."**

DISCOUNT AIR FARES: Please call toll-free (800) 627-8468 for group discounts.

*"...the most education for the money."**

FEES FOR CATEGORY 1 HOURS:
- Practicing Gynecologist: $780
- Resident or Fellow: $520
- Repeating course within 2 years: $390
- Optional extra days, December 6-8 (per day fee): $180
- **Add 10% within 10 days of the course.**
- Attendees not in course hotel add $20/day.
- A deposit of $50 will reserve your position.

*"...home study material was extremely helpful."**

ACCREDITATION: Jointly sponsored by Penn State's College of Medicine at The Milton S. Hershey Medical Center. Penn State is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to sponsor continuing medical education for physicians.

CREDIT: Penn State designates this continuing medical education activity for **60 credit hours** in **Category 1** of the Physician's Recognition Award of the American Medical Association.

*"...remarkably complete and pleasant."**

ORTHO-NOVUM 777 Tablets

TRADEMARK

norethindrone/ethinyl estradiol

Each white tablet contains 0.5 mg norethindrone and 0.035 mg ethinyl estradiol. Each light peach tablet contains 0.75 mg norethindrone and 0.035 mg ethinyl estradiol. Each peach tablet contains 1 mg norethindrone and 0.035 mg ethinyl estradiol. Each green tablet in 28-day regimen contains inert ingredients.

IMPORTANT NOTE—This information is a BRIEF SUMMARY of the complete prescribing information provided with the product and therefore should not be used as the basis for prescribing the product. This summary was prepared by deleting from the complete prescribing information certain text, tables and references. The physician should be thoroughly familiar with the complete prescribing information before prescribing the product.

INDICATIONS AND USAGE: PREVENTION OF PREGNANCY.

CONTRAINDICATIONS: Oral contraceptives should not be used in women who currently have the following conditions: 1. Thrombophlebitis or thromboembolic disorders. 2. A past history of deep vein thrombophlebitis or thromboembolic disorders. 3. Cerebral vascular or coronary artery disease. 4. Known or suspected carcinoma of the breast. 5. Carcinoma of the endometrium or other known or suspected estrogen-dependent neoplasia. 6. Undiagnosed abnormal genital bleeding. 7. Cholestatic jaundice of pregnancy or jaundice with prior pill use. 8. Hepatic adenomas or carcinomas. 9. Known or suspected pregnancy.

WARNINGS

Cigarette smoking increases the risk of serious cardiovascular side effects from oral contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia, and gallbladder disease, although the risk of serious morbidity or mortality is very small in healthy women without underlying risk factors. The risk of morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemias, obesity and diabetes. Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks. The information contained in this brief summary is principally based on studies carried out in patients who used oral contraceptives with higher formulations of estrogens and progestogens than those in common use today. The effect of long term use of the oral contraceptives with lower formulations of both estrogens and progestogens remains to be determined. Throughout this brief summary epidemiological studies reported are of two types: retrospective or case control studies and prospective or cohort studies. Case control studies provide a measure of the relative risk of a disease, namely a *ratio* of the incidence of a disease among oral contraceptive users to that among nonusers. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide a measure of attributable risk, which is the *difference* in the incidence of disease between oral contraceptive users and nonusers. The attributable risk does provide information about the actual occurrence of a disease in the population. For further information, the reader is referred to a text on epidemiological methods. 1. THROMBOEMBOLIC DISORDERS AND OTHER VASCULAR PROBLEMS. a. Myocardial Infarction. An increased risk of myocardial infarction has been associated with oral contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary artery disease such as hypertension, hypercholesterolemia, morbid obesity, and diabetes. The relative risk of heart attack for current oral contraceptive users has been estimated to be two to six. The risk is very low under the age of 30. Smoking in combination with oral contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women in their mid-thirties or older with smoking accounting for the majority of excess cases. Mortality rates associated with circulatory disease have been shown to increase substantially in smokers, especially in those 35 years of age and older among women who use oral contraceptives. Oral contraceptives may compound the effects of well-known risk factors, such as hypertension, diabetes, hyperlipidemias, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and cause glucose intolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see section 9 in WARNINGS). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors. b. Thromboembolism. An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to non-users to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. Cohort studies have shown the relative risk to be somewhat lower, about 3 for new cases and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease associated with oral contraceptives is not related to length of use and disappears after pill use is stopped. A two- to four-fold increase in relative risk of post-operative thromboembolic complications has been reported with the use of oral contraceptives. The relative risk of venous thrombosis in women who have predisposing conditions is twice that of women without such medical conditions. If feasible, oral contraceptives should be discontinued at least four weeks prior to and for two weeks after elective surgery of a type associated with an increase in risk of thromboembolism and during and following prolonged immobilization. Since the immediate postpartum period is also associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than four weeks after delivery in women who elect not to breast feed. c. Cerebrovascular diseases. Oral contraceptives have been shown to increase both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes), although, in general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and non-users, for both types of strokes, and smoking interacted to increase the risk of stroke. In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for nonsmokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 7.6 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk is also greater in older women. d. Dose-related risk of vascular disease from oral contraceptives. A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high density lipoproteins (HDL) has been reported with many progestational agents. A decline in serum high density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the activity of the progestogen used in the contraceptive. The activity and amount of both hormones should be considered in the choice of an oral contraceptive. Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral contraceptive agents should be started on preparations containing 0.035 mg or less of estrogen. e. Persistence of risk of vascular disease. There are two studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40-49 years who had used oral contraceptives for five or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. However, both studies were performed with oral contraceptive formulations containing 50 micrograms or higher of estrogens. 2. ESTIMATES OF MORTALITY FROM CONTRACEPTIVE USE. One study gathered data from a variety of sources which have estimated the mortality rate associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is low and below that associated with childbirth. However, smokers 35 and older and non-smokers 40 and older who use oral contraceptives have a significant increase in mortality higher than those using other methods of birth control. These facts must be weighed in conjunction with failure rates for other methods and the risk associated with subsequent pregnancy. 3. CARCINOMA OF THE REPRODUCTIVE ORGANS. Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. While there are conflicting reports most studies suggest that use of oral contraceptives is not associated with an overall increase in the risk of developing breast cancer. Some studies have reported an increased relative risk of developing breast cancer, particularly at a younger age. This increased relative risk appears to be related to duration of use. Some studies suggest that oral contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors. 4. HEPATIC NEOPLASIA. Benign hepatic adenomas are associated with oral contraceptive use, although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases/100,000 for users, a risk that increases after four or more years of use especially with oral contraceptives of higher dose. Rupture of benign, hepatic adenomas may cause death through intra-abdominal hemorrhage. Studies from Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral contraceptive users. However, these cancers are rare in the U.S. and the attributable risk (the excess incidence) of liver cancers in oral contraceptive users approaches less than one per million users. 5. OCULAR LESIONS. There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia, papilledema, or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately. 6. ORAL CONTRACEPTIVE USE BEFORE OR DURING EARLY PREGNANCY. Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. The majority of recent studies also do not indicate a teratogenic effect, particularly in so far as cardiac anomalies and limb reduction defects are concerned, when taken inadvertently during early pregnancy. The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion. It is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing oral contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral contraceptive use should be discontinued until pregnancy is ruled out. 7. GALLBLADDER DISEASE. Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral contraceptive users may be minimal. The recent findings of minimal risk may be related to the use of oral contraceptive formulations containing lower hormonal doses of estrogens and progestogens. 8. CARBOHYDRATE AND LIPID METABOLIC EFFECTS. Oral contraceptives have been shown to cause a decrease in glucose tolerance in a significant percentage of users. This effect has been shown to be directly related to estrogen dose. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the non-diabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects prediabetic and diabetic women in particular should be carefully monitored while taking oral contraceptives. A small proportion of women will have persistent hypertriglyceridemia while on the pill. As discussed earlier (see WARNINGS 1a and 1d), changes in serum triglycerides and lipoprotein levels have been reported in oral contraceptive users. 9. ELEVATED BLOOD PRESSURE. An increase in blood pressure has been reported in women taking oral contraceptives, and this increase is more likely in older oral contraceptive users and with extended duration of use. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing progestational activity. Women with a history of hypertension or hypertension-related diseases, or renal disease, should be encouraged to use another method of contraception. If women elect to use oral contraceptives, they should be monitored closely and if significant elevation of blood pressure occurs, oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives, and there is no difference in the occurrence of hypertension between former and never users. 10. HEADACHE. The onset or exacerbation of migraine or development of headache with a new pattern which is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause. 11. BLEEDING IRREGULARITIES. Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first three months of use. Non-hormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out. Some women may encounter post-pill amenorrhea or oligomenorrhea, especially when such a condition was preexistent. 12. ECTOPIC PREGNANCY. Ectopic as well as intrauterine pregnancy may occur in contraceptive failures. **PRECAUTIONS:** 1. PHYSICAL EXAMINATION AND FOLLOW UP. A complete medical history and physical examination should be taken prior to the initiation or reinstitution of oral contraceptives and at least annually during use of oral contraceptives. These physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, including cervical cytology, and relevant laboratory tests. In case of undiagnosed persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be conducted to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care. 2. LIPID DISORDERS. Women who are being treated for hyperlipidemias should be followed closely if they elect to use oral contraceptives. Some progestogens may elevate LDL levels and may render the control of hyperlipidemias more difficult. 3. LIVER FUNCTION. If jaundice develops in any woman receiving such drugs, the medication should be discontinued. Steroid hormones may be poorly metabolized in patients with impaired liver function. 4. FLUID RETENTION. Oral contraceptives may cause some degree of fluid retention. They should be prescribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention. 5. EMOTIONAL DISORDERS. Women with a history of depression should be carefully observed and the drug discontinued if depression recurs to a serious degree. 6. CONTACT LENSES. Contact lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist. 7. DRUG INTERACTIONS. Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar association, though less marked, has been suggested with barbiturates, phenylbutazone, phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines. 8. INTERACTIONS WITH LABORATORY TESTS. Certain endocrine and liver function tests and blood components may be affected by oral contraceptives: a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3, increased norepinephrine-induced platelet aggregability. b. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radio-immunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG, free T4 concentration is unaltered. c. Other binding proteins may be elevated in serum. d. Sex-binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged. e. Triglycerides may be increased. f. Glucose tolerance may be decreased. g. Serum folate levels may be depressed by oral contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives. 9. CARCINOGENESIS. See WARNINGS section. 10. PREGNANCY. Pregnancy Category X. See CONTRAINDICATIONS and WARNINGS sections. 11. NURSING MOTHERS. Small amounts of oral contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child. **INFORMATION FOR THE PATIENT: See Patient Package Insert.**

ADVERSE REACTIONS: An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see WARNINGS section). Thrombophlebitis and venous thrombosis with or without embolism. Arterial thromboembolism. Pulmonary embolism. Myocardial infarction. Cerebral hemorrhage. Cerebral thrombosis. Hypertension. Gallbladder disease. Hepatic adenomas or benign liver tumors. The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug-related: Nausea. Vomiting. Gastrointestinal symptoms (such as abdominal cramps and bloating). Breakthrough bleeding. Spotting. Change in menstrual flow. Amenorrhea. Temporary infertility after discontinuation of treatment. Edema. Melasma which may persist. Breast changes: tenderness, enlargement, secretion. Change in weight (increase or decrease). Change in cervical erosion and secretion. Diminution in lactation when given immediately postpartum. Cholestatic jaundice. Migraine. Rash (allergic). Mental depression. Reduced tolerance to carbohydrates. Vaginal candidiasis. Change in corneal curvature (steepening). Intolerance to contact lenses. The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted: Pre-menstrual syndrome. Cataracts. Changes in appetite. Cystitis-like syndrome. Headache. Nervousness. Dizziness. Hirsutism. Loss of scalp hair. Erythema multiform, Erythema nodosum. Hemorrhagic eruption. Vaginitis. Porphyria. Impaired renal function. Hemolytic uremic syndrome. Acne. Changes in libido. Colitis.

OVERDOSAGE: Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea and withdrawal bleeding may occur in females.

ORTHO

ORTHO PHARMACEUTICAL CORPORATION
Raritan, New Jersey 08869-0602

Revised 9/89

IMPRESSIVE NUMBERS

- Over 200 million cycles of experience†
- Available in the familiar Sunday-start ORTHO DIALPAK* Tablet Dispenser

21- and 28-day regimens

ORTHO-NOVUM 777 Tablets

TRADEMARK

norethindrone/ethinyl estradiol

A solid choice for your OC patients

*Trademark
†Based on National Prescription Audit, 1990.
Serious as well as minor side effects have been reported with the use of oral contraceptives. The physician should remain alert to the earliest manifestations of any symptoms of serious disease and discontinue oral contraceptive therapy when appropriate.

Please see complete Prescribing Information, a brief summary of which is on the preceding page.
